In Switzerland also this plant is cultivated with great advantage: but it has not found so good a reception in England as it justly deserves; though there is reason to believe that it will succeed as well in this country as in France or Switzerland, since it is extremely hardy, and capable of resisting the severest cold of our climate. The culture of *lucerne* was attempted in this country about the year 1650, and afterwards discontinued, through failure of success, for many years: but since the discovery and practice of the new method of husbandry, it has been revived with considerable advantage. However writers on agriculture are not agreed as to the best method of cultivating this plant. Mr. Tull observes, that though all our land seems to be either too rich, too poor, or too cold, for raising this valuable plant in the way of the common husbandry, yet he is convinced that in the new method many thousand acres of English land are capable of producing fine crops of it, even for an age together.

The greater degree of moisture, and less heat of this climate, are all of the utmost advantage to this plant when horse-hoed, as that sufficiently prevents the growth of the turf which would destroy it.

In the drier summers in Italy and the south of France, the *lucerne* yields only four or five crops instead of six or seven; but in the driest summers in England, it would succeed the best of all, and give the most numerous crops. The horse-hoeing prevents the turf, and makes the land imbibe the dews, and retain them for the nourishment of the plants; and *lucerne*, in sheltering places, will grow by this means, even in our winter, plants of it having been seen at Christmas of fourteen inches high. Our winters need not be feared in regard to the *lucerne*, for at Neufchatel it is found to stand all the winters very well; yet there the rosemary-plants all die if left out in the winter. This is a proof that the winters are more severe than our's, for it is not one winter in forty that hurts this shrub with us.

In the year 1708, the *lucerne* in Languedoc suffered by the severity of the winter, but this was so sharp, that the olive-trees, and even the walnut-trees, were also killed by it: as no such frosts come among us as to kill our walnut-trees, we need not fear a crop of this plant, for much of it survived even there when those trees perished. In Languedoc the *lucerne* never arrives at any great height, except where it has the advantage of the plough; and in Wiltshire there have been lands sown with it, where it grew but poorly and low; but after the same grounds had been ploughed, and after corn laid down with saint-foin, the *lucerne* plants that were left grew up to a vast height, and were very vigorous, which shews the advantage of the plough; and all this advantage will be regularly given by horse-hoeing, without the destruction of any of the plants. Though the common method of husbandry will not raise *lucerne* to advantage, yet the horse-hoeing husbandry will raise it annually, increasing in value to the owner, and make one of the most profitable articles of it.

The soil to plant it on must be either a hot gravel, or a very rich dry sand, or some other rich warm land that has not an under stratum of clay, and is not too near springs of water. The natural poorness of gravel may be made up by dung and the benefit of the hoe, and the natural richness of the other lands being increased by hoeing and cleansing them from grass, the *lucerne* will thrive with less heat; for what it wanted in one of these qualities must be made up in the other. The best season for planting it in England according to Mr. Tull, is about the middle of April, after the danger of frost is past; for a small frost will destroy the whole crop, when the plants first appear, and too much wet, with cold weather, will rot the seeds in the ground.

The number of *lucerne* plants should be less than those of of saint-foin to an acre, because they grow much larger in this way of management, and each occupies a great space of ground, and produces a larger quantity of hay. The quick growth of this plant requires that it should have large supplies of nourishment, and good room to grow in, and it is better in all things of this kind to err in setting the plants too far distant than in setting them too near.

The most fatal disease incident to *lucerne* is starving; for this reason good culture is necessary to it, and the often turning the earth with the hoe all about it. By this means, a plant, that in the common way of sowing, would not have been more than four or five inches high, will be three feet, and will spread every way, so as to produce a quantity of hay, more like the cutting of a shrub than a plant. The plants should stand at five inches distance in single rows, and the intervals between these rows must be left wide enough for the use of the hoe-plough.

The rows of *lucerne* plants must not be thinned till they are grown up to some height; for while young they are subject to be eaten by the fly, like turnips; and if this destroyer should seize them, after they are reduced to only a competent number, the crop would be rendered much too thin. The hoe-plough is the only instrument that can

bring

bring this plant to perfection, and it must be frequently had in proportion to the number of crops it produces; but then it must be ſtill ſome years, leſt the ploughed ground injure the hay that is made upon it; and when it is come to a turf, and the *lucerne* wants renewing, the four-coulterred plough is the only inſtrument that can prepare the turf to be killed, and cure the *lucerne*. This plough muſt be uſed in the following manner: turn its furrows toward one row, and from the next; that is, plough round one row, and that will finiſh two intervals; and ſo of the reſt. The next ploughing muſt be towards thoſe rows from which they were turned the firſt time, and care muſt be taken that the firſt furrows do not lie long enough on the rows to kill the plants, which will be much longer in winter than in ſummer.

Lucerne can never be expected to ſucceed well any where, let the ſoil be ever ſo good, unleſs it be kept clean from natural graſs. Tull's Horſe-Hoeing Huſbandry, chap. 13.

Mr. Miller, in his directions for the culture of *lucerne*, recommends a light, dry, looſe, ſandy land; which ſhould be well ploughed and dreſſed, and cleared of weeds. The beſt time for ſowing the ſeed, which ſhould not be mixed with oats or barley, as is ſometimes the practice, is in the middle of April, and in a dry ſeaſon. After having well ploughed and harrowed the land very fine, he adviſes to make a drill quite acroſs the ground, almoſt half an inch deep, into which the ſeeds ſhould be ſcattered very thin, and to cover them over with earth ſomewhat more than a quarter of an inch thick. Another drill ſhould then be made about a foot and a half from the former, ſowing the ſeeds in the ſame manner as before, and thus proceeding through the whole ground. In this way, an acre of land will require about ſix pounds of ſeeds. If this crop be well cultivated, it will continue many years, and be as good as when firſt ſown. By ſowing the ſeed in rows, the plants will have room to grow, and the ſoil between them may be ſtirred more eaſily with a hoe, in order to deſtroy the weeds and encourage the growth of the plants. This hoeing ſhould be repeated in dry weather two or three times, while the plants are young, for more effectually deſtroying the weeds. In the beginning of Auguſt the plants will have grown to the height of two feet or more, and the flowers will begin to appear: they ſhould then be cut in a dry ſeaſon; and when they are made into hay, often turned, that they may ſoon dry and be carried off the ground; for if they be long upon the roots, they will prevent their ſhooting. Mr. Tull recommends to cut the *lucerne* before it begins to flower: the richeſt *lucerne* hay, he ſays, is cut while the ſtalks are ſingle, without any collateral branches, and in this caſe there is not uſually ſo much as the bud of a flower to be ſeen on the plants. After the crop is taken off, the ground ſhould be ſtirred between the rows with a hoe, to kill the weeds and looſen the ſurface; and thus in the beginning of September, there will be ſhoots four or five inches high, which may be fed down with ſheep until November. In the beginning of February, the ground between the rows ſhould again be ſtirred with the hoe, without injuring the crown of the roots. By this management, in a warm ſoil, the ſhoots will be five or ſix inches high in the middle of March; and they may be fed down, if fodder be wanted, till a week in April; after which it ſhould be left to grow for a crop, which will be fit to cut in the beginning of June; and when the ground is cleared, let it be ſtirred again with a Dutch hoe, and thus there will be another crop fit to cut in the middle or latter end of July: after which it ſhould be fed down again in autumn with larger cattle, obſerving not to let them remain after the roots have done ſhooting, leſt they eat down the crown of the roots below the buds, which would conſiderably damage, if not deſtroy them. In this way you may continue conſtantly to have two crops to cut, and two feedings upon this plant, and in good ſeaſons there may be three crops cut and two feedings; which will be a great improvement, eſpecially as this plant will grow upon dry barren ſoils, and be of great uſe in dry ſummers, when graſs is often burnt up. And as it is an early plant in the ſpring, it will be of great ſervice when fodder is ſcarce, becauſe it will be fit to feed at leaſt a month before graſs or clover. The beſt ſeed is procured from Switzerland and the northern parts of France; but the ſeed may be ſowed in England, by ſuffering ſome of the plants to grow uncut till the ſeeds are ripe, and then cutting them and laying them to dry in an open barn, expoſed to the air, but defended from the wet. When they are quite dry, the ſeed may be threſhed out, cleanſed from the huſk, and preſerved in a dry place. This ſeed, ſays Mr. Miller, is preferable to any brought from abroad. This writer ſays great things of *lucerne* being ſown by itſelf, unmixed with any other ſeed. When the *lucerne* is made into hay, it muſt be often turned, and expoſed a fortnight before it can be houſed; and it ſhould then be kept in cloſe barns, where it will remain good for three years. One acre of this fodder has been reckoned ſufficient to keep three horſes for a whole year; and three acres of it have fed ten cart-horſes, from the end of April to the beginning of October, without any other food, though they have been conſtantly worked. *Lucerne* is beſt uſed green, and will ſerve the purpoſe both of hay and corn. Miller's Gard. Dict.

Mr. Rocque, a late writer on the culture of *lucerne*, advances a different opinion from that of moſt others on this ſubject. He recommends the ſtrongeſt land, which ſhould be prepared in the ſame manner as for barley, being ploughed, harrowed, and cleaned from weeds: he adviſes before the laſt ploughing, to manure the land with freſh ſtable-dung, which ſhould be laid on in a ſtate of full fermentation, and ploughed in as ſoon as poſſible: after which the land muſt be harrowed, and the *lucerne*-ſeed ſown broad caſt, not in drills, in fine weather, after the rate of about fourteen pounds to an acre; afterwards it ſhould be harrowed again with a light or buſh-harrow, and, laſtly, rolled to ſettle the ground and break the clods. The quantity of tillage and time of ſowing muſt be regulated by the nature of the ſoil. Heavy ſtrong land will require more ploughings and harrowings, and to be later ſown, than light land: and, for the firſt time, a trench-ploughing would be of great advantage. *Lucerne*, he ſays, may be ſown from the beginning of March to the end of May, but April, in dry weather, is the beſt time. Barley or oats may be ſown with the *lucerne*, in the proportion of a buſhel of either of the former, which ſhould be ſown firſt on an acre, to fourteen pounds of the *lucerne*. When the plants are one year old, Mr. Rocque adviſes, to go over the land, early in the ſpring and in dry weather, with a large harrow, as often as is ſufficient to root up annual weeds and graſs; to add a dreſſing of rotten dung: and in the ſecond ſpring after ſowing, to plough the ground with a drill-plough, having a round ſhare, without a fin or feather, and without a coulter, which ploughing ſhould be annually repeated: after lying for a few days to dry and mellow, it ſhould be harrowed down. This writer ſays that he has ſeen *lucerne* mowed five times in a ſeaſon, yielding, at the five mowings, neatly eight loads of hay per acre. Mr. Rocque is of opinion, that it is by no means adviſeable to ſow the ſeed in England, ſince it may be imported ſo cheap, that the ſeedſman can afford to retail it at one pound.

Others have recommended the method of ſowing the *lucerne* ſeed in a nurſery, and afterwards removing the young plants, with their ſtalks and tap-roots cut off, and tranſplanting them in the field where the crop is to be produced. The plants in this way of management are tranſplanted into holes filled with water, in rows three feet four inches diſtant from each other, and about a foot from each other in the rows. An acre of tranſplanted *lucerne*, it is ſaid, will bring in 3*l.* a year, clear of all expences, for a conſiderable time. M. de Chateauvieux has made many experiments on the method of cultivating *lucerne* on beds or ridges, which are to be a little more than three feet broad, and tranſplanting his plants in a ſingle row upon each ridge, at the diſtance of about ſix inches. In this way he obtained above five tons of *lucerne* hay per Engliſh acre, reckoning his crops at an average of four years; and it is obſervable, that his crops were improving, though they had no manure, and were only hoed with his cultivation. This method of planting on ridges ſeems to be the beſt method, with regard to produce, of any that has been yet practiſed: but it might be moſt adviſeable to ſet the plants at nine inches diſtance in the rows, and to make the ridges four one-half or five inches broad, for the convenience of hoeing them. Good crops of green *lucerne* may be reckoned from twenty to forty tons, and the average about twenty-five tons per acre, when drilled on the level; but conſiderably more if upon ridges and horſe-hoed. Farmer's Diction. art. *Lucerne*.

LUCERNE, in *Ichthyology*, a name given by the Venetians to the fiſh commonly called the DRAKOSCORE. It is a ſpecies of trachinus, with many beards on the lower jaw.

LUCIANISTS, or LUCANISTS, a religious ſect, ſo called from Lucianus, or Lucanus, a heretic of the ſecond century, being a diſciple of Marcion, whoſe errors he followed, adding ſome new ones to them.

Epiphanius ſays, he abandoned Marcion; teaching, that people ought not to marry, for fear of miſtaking the Creator: and yet other authors mention, that he held this error in common with Marcion, and other Gnoſtics. He denied the immortality of the ſoul; aſſerting it to be material.

There was another ſect of *Lucianiſts*, who appeared ſome

time after the Arians. They taught, that the Father had been a Father always, and that he had the name even before he begot the Son; as having in him the power, or faculty, of generation: and in this manner they accounted for the eternity of the Son.

LUCID *intervals*, the fits of lunatics, or maniacs, wherein the phrenzy leaves them in poſſeſſion of their reaſon.

It is ſaid, lunatics are capable of making a will in their *lucid intervals*.

LUCIDA *corona*, a fixed ſtar of the ſecond magnitude, in the northern crown. See CORONA *borealis*.

LUCIDA *hydræ*, in *Aſtronomy*. See COR *hydræ*.

LUCIDA *lyræ*, a bright ſtar of the firſt magnitude, in the conſtellation LYRA.

LUCIDUM *ſeptum*. See SEPTUM.

LUCIFER, in *Aſtronomy* and *Mythology*, a name given to the planet Venus, when ſhe appears in the morning before ſun-riſe.

LUCIFERA, in *Mythology*, a ſurname given to Diana, under which title ſhe was invoked by the Greeks in childbed. She was repreſented as covered with a large veil, interſperſed with ſtars, bearing a creſcent on her head, and holding in her hand a lifted flambeau.

LUCIFERIANS, a religious ſect, who adhered to the ſchiſm of Lucifer, biſhop of Cagliari, in the fourth century, who was baniſhed by the emperor Conſtantius, for having defended the Nicene doctrine concerning the three perſons in the godhead.

St. Auguſtine ſeems to intimate, that they believed the ſoul, which they conſidered as of a carnal nature, to be tranſmitted to the children from their fathers. Theodoret ſays, that Lucifer was the author of a new error. The *Luciferians* increaſed mightily in Gaul, Spain, Egypt, &c. The occaſion of the ſchiſm was, that *Lucifer* would not allow any acts he had done to be aboliſhed. There were but two *Luciferian* biſhops, but a great number of prieſts and deacons. The *Luciferians* bore a peculiar averſion to the Arians.

LUCINA, of *lux*, *light*, in *Mythology*, a deity who preſided over the labour of women and the birth of children. This title is ſometimes given to Diana, but moſt commonly to Juno.

LUCIOLA, in *Botany*, a name uſed by ſome authors for the ophioglоſſum, or adder's tongue.

LUCIOPERCA, the *pike-perch*, a fiſh caught in the Danube and other large rivers, and in the lakes of Germany, and eſteemed a very good one for the table. Others have called it by the names *ſchidus* and *zingumachus*. It is a fiſh that grows to a very conſiderable ſize, being frequently caught from two feet to three or four in length; it is of a longer ſhape than the river-perch, and grows narrower toward the tail; its ſnout is alſo more pointed and longer, and its back much leſs prominent than that of the common perarch; its figure, upon the whole, more approaches to that of the pike than of the perarch; its belly is however broad and flat; and on the anterior part of the back, toward the head, there is a furrow in the middle. The ſcales are ranged very cloſely together, and are imbricated round their edges; the breaſt has no ſcales; the ſides are of the ſame colour with thoſe of the common perarch, a yelloweſh brown, and its belly and fins are red, but leſs ſo than in the common perarch.

LUCIUS, in *Ichthyology*. See PIKE.

LUCIUS *marinus*, the *ſea-pike*, a name given by ſome authors to the fiſh more uſually called the MERLUCIUS, and in Engliſh the HAKE.

LUCIUS *marinus*, is alſo uſed by many authors for the SUDIS, called alſo by ſome *ſphyræna*.

LUCIUS *terreſtris*, the *land-pike*, in *Zoology*, the name of a very ſingular ſpecies of American lizard, which has the ſhape, ſcales, &c. of the pike-fiſh; in the place of the fins of that fiſh it has four legs, but theſe are ſo weak and ſlender that it makes no uſe of them in walking, but crawls along upon the ground in the manner of a ſnake, and draws its legs after it; it grows to about fifteen inches long, with a proportionable thickneſs; it is all over covered with ſmall, ſtrong, and gloſſy ſcales, of a ſilvery grey. In the night they retire into holes and caverns, and make a very diſagreeable and loud noiſe, much louder than the croaking of frogs. They ſeldom ſtir out of their holes, unleſs in the dusk of the evening; and if they are ever met with in the day-time, their ſtrange motion ſurpriſes all who ſee them.

LUCULLEUM *marmor*, in the *Natural Hiſtory of the Ancients*, the name of a hard ſtony kind of marble, of a good fine black, and capable of an elegant poliſh, but little regarded from its want of variegations. When freſh broken, it is ſeen to be full of ſmall, but very bright ſhining particles, appearing like ſo many ſmall ſpangles of tale. It had its name from the Roman conſul Lucullus, who firſt brought it into uſe in that city. It is common in Italy, Germany, and France. We have much of it imported, and our artificers call it the *Namur* marble, the Spaniards call it marble of *Buega*. Hiſt. of Foſſ. p. 466.

LUCULLIAN *games*, in *Antiquity*, were annual games decreed by the proviace of Aſia, about the year 70 before Chriſt, in honour of the exploits of Lucullus.

LUDI *Circenſes*. See CIRCENSES.

LUDI *florales*. See FLORALES.

LUDI *juvenibi*. See DECEMBER.

LUDICROUS *games*. See GAMES.

LUDUS *Helmontii*, ſo called from Van Helmont who extolled its medicinal virtues, in *Natural Hiſtory*, an opake foſſil of an irregular ſhape, but of a very regular and ſingular internal ſtructure. It is of an earthy hue, and always divided into ſeparate maſſes, by a number of veins of a different colour, and purer matter than the reſt. Theſe maſſes, into which it is divided, are ſometimes ſmall and pretty regularly figured; in which caſe, they are called *tali* or *tali*, *dives*; but they are more frequently of no regular ſhape at all. There are others of them craſſitated, or compoſed of many coats, diſpoſed one over another about a central nucleus. In theſe the *ſepta*, or dividing veins, are very thin and fine, in the others thicker.

It is only theſe *ſepta* that are uſed in medicine, being given in nephritic complaints with ſucceſs. The doſe is from a ſcruple to a drachm.

LUDWIGIA, in *Botany*, a genus of the *tetrandria monogynia* claſs. Its characters are theſe: the flower whoſe empalement is compoſed of one leaf, cut into ſegments at the top, conſiſts of four ſpear-ſhaped petals, which are equal and ſpread open; in the center of the flower is ſituated the four-cornered peral, attended with four ſtamina; the germen which ſits under the flower, becomes a four-cornered fruit, crowned with the empalement, and has four cells, which are filled with ſmall ſeeds. Miller mentions only one ſpecies of this plant, which grows naturally in South America; Linnæus reckons three ſpecies.

LUES, in a general ſenſe, is uſed for a diſeaſe of any kind.

LUES, in a more particular ſenſe, is reſtrained to contagious and peſtilential diſeaſes.

LUES, in the common and modern uſe of the word, eſpecially when joined with *Gallica*, or *venerea*, is reſtrained only to the French pox. See VENEREAL *diſeaſe*.

LUFF, a ſea-term, the ſame with LOOF.

LUFFA, *Egyptian cucumber*, in *Botany*, is a ſpecies of the *momordica* in the Linnæan ſyſtem. See *Mala* BALSAM *apple*.

LUG-*ſail*, a name uſed in ſome parts of England for a ſmall fiſh of the turbot kind, or rather a middle kind between that and the plaiſe. It is the ſame with the *ſaggio*.

It is the *rhomboides* of Rondeletius, and the *rhombus non aculeatus ſquamoſus* of Willughby.

We have it on our own ſhores; and the Corniſh people, who frequently catch it, call it the *lug-a-leaf*. It has no rough fines at the roots of its fins. Its eyes are large, and ſet at a conſiderable diſtance, and it is covered with extremely minute ſcales. It is very flat and thin, and of an aſh-colour.

It is a very ſingular ſpecies of fiſh, differing, in ſome particulars, from both thoſe genera in which it ſeems allied. It differs from the plaiſe kind, in that it has the eyes, fins, &c. of the turbot, or rhombus; and from that fiſh, in that it is ſcaly as the plaiſe, and the other fiſh of that genus.

LUG-*ſail*, in *Sea-language*, is a ſquare ſail, hoiſted occaſionally on the maſt of a boat or ſmall veſſel, upon a yard which hangs nearly at a right-angle with the maſt. Theſe are chiefly uſed in the *barca longa*, navigated by the Spaniards in the Mediterranean.

LUGGS, the Engliſh name for a peculiar ſpecies of inſect, found in great plenty on the ſhores of Cornwal. It is of the nature of the *ſcolopendra*, and is called by Mr. Ray *vermis ſcolopendroides*. It grows to twelve inches long, and has inſtead of legs nineteen pair of ſtiff briſtles, all which ſtand toward the head part of the creature. The tail is at leaſt five inches long when full grown, and has no mark of them. Its body is rounded, and much reſembles the body of the common earth worm, and is of a fleſh-colour, or pale red. It has no forceps.

LUGMON, in natural hiſtory, a name given by the people of the Philippine Iſlands to a ſpecies of turtle, the female of which has a tuft of red feathers, of a pale blood-colour, on her breaſt, which have greatly the appearance of a wound, ſo much that any body would really be deceived.

LUJULA, *wood-ſorrel*, in *Medicine*. See SORREL.

LUKE, or *Goſpel of St. Luke*, a canonical book of the New Teſtament, written by *Luke* the Evangeliſt, who was

probably, an early Jewish believer, soon after the ascension of Christ; if not a hearer of Christ and one of the seventy disciples. *Luke* was by profession a physician; and is supposed to have died a natural death in the eighticth or eighty-fourth year of his age, about the year of Christ 70.

Some think it was properly St. Paul's gospel, and that when that apostle speaks of his gospel, he means what is called *St. Luke's*. Irenæus says, that *St. Luke* digested into writing what St. Paul preached to the Gentiles; and Gregory Nazianzen tells us, that *St. Luke* wrote with the assistance of St. Paul. This Gospel, as well as the Acts of the Apostles, written by this evangelist, are supposed to have been two parts of the same volume, and to have been published in the year of Christ 63 or 64, as some say, at Alexandria, but according to others, in Greece.

St. Luke, says a modern writer, is pure, copious, and flowing in his language, and has a wonderful and entertaining variety of select circumstances in his narration of our Saviour's divine actions. He acquaints us with numerous passages of the evangelical history, not related by any other evangelist: both in this gospel and Apostolical Acts, he is accurate and neat, clear and flowing with a natural and easy grace: his style is admirably accommodated to the design of history; it had a very considerable resemblance to that of his great master St. Paul; and, like him, he had a learned and liberal education, and appears to have been very conversant with the best classics; for many of his words and expressions are exactly parallel to their's. Blackwall's Sacred Classics.

St. LUKE's *day* is a festival observed on the 18th of October.

St. LUKE's *hospital*. See HOSPITAL.

LULANIS, in *Botany*, a name given by some of the ancient Greeks to a plant, used very frequently for a yellow colour in dying, and by the ladies for tinging their hair yellow, the favourite colour of those times. Neuphytus explaining this word, says, that it signified the same with isatis, glastum, or woad; and several others have been of that opinion, though very absurdly, since the glastum or woad dies a blue colour, not a yellow; and by no means answers the description of the *lulanis*, which is the same with the LUTUM, or *lutea herba* of the Romans, and with the *genistella tinctoria*, or DYERS-*weed* of these times.

LULLY's *art*. See ART.

LUMBAGO, pains about the loins, and the small of the back; such as precede ague-fits, and fevers.

They rise commonly from fulness, and acrimony; in common with a disposition to yawning, shuddering, and erratic pains in other parts, and go off with evacuation, generally by sweat and other critical discharges of fevers. This disorder is a kind of RHEUMATISM in the loins.

LUMBAL *glands*. See GLAND.

LUMBAL *nerves*. See NERVE.

LUMBARIS, an epithet given to those branches of the aorta which carry the blood to the muscles of the loins.

LUMBARIS is also applied to certain veins which bring back the blood from the loins into the trunk of the vena cava.

There is also a muscle of the thigh which bears this name. See PSOAS.

LUMBRICAL, LUMBRICALIS, an appellation given to four muscles of the hand, and as many of the foot, which act as adducents of the fingers and toes.

The word is formed from *lumbricus*, *worm*, on account of their figure, and smallness, which give them a resemblance to worms: on which account they are called *vermiculares*.

LUMBRICALES *manus* are muscles of the hands, commonly supposed to be nothing but branches of the tendons of the perforans, which go to the inside of the first bone on each finger, and are supposed to contribute to the variety of motions with the fingers, by giving a diversion to the direct actions of the other muscles; but, simply, they only serve to draw the fingers towards the thumb. Though Mr. Cowper observes that some of them have distinct origins, and suspects, that the rest may have so too, and therefore makes them distinct muscles.

LUMBRICALES *pedes* are muscles of the foot, which arise, as in the hand, one from each tendon of the perforans, or profundus; and go to the inside of each of the lesser toes.

LUMBRICUS, in *Zoology*. See EARTH *worm*.

LUMELLA, in the *glass-trade*, the round hole in the floor of the tower of the leer, which is directly over the working furnace, and by which the flame is let into the tower.

LUMINOSA *simia*. See SEMIA.

LUMINOUS *column*, and *fire*. See the substantives.

LUMINOUS, *sensations*, have been observed from human bodies, as also from those of brutes. The light arising from currying a horse, or from rubbing a cat's back, are known to most. Instances of a like kind have been known on combing a woman's head. Bartholin gives us an account, which he intitles *mulier splendens*, of a lady in Italy, whose body would shine, whenever slightly touched with a piece of linen. These effluvia of animal bodies have many properties in common with those produced from glass; such as their being lucid; their snapping, and their not being excited without some degree of friction; and are undoubtedly electrical, as a cat's back has been found strongly electrical when stroaked. See ELECTRICITY, and LIGHT.

Human bodies not only appear *luminous*, but even the exhalations from them adhering to their cloathing will cause it to shine likewise.

LUMINOUSNESS *of the sea*. See SEA and FIRE.

LUMME, in *Ornithology*, the name of a water-fowl of the colymbus kind, called by authors *colymbus in rictus*, common about Iceland and some parts of Norway, and scarce known in other parts of the world.

It is a beautiful bird of the size of a duck; it has a black and sharp beak of two inches long, and its head and neck are covered with grey feathers, running each way to a sharp edge, and making the appearance of a hood, or friar's cowl. Its back and wings are black, variegated with square specks of white, and just under the neck there is a large black square spot. This runs down the back also to five inches in length, and is about two inches broad, and beautifully variegated with black, white, and grey. Its belly is white, its legs are short, and its feet webbed. The people, where it is common, hold it as sacred in some measure, and are afraid of killing it in some places; but the Icelanders make it their principal food, and are very dextrous at catching it with snares. Ray.

LUMP-*fish*, the *cyclopterus lumpus* in the Linnæan system, in *Ichthyology*, a thick and short sea-fish, called the *sucker*, also the *sea-mouse*, and by the Scotch, the *cock-paddle*.

It is a thick and very ill-shaped fish. Its belly is broad and flat, and its back rises to a ridge; its colour is a mixture of blackish and red; its belly is red; it has no scales, but is covered with a rough skin, which is full of sharp tubercles; and on each side it has three rows of prickles or crooked thorns; it has two fins on the back, the first thick, cartilaginous, or rather fleshy, and having no rays or nerves, and another below it supported by nine rays; its mouth is large, and its jaws are furnished with vast numbers of small teeth; beneath the pectoral fins is the part by which it adheres to the rocks, &c. consisting of an oval aperture, surrounded with a fleshy, muscular and obtuse soft substance, edged with smaller threaded appendages, which concur in so many clusters.

It is caught in many parts of the English seas, and is common in the fishmongers shops in London, but it is not much esteemed, being both flabby and insipid. On the coast of Sutherland it abounds in spring, and is devoured by the seals, which may be known by the smoothness of the water above the spot; the oil serving to still the agitation of the waves. The roe of this fish is remarkably large, and is boiled to a pulp, and eaten by the Greenlanders. See *Tab.* II. *of Fish.* N° 21.

LUMP *of flesh*, in the *Manege*. See BOUILLON.

LUMPEN, in *Ichthyology*, the name of a long-bodied fish of the mustela kind, common in the markets at Antwerp.

It is of a long and round body, growing gradually slenderer to the tail. Its colour is a greenish yellow, with black broad lines on the back, placed transversely; and it has a little redness at the end of its tail.

The *lumpen* is the *galea pisces*, or *mustela altera* of Gesner, and others. It is a species of the *blennus*, distinguished by Artedi by the name of the *blennus*, with fins like cirri under its neck, and transverse streaks on the back. The cirri are bifid.

LUNA, in *Astronomy*. See MOON.

LUNA, in the jargon of the *Chemists*, signifies SILVER; so called from the supposed influence of the moon thereupon.

The medicinal virtues of this metal, Dr. Quincy says, are none at all, until it has undergone very elaborate preparations.

LUNA *cornea*, in *Chemistry*, is the combination of marine acid with silver. To make this combination, the silver is first dissolved in nitrous acid; to this solution marine acid, or more usually common salt dissolved in water, is added. The mixture soon becomes turbid, and a copious precipitate is formed in it, which has always the appearance

pearance of curd. The solution of salt is added, till no more precipitate is formed. The precipitate, when separated from the liquor that swims over it, is called *luna cornea*; because if this matter be exposed alone to fire, the acid carries off with it a portion of the silver, and the remaining matter melts, assuming the form of a horny substance.

The best method of reducing *luna cornea*, or of separating silver from marine acid, according to Margraaf, is to dissolve half an ounce of fine silver in aqua fortis, to precipitate it by a sea salt, and edulcorate the precipitate, which will then weigh five drams fifteen grains. For the reduction of this precipitate, mix it with an ounce and a half of dry volatile sal ammoniac, triturate them well together with a little water during a quarter of an hour; then add three ounces of mercury obtained from cinnabar by means of quick-lime, and continue to triturate during some hours with a little more water. Thus an amalgam will be formed, which being washed from a white powder and dried, will weigh three ounces and half a dram. By distillation of this amalgam, a residuum of silver, four grains less than the original half ounce, will be obtained. By subliming the white powder, which weighs five drams, three grains of silver will be obtained; but if the amalgam and white powder be distilled together, the operation will fail, and the *luna cornea* be recomposed. Berlin Mem. 1749. M. Beaume says, that *luna cornea* may be reduced without loss by fusion with four times its weight of fixed alkali.

Luna cornea mixed with sea salt and tartar rubbed on brass gives a silver like appearance; and is the substance employed for the silvering of the dial-plates for clocks. A more substantial silvering may be given by the above mixture, if the piece of brass to be silvered be previously heated considerably, and cleaned with a scratch brush, and if the operation be repeated, till the silver seems to be sufficiently thick. The brass having a stronger disposition to unite with the marine acid than the silver has, separates this acid from the silver, which is then precipitated upon the surface of the brass plate. The *luna cornea* will also serve, in the examination of mineral waters or of any other liquor, to dissolve if they contain marine acid in whatever base it be engaged, except metallic bases; for if these waters contain the smallest quantity of marine acid, a *luna cornea* will be precipitated by them from a solution of silver in nitrous acid, and this *luna cornea* is known by its acid-like appearance. Dict. Chem. Eng. edit.

LUNA *Crystals of*, See CRYSTAL.

LUNA, *Vitriol of* See VITRIOL.

LUNA *marina*, in *Ichthyology*, a name by which Gesner has called a peculiar species of *flat-fish*, called also the *sea-sun*. See SOLEIL *de mer*.

LUNA *piscis*, in *Ichthyology*, a name by which some have called the mola, which we usually call in English the SUN-*fish*.

LUNÆ, *Lac*. See the article LAC *lunæ*.

LUNÆTRIA, a term inscribed by some affected writers on medicine for a fever, which they say is curable in one period of the moon.

LUNALE *bezoardicum*. See BEZOARDICUM.

LUNAR, something relating to the MOON.

LUNAR *cycle*. See CYCLE.

LUNAR *month*. See MONTH.

LUNAR *year*, consists of three hundred and sixty-four days, or twelve synodical months. See YEAR.

In the first ages, the year used by all nations was *lunar*; the variety of course being more frequent in this planet, and, of consequence more conspicuous, and better known to men, than those of any other. The Romans regulated their year, in part, by the moon, even till the time of Julius Cæsar: the Jews too had their *lunar* months. Some rabbins pretend, that the *lunar* month did not commence till the moment the moon began to appear; and that there was a law, which obliged the person who discovered her first, to go and inform the sanhedrin thereof. Upon which the president solemnly pronounced the month begun, and notice was given of it to the people by fires lighted on the tops of mountains. But this appears somewhat chimerical.

LUNAR *dial*, *eclipse*, *horoscope*, and *rainbow*. See the several substantives.

LUNARE *os*, in *Anatomy*, is the second bone in the first row of the carpus. It has its name from the Latin, *luna*, the moon, because one of its sides is in form of a crescent.

The articular sides in this bone are four in number. One convex, for the basis of the radius; one semi-lunar, for the os scaphoides; one almost triangular, for the os cuneiforme; and one hollow, which, with the hollow side of the os scaphoides, forms a cotyloide cavity for the head of the os magnum. The convex side, together with that of the os scaphoides, forms an oblong convexity, answering to the oblong concavity in the basis of the radius. The outer and inner surfaces are small and rough. This bone would somewhat more properly be named *os semi-lunare*, than *lunare*, &c. See Winslow.

LUNARIA, in *Botany*. See HONESTY.

LUNARIA, in *Natural History*, is also cited by some authors for the SELENITES.

LUNARIS *cochlea*, in *Natural History*, the name of a genus of shells of the snail-kind, the distinguishing character of which is their having a perfectly round mouth. These are univalve, umbilicated shells, with a depressed clavicle, and a surface sometimes smooth, but more frequently striated, furrowed, laciniated, or covered with tubercles. See COCHLEA.

It is said, that Archimedes took the invention of the screw, so famous ever since his time, and still called after his name, from the form of this shell; and it is generally allowed, that architects have taken the hint of their winding flights of stairs from it.

The small species of crab, called *bernard the hermit*, often lodges itself in a shell of one of these animals, after the creature to whom it belonged is dead. One species of this genus is called the *rotunda*, from its round shape. This is so large as to contain two quarts of water; and from an old practice of using this species by way of an oil-jar in families, it obtained the name of *aduria*. There is a peculiar species, called the *dauphin-shell*, which is elegantly furnished with rows of points of a jagged form on all its spires; and the shell, called the *sperm*, is another species of this genus, the volume of which are in the same manner furnished with points; but in this species they are smoother and sharper than in the dauphin-shell. Kondeletius has given the name *echinosphera* to one, which is all over covered with rough tubercles. And there is one species of this shell brought from America, which is very large, and of a fine pearly coat within. The workmen in toys take much of what they use from it; and what we imagine the inside of the nacre, or mother of pearl, is often no other than the inner coat of this shell. Of this genus there are enumerated twenty-one different species. Hist. Nat. Eclar. par ii. p. 251.

LUNATIC, LUNATICUS, a person affected, or governed, by the moon. Hence, epileptics were anciently called *lunatici*, because the paroxysms of that disease seem to be regulated by the changes of the moon. Thus Galen, De Diebus criticis, lib. iii. says, the moon governs the periods of epileptic cases; and others referred the disease entirely to this planet. Areteus de Dunamis Morbis lib. i. cap. 4. See Mead's Treatise concerning the influence of the Sun and Moon upon the human Bodies, p. 38. 40, &c.

Mad people are still called *lunatics*, from an ancient but now almost exploded opinion, that they are much influenced by that planet. A much sounder philosophy hath taught us, that if there be any thing in it, it must be accounted for, not in the manner the ancients imagined, nor otherwise than what the moon has in common with other heavenly bodies, occasioning various alterations in the gravity of our atmosphere, and thereby affecting human bodies. However, there is considerable reason to doubt the fact; and it is certain that the moon has no perceivable influence on our most accurate barometers.

The stat. 17 Ed. II. cap. 10. ordains that the king is to provide that the lands of *lunatics* be safely kept, and they and their families maintained by the profits; and the residue shall be kept for their use, and be delivered to them when they come to their right mind; the king taking nothing to his own use; and if the parties die in such state, the residue shall go to their executors or administrators. A warrant is now issued by the king, under his royal sign manual, to the chancellor or keeper of his seal, to perform this office for him.

Lunatics are not legally accountable for any crimes they commit in this state. And also, if a man in his sound memory commits a capital offence, and before arraignment for it, he becomes mad, he ought not to be arraigned for it: and if, after he has pleaded, the prisoner becomes mad, he shall not be tried: if after he be tried and found guilty, he loses his senses before judgment, judgment shall not be pronounced: and, if after judgment, he becomes of non-sane memory, execution shall be stayed.

For the marriage of *lunatics*, See MARRIAGE.

LUNATION, the period, or space of time, between one new moon and another; also called *synodical month*. See CYCLE and EPACT.

LUNDA, in *Zoology*, a name by which Wormius, Hyler, and some others, have called the bird commonly known by the name of *anas arctica Clusii*. See DUCK.

LUNDRESS, or *Old Hundress*, a sterling silver penny; which had its name from being coined only in London, and not at the country mints.

LUNE, LUNULA, in *Geometry*, a plane in form of a crescent, or half-moon, terminated by the circumference of two circles, that intersect each other within it.

Though the quadrature of the entire circle was never yet effected, yet geometricians have found out the squares of many of its parts. The first partial quadrature was that of the lunula given by Hippocrates of Scio, or Chios; who, from being a shipwrecked merchant, commenced geometrician. See CIRCLE and QUADRATURE.

Let AEB (*Tab. III. Geometry, fig. 39.*) be a semicircle, and $G \cdot = \frac{1}{2} GB$; with the radius BC describe a quadrant AFB, then will AEBFA be Hippocrates's *lune*.

And since $BC^2 = 2GB^2$, the quadrant AFBC will be equal to the semicircle AEB: taking away, therefore, from each the common segment AFBGA; AEBFA = to the triangle ACB = GB².

The quadrature of the *lunula* is generally ascribed to Hippocrates of Chios; but Proclus tells us expressly, that it was found by Œnopides of Chios. See Mr. Hermus in Mem. de l'Acad. de Berlin, tom. iii. p. 410. who has given us a narration about this Œnopides.

LUNE, in *Fortification*. See DEMI-lune.

LUNETTE, among, in the *Natural History of the Ancients*, the name of that species of white marble, now known among us by the name of the *Carrara marble*, and distinguished from the statuary kind by its greater hardness and less coherence. It was ever greatly esteemed in building and ornamental works, and is full full. It is of a very fine and fine texture, of a very pure white, and much more transparent than any other of the white marbles. It has always been found in great quantities in Italy, and is so to this day.

LUNES, or LOWRES, in *Falconry*, feathers or longfeathers in the tail or hawks.

LUNETTE, in *Fortification*, an inveloped counterguard, or elevation of earth, made beyond the second ditch, opposite to the places of arms; differing from the ravelins only in their situation.

Lunettes are usually made in ditches full of water, and serve to the same purpose as fausbrayes, to dispute the passage of the ditch.

Lunettes are placed on both sides of the ravelin, as D, D, *Tab. VIII. Fortification fig. 47.* to increase the strength of a place: they are constructed by bisecting the faces of the ravelin with the perpendicular LN, on which are let off 30 toises from the counterscarp of the ditch, for one of its faces; the other face PN is found by making the semigorge TP of 25 toises; the ditch before the *lunettes* is 12 toises, the parapet 3 and the rampart 8.

There is sometimes another work made to cover the salient angle of the ravelin, such as A, called BONNET, whose faces are parallel to those of the ravelin, and whose prolonged sides of the *lunettes* of the ditch before it being 10 toises.

There are likewise found *lunettes*, whose faces are drawn perpendicular to those of the ravelin, within a third part from the salient angle; and their semigorges are only 20 toises. Mr. Muller recommends the face PN to be perpendicular to that of the bastion, which would then defend it in a direct manner; and if the semigorges of the lunettes A were only 7 or 8 toises, it would be less expensive, and its ditch and the covert-way before it would be better defended by the *lunettes*. Elem. of Fortif. p. 36.

LUNETTE, in the *Manege*, is a half horse-shoe, or such a shoe as wants the ipunges, i. e. that part of the branch which runs towards the quarters of the foot.

LUNETTES is also the name of two small pieces of felt, made round and hollow, to clap upon the eyes of a vicious horse that is apt to bite, and strike with his fore feet, or run will not suffer his rider to mount him.

LUNGS, in *Anatomy*, a part of the human body, composed of vessels, and membranous vesicles, serving for respiration. See BREATH.

The lungs are connected, above to the fauces, by means of the trachea; and below, to the vertebræ of the thorax, and to the sternum and diaphragm, by means of the pleuræ. They are divided into two great lobes of a reddish colour in children, grayish in adults, and livid in old age, by the mediastinum and heart, and those again into others less; the right sometimes into three, by means of some fissures running from the fore to the back edge. At the lower edge of the left lung, there is an indented notch or fissure opposite to the apex of the heart, which is therefore never covered by that lung even in the deepest expirations, and consequently the apex of the heart and pericardium may always strike against the ribs. The great lobes, when inflated, resemble each of them a horse's hoof in figure, but together they are more like an ox's inverted, convex next the ribs, concave next the diaphragm, and irregularly depressed near the mediastinum and heart. See *Tab. Anat. Physiolog. fig. 12. lit. t. t. fig. 14.*

The substance of the *lungs* is membranous; consisting chiefly of innumerable cells, or vesicles, which seem to be nothing but expansions of the membranes of the BRONCHIA, to which they hang like grapes in clusters: for that by blowing into one of the branches of the bronchia, those cells, or vesicles, belonging to it, are blown up; the rest, which do not, remaining still flaccid and unstirred.

These clusters of vesicles, or cells, are called the *internal lobules*; by which name they are distinguished from the lesser lobes spoken of. They are separated from one another by interstices, which receive the vessels, and are filled up with membranes propagated from the lobules, and lying parallel, some angular. These lobules discover and display themselves very exactly, if the larger trunks of the bronchia be laid open, and the latter blown into by which means, every lobule belonging to that branch will be inflated, and rise very distinctly, and show its extent.

The whole substance of the *lungs* is covered with a common membrane, continued from each pleura, which is divisible into two coats; the outer thin, smooth, and nervous; the inner somewhat thicker and rougher, consisting mostly of the extremities of vessels and vesicles, through the impression of which it is pitted, and resembles, in some measure, a honeycomb. Some affirm, that in this coat are abundance of perforations, or pores, so disposed, that they resemble those any humidity from the cavity of the thorax, but suffer nothing to escape into it: but this seems little more than a fancy.

The vessels of the *lungs* are, the bronchia, the pulmonary and bronchial arteries and veins, nerves, and lymphatics. Of these vessels, some are proper, and some common, in respect of the service they are of to the rest of the body. The common are, the bronchia, the pulmonary artery and vein, the nerves and lymphatics; the proper are, the bronchial artery and vein.

Dr. Willis, contrary to the common opinion, ascribes to the *lungs* a great number of nerves, which come from the trunk of the par vagum; and which being distributed through the substance of the *lungs*, enhance the serious and sanguiferous vessels. He also asserts, that the vesicles have musculous fibres, to enable them to exert a greater contractive force in expiration; though others deny any such fibres. Diemerbroeck observes, that the vesicles admit not only of air, but also of other grosser matter; and instances two asthmatic persons which he opened; the one a shoemaker, the vesicles of whose *lungs* were so filled with dust, that, in cutting, his knife seemed as if through a heap of dusty; and the other a feather-dresser, in whom the vesicles were full of the fine dust, or down, of feathers. See ASTHMA.

From the experiments made on living animals by Dr. Hamilton, Dr. Hendley, and Mr. Brunsoil, the *lungs* seem to all independent of the thorax, continuing to be distant and contracted after they are exposed to the air. Phil. Trans. N° 441. sect. 4. Lectures on Respiration. Mem. de l'Acad. des Sciences, 1733.

An artificial inflation of the *lungs* of a dead or dying animal will put the heart in motion, and continue it so for some time. And we have an instance of the successful application of this experiment to the restoring the life of a person suffocated by the steam of a coal-pit. See Medic. Eff. Edinb. vol. v. And Phil. Trans. N° 475. sect. 11.

In the medical Tables Edinb. we read of an ulcer in the *lungs* piercing through the diaphragm into the liver. See *vol. I. art. 26.*

Dropsy of the LUNGS. See DROPSY.

Purpose of the LUNGS. See PURPOSE.

LUNGS *wounded*. There is always reason to apprehend that the *lungs* are wounded, when the patient voids a great quantity of frothy blood by the mouth, accompanied with a cough after receiving a wound in the thorax, especially when the blood that is voided at the wound is very florid, and the patient makes a particular noise when he draws his breath. The office of the surgeon, in this case, is to clear the cavity of the thorax from extravasated blood, and to heal the external wound, when that may be done with safety; but as no application can be made to the internal wound, that must be left to nature. Wherever the divided vessels contract themselves, and the blood stops of itself, the patient will recover. The persons who have recovered from these wounds, are afterwards subject to consumptions, and ulcers of the *lungs*. Sometimes, in cases of this kind, the wounded part of the *lungs* pushes itself

itſelf forward, and ſticks pretty firmly in the orifice of the external wound. In this caſe, if it is forced back again, it will diſcharge a great quantity of blood into the cavity of the thorax; therefore it is better to let it remain in the ſituation nature has thrown it into; for by this means it will admit of the immediate application of proper dreſſings, and you may ſafely encourage it to adhere to the lips of the external wound: but if a wounded portion of the *lungs* ſhould be puſhed out of the thorax, beyond the limits of the external wound, a fine piece of linen is to be wrapped round this part, and a ligature muſt be then made above the linen, and all that is below the ligature taken off with a fine knife, and the ſound part of the *lungs* muſt then be returned into the body, keeping one end of the ligature conſtantly hanging out at the external wound; the wound is then to be kept open with a tent, and the ligature at length may be ſafely drawn out. The wound is then to be healed in the ordinary way. And during the courſe of the cure the patient muſt take internally vulnerary decoctions, and Lucatellus's balſam. By this treatment, wounds of this dangerous kind are ſometimes cured; but when they are not, it is a ſatisfaction to know that all has been done, that could be done in ſo deſperate a caſe. *Heiſter's Surgery*, p. 73.

LUNGS, *Inflammation of the.* See PERIPNEUMONY.

LUNGS *of inſects.* In the fly claſs the ſtigmata are extremely numerous, and the trachęæ which they terminate are branched and divaricated all over the body in an amazing manner, as if every part and particle of the bodies of theſe little animals had occaſion for its particular air-veſſels; beſides theſe, however, flies are provided with proper *lungs*. They have two, and theſe ſo very large, that they frequently take up half, and ſometimes two thirds of the body of the animal.

Theſe are two bladders placed ſideways one by the other, alike in ſhape and ſize, and having their origin at the junction of the corcelet and body; and in many flies, whole bodies are compoſed of five rings, extending to the third, and ſometimes reaching the fourth. The ſize and figure of each of *theſe* bladders are ſuch, as is neceſſary to fill almoſt entirely that cavity of the body in which it is lodged. They each of them touch the ſides of this cavity; the part when they join one another is flat, and this commiſſure forms a fine running ſtraight down the body; they are, however, in this part, though ſo cloſely in contact, yet not at all joined to one another: this commiſſure, however, does not reach quite up to the back, or quite down to the belly, there is a ſmall *cavity* left between each, which was very neceſſary in both places; the one to give paſſage to the great *artery*, the other to the excrements. Reaumur's Hiſt. Inſ. vol. iv. p. 267. &c.

LUNGS, *Sea*, in *Zoology*. See MEDUSA.

LUNGS, *Stiefs*. See VENTILATOR.

LUNG-*wort, pulmonaria*, in *Botany*, a genus of the *pentandria monogynia* claſs. Its characters are theſe: the flower has a cylindrical, five-cornered, permanent empalement, cut into five parts at the top; the flower is of one petal, having a cylindrical tube, of the length of the empalement, cut at the top into five parts, which ſpread open, but the chaps are pervious; it has five ſhort ſtamina, terminated by erect ſummits, which cloſe together; and four germina ſupporting a ſhort ſtyle, crowned by an obtuſe indented ſtigma; the germina turn to four roundiſh ſeeds ſitting in the bottom of the empalement. There are ſix ſpecies.

The figure of the flower-cup is what principally diſtinguiſhes the *pulmonaria* from the bugloſs, *&c.* and the plants of it may be uſually known when not in flower, by their long, rough, and not divided leaves, which in almoſt all the ſpecies are ſpotted, ſo as to reſemble the tabid *lungs* of an animal, whence it had its name. Tourn. Inſt. p. 137.

The leaves of the common ſpotted *pulmonaria*, or, as we vulgarly call it, *ſage of Jeruſalem*, or Jeruſalem cowſlip, which grows wild in many parts of Europe, and flowers in our gardens in April and May, have been eſteemed an excellent medicine in many of the diſorders of the *lungs*; and have been ſaid to do great ſervice in ſpitting of blood, though Dr. Lewis ſays, that they appear to have little medicinal virtue; and they ſtand greatly recommended, externally uſed, as a conſolidator and healer of old ulcers as well as freſh wounds.

LUNG-*wort, cow's.* See MULLEIN.

LUNG-*wort, golden.* See HAREWEED.

LUNISOLAR, in *Aſtronomy and Chronology*, denotes ſomething compoſed of the revolution of the ſun, and of that of the moon.

LUNISOLAR *year* is a period of years made by multiplying the cycle of the moon, which is nineteen, by that of the ſun, which is twenty-eight; the product of which is five hundred and thirty-two; in which ſpace of time theſe two luminaries return to the ſame points.

LUNULA, in *Geometry*. See LUNE.

LUNULA, the *half moon*, among the Romans, an ornament the patricians wore on their ſhoes.

LUNULA was alſo an ornament in form of a moon, worn by the ladies.

LUNULAR *angles*. See ANGLE.

LUNULARIA, in *Botany*, a name given by Micheli to certain ſpecies of the marchantia, a kind of LICHEN. Theſe have the male cup divided into four ſegments, and thoſe tarning their edges over the flower; whereas the marchantia, as he calls them, have eight or ten ſegments, and thoſe plain.

LUNULATED *leaf*, among *Botaniſts*. See LEAF.

LUPERCALIA, feaſts inſtituted, in ancient Rome, in honour of the god Pan.

The word comes from *Lupercal*, the name of a place under the Palatine mountain, where the ſacrifices were performed.

The *Lupercalia* were celebrated on the fifteenth of the calends of March, that is on the fifteenth of February; or, as Ovid obſerves, on the third day after the ides. They are ſuppoſed to have been eſtabliſhed by Evander.

On the morning of the feaſt, the LUPERCI, or prieſts of Pan, ran naked through the ſtreets of Rome, ſtriking the married women they met on the hands and body, with a thong, or ſtrap of goat's leather; which was held an omen promiſing them fecundity and happy deliveries.

The reaſon of this indecent cuſtom, in celebrating the *Lupercalia*, took its riſe from Romulus and Remus: for while they were aſſiſting at this feaſt, a body of robbers taking hold of the occaſion, plundered them of their flocks. Upon this, the two brothers, and all the youth that were with them, throwing off their clothes, to be the more expeditc, purſued the thieves and recovered their prey. This ſucceeded ſo well, that henceforward this ceremony became a part of the *Lupercalia*.

This feaſt was abolihed in the time of Auguſtus; but it was afterwards reſtored, and continued to the time of the emperor Anaſtaſius. Baronius ſays, it was abolihed by pope Geleſius, in 496.

LUPERCI, a name given to the prieſts of the god Pan.

The *Luperci* were the moſt ancient order of prieſts in Rome: they were divided into two colleges, or companies; the one called *Fabii*, and the other *Quintilii*: to theſe Ceſar added a third, which he called *Julii*.

Suetonius mentions the inſtitution of this new college of *Luperci* as a thing that rendered Ceſar more odious than he was: however, it appears, from the ſame paſſage of Suetonius, that this new company was not inſtituted by Ceſar, nor in honour of Pan, but by ſome friends of Ceſar, and in honour of himſelf.

LUPI *crepitus*. See CREPITUS.

LUPIA, in *Surgery*, a name given by ſome authors to that ſort of ſwelling, called by others *talpa* and *aglado*. This is an encyſted tumor, more diſtinguiſhed by its ſituation than by its nature, ſince of whatever kind it be, whether inflammatous, or atheromatous, *&c.* if ſituated under the ſcalp, it is called by theſe names. Heiſter's Surgery, p. 51.

LUPINASTER, in *Botany*, the name given by Buxbaum to a new genus of plants, from their near approach to the characters of the lupine; the flowers are like thoſe of the other papilionaceous plants; the leaves are digitated as in the lupines; the flowers are collected into a head, ſuſtained on a long peticle, ariſing from the ale of the leaves: the pods are flat, and the ſeeds kidney-ſhaped; the ſtalks are ſix or eight inches high; the leaves long, or a bluiſh green, ſharply ſerrated, and elegantly ſtriated; they grow, ſix, ſeven, or eight on a peticle, which comes out of a yellowiſh membrane ſurrounding the ſtalk; the flowers are of a bluiſh purple, and ariſe out of cups, divided into ſeveral ſegments; the pods are long and depreſſed, and the ſeeds black and kidney-ſhaped. It grows in great plenty about the banks of the Volga. Act. Petrop. vol. ii. p. 340.

LUPINE, *lupinus*, in *Botany*, a genus of the *diadelphia decandria* claſs. Its characters are theſe: the empalement is biſid and of one leaf; the flower is of the butterfly kind; the ſtandard roundiſh, heart ſhaped, indented at the top, and the ſides reflexed and compreſſed; the wings are nearly oval, and cloſe at their baſe, the keel narrow, falcated, and ending in a point; it has ten ſtamina joined at their baſe in two bodies, but diſtinct above; in the center is ſituated a hairy compreſſed germen, which becomes an oblong, large, thick ſhelled pod with one cell, ending with an acute point, including ſeveral roundiſh compreſſed ſeeds. There are ſix ſpecies of this plant, propagated in gardens, where they make a very

very agreeable appearance. But the kind moſt frequent with us is the leſſer purple or blue-flowered kind. This is propagated by ſowing the ſeeds in a common flower border, where they require no care, but will come up and thrive of themſelves; they ſhould be ſown in April, in the places where they are to remain, for it gives leſs trouble, and they are plants which but very badly bear tranſplanting. This firſt flowers in June and July, and the ſeeds ripen in autumn. The common yellow *lupine* is cultivated for the ſweetneſs of its flowers, though they are of ſhort duration, eſpecially in warm weather. The ſeeds ſhould therefore be ſown at different times, viz. in April, May, and June, that there may be a ſucceſſion of flowers through the ſeaſon. If ſome of theſe ſeeds are ſown in autumn on a warm border, the plants will often live through the winter, and flower early in the ſpring. The ſeeds of the manured *lupine*, with a white flower, being of a bitter taſte, are ſometimes uſed in medicine, to open, digeſt, diſſolve and cleanſe. The flower of the ſeed has been occaſionally mixed with the juice of lemon, and a little *ſpermaceti* barbatum, and made up in the form of ſoft ointment, to make the face ſmooth Miller.

LUPULUS, *hop*, in *Botany*. See HOP.

LUPUS, *Wolf*, in *Aſtronomy*, a ſouthern conſtellation, joined to the CENTAUR, whoſe ſtars in Ptolemy's Catalogue are nineteen; in the Britannic Catalogue with Sharp's Appendix, twenty-four: the order, names, longitudes, latitudes, magnitudes, &c. are as follow:

	Magnitudes.	Longit.		Latitude		
		°	′	°	′	″
Southern in the fore foot		20	21	0	12	58	21	S.
Northern		20	36	22	11	28	12	S. 6
Preced. of the two in the noſe	5	18	10	3	14	25	44	S. 6
Second	2	18	7	2	14	34	8	S. 6
		18	29	40	13	7	48	S.

Southern of two in the throat	3	7	23	50	17	21	6	S.
Northern	4	8	44	50	15	39	0	S.

LUPUS, in *Botany*, a name ſaid to be given by Pliny to the common hop: this is however, an *error*, for though the word ſtands in moſt of the copies of that author *lupus*, the true meaning is doubtleſs *lupulus*: *the hop*. Pliny has coupled it with a word that expreſſes its climbing upon *willows*, calling it *lupus ſalictarius*. We find in all the old writers the *upulus*, which is the proper name of the hop before the initial *l* was added, joined with the word *ſalictarius*, but no where mention of *lupus ſalictarius*, unleſs in Pliny.

LUPUS, in *Ornithology*, a name given by ſome authors to the *manedula* or JACKDAW, from his voracious appetite and habit of ſtealing.

LUPUS, in *Zoology*. See WOLF.

LUPUS *aureus*, the *gilt colowred wolf*, in *Zoology*, the name by which Latin authors call the creature known in Engliſh by the name of the JACKALL.

LUPUS *cervarius*, in *Zoology*, a name by which many authors have called the LYNX, from its feeding on deer.

LUPUS *marinus*, the *ſea-wolf*, the *anarhicas lupus*, of Linnæus, in *Ichthyology*, a fierce and voracious ſea-fiſh, confined to the northern ſeas of our globe. It is found in thoſe of Greenland, Iceland, and Norway, on the coaſts of Scotland, and of Yorkſhire, and in that part of the German ocean, which waſhes the ſhores of Holland. Its head is larger in proportion to its ſize than that of the ſhark, and rounder, a little flatted on the top; the noſe blunt; the noſtrils very ſmall; the eyes ſmall, and placed near the end of the noſe; the body is long, and a little compreſſed ſideways; the back, ſides, and fins, are all of a livid lead colour; the two firſt marked downwards with irregular, obſcure duſky lines, which in different fiſh have different appearances. The youngeſt of a greateſt caſt; the belly is white; the ſkin is rough and ſoft, but his teeth ſo remarkable hard and ſtrong, that if he bites againſt an anchor of a ſhip, or other ſuch ſubſtance, he makes a loud noiſe, and leaves his marks in the iron; the fore-teeth are ſtrong, conical, diverging a little from each other, ſtand ſix out of the jaws, and are commonly ſix above and ſix below, though ſometimes there are only five in each jaw: theſe are ſupported within ſide by a row of leſſer teeth, which make the number in the upper jaw ſeventeen or eighteen, and in the lower eleven or twelve. The ſides of the lower jaw are convex inwards, and the grinding teeth of this jaw are higher on the outer than the inner edges, and join to the canine teeth, but in the upper are ſeparated from them; in the centre are two rows of flat ſtrong teeth, fixed on an oblong baſis upon the bones of the palate and noſe: theſe and the other grinding teeth are often found foſſil, and called BUFONITES, or toad-ſtones. The two bones that form the under jaw are united before by a looſe cartilage, ſerving by a free motion to the purpoſe of breaking, grinding, and comminuting its teſtaceous and cruſtaceous food, as crabs, lobſters, prawns, muſcles, &c. At the entrance of the gullet, above and below, are two very ſmall echinated bones. It has two fins like wings, ſituated juſt under the gills; and one long ſtarſ fin running from the head to the tail, and another reaching from the anus to the tail; the tail is round at its end, and conſiſts of thirteen rays. This fiſh grows to a large ſize, being ſometimes found on the Yorkſhire coaſt of the length of four feet, and near Shetland more than ſeven feet. Pennant. *See Tab.* III. *Fiſh*, N° 22.

To LURCH, in *Fencing*, is to make an opening in order to invite your adverſary to thruſt at you, when you, being ready, may find a favourable repoſt at him.

LURCHER, among *Sportſmen*, a kind of hunting DOG, like a mongrel greyhound, with pricked ears, a thaggy coat, and generally of a yellowiſh-white colour.

LURE, in *Falconry*, a piece of red leather cut in form of a bird, with two wings, ſtuck with feathers; and ſometimes baited with a piece of fleſh: wherewith to reclaim, or call back a hawk.

The word comes from the French *leurre*, which ſignifies the ſame; formed, according to Skinner, from the Anglo-Saxon, *luren*, *irritare*; or, according to Triſanet, from *leura*, *craftineſs*. *See* FALCON and HAWKING.

LUSCINIA, the *nightingale*. See NIGHTINGALE.

LUSHBURGHS, or LUXENBURGHS, in our *Old Writers*, a baſe ſort of foreign coin, made of the likeneſs of Engliſh money, and brought into England in the time of Edw. III. to deceive the king and his people: on account of which it was made treaſon, for any one willingly to bring any ſuch money into the realm, as knowing it to be falſe. Stat. 25 Edw. III. 3 Inſt. 14.

LUSITANICA *rubra bolus*, is an impure earth, of a florid red colour, compact texture, and heavy: it colours the hands, and is very friable, readily diſſoluble in water, and raiſes with it a ſtrong ebullition: it melts readily in the mouth, has a ſtrong aſtringent taſte, is gritty, and adheres firmly to the tongue. It acquires hardneſs and a brighter colour by burning; it is of an alkaline quality: it is dug in the kingdoms of Portugal and Spain; it is alſo found near the Havannah and La Vera Cruz in New Spain. It is eſteemed a very valuable aſtringent, and an effectual remedy for fluxes and other diſtempers of that kind. It is alſo accounted alexipharmic by the Spaniards and Portugueſe. They make an earthen ware of this *bole*, which they call *bucaros*: the ware is of a fine red colour, ſmooth and poliſhed, though it is merely dried and not glazed. They uſe it to filtre, cleanſe, and cool the water. Veſſels of the ſame kind are alſo brought from the Havannah and Vera Cruz.

LUST, at *Sea*. If a ſhip *heel* either to ſtar-board or port, the ſeamen ſay ſhe hath a *luſt* that way; and they ſay ſo though it be occaſioned only by the ſhooting of her ballaſt, or by the unequal flowing of things in her hold; though it is more properly ſaid of a ſhip, when ſhe is inclined to heel any way upon account of her mold or make.

LUST-*gyrt*, in *Botany*. See STRAMONIUM.

LUSTER, or LUSTRE, gloſs, or brightneſs appearing on any thing; particularly on manufactures of ſilk, wool, or fluff.

LUSTRE is alſo uſed for a certain compoſition, or manner of giving that gloſs or brilliance.

The *luſtre* of ſilks, in which their chief beauty conſiſts, is given them by waſhing in ſoap, then clear water, and dipping them in alum-water cold.

The *luſtre* of black taffety is given by double-brewed beer, boiled with orange or lemon-juice; that of colored taffeties

taffeties with water of gourds, diſtilled in an alembic. Curriers give a *luſtre*, or gloſs to the leather ſeveral ways, according to the colour it is to be illuſtrated. For blacks, the firſt *luſtre* is with juice of barberries; the ſecond with gum arabic, alc. vinegar, and Flanders glue boiled together; for coloured leathers, they uſe the white of an egg beaten in water: Morocens have their *luſtre* from juice of lemon, and lemon or orange.

For teſts, *the aqua fortis* frequently given with common water; ſometimes a little black dye is added. The ſame *luſtre* ſerves ſkinners, except that as whites furs they never uſe any black dye. For very black furs, the Mooremans prepare a *luſtre* of galls, copperas, Roman alum, ſublimate, and other ingredients.

The *luſtre* given to clocks and mohairs, by PASSING them under the CALENDER.

LUSTRE, an appellation given to a branched candleſtick, when made of glaſs. See BRANCH and JESSE.

LUSTRAL, an epithet given by the ancients, to the water uſed in their ceremonies, to ſprinkle and purify the people. From them the Romaniſts have borrowed the holy water uſed in their churches.

LUSTRALIA, *dies* LUSTRALES, that wherein the luſtrations were performed for a child, and its name given; which was uſually the ninth day from the birth of a boy, and the eighth from that of a girl. Though others performed the ceremony on the laſt day of that week wherein the child was born, and others on the fifth day from its birth.

Over this feaſt-day the goddeſs Nundina was ſuppoſed to preſide; the midwives, nurſes, and domeſtics, handed the child backwards and forwards, around a fire burning on the altars of the gods, after which they ſprinkled it with water; hence this feaſt had the name of AMPHIDROMIA. The old women mixed ſalt and daſt with the water. The whole ended with a ſumptuous entertainment. The parents received gifts from their friends on this occaſion. If this child was a male, their door was decked with an olive-garland; if a female, with wool, denoting the work about which women were to be employed. Potter.

LUSTRATION, *expiation*, in antiquity, ſacrifices, or ceremonies, by which the Romans purified their cities, fields, armies, or people defiled by any crime, or impurity.

Some of the *luſtrations* were public, others private.

There were three ſpecies or manners of performing *luſtrations*; viz. by fire and ſulphur; by water; and by air: which laſt was done by fanning and agitating the air round the thing to be purified.

There was alſo a peculiar kind of *luſtration* for young children.

Lampridius has a volume expreſs on the *luſtrations* of the auctions; viz. Lampridii Cantianenſis Epimenedes, ſive de veterum gentilium *Luſtrationibus*; firſt printed at Utrecht in 1661, and ſince, with additions, in 1702, 4to.

All perſons, ſaints only excepted, he ſhews, were miniſters of ſome ſort of *luſtration*. When any one died, the houſe was to be ſwept after a particular manner, by way of purification; the prieſt threw water on new married people, with the like intention. To purify themſelves, people would even ſometimes run naked through the ſtreets; ſuch was their extravagance. And, as if ſuperſtition enough in inventing modes of *luſtration*, they even uſed enchantments to raiſe the dead, in order to receive inſtructions what they muſt do to purge themſelves of their crime. Add, that they frequently raiſed the opinion of the efficacy of their expiations by fictitious miracles.

It was common, on theſe occaſions to ſhed human blood: the prieſts of Cybele, Bellona, and Baal, made cruel inciſions on themſelves. Euetheus, king of Attica, ſacrificed his daughter to Proſerpina. Several had their throats cut at Rome, to obtain the emperor's health from the gods. Thoſe who commanded armies, offered one of their ſoldiers to appeaſe the anger of the gods; that he alone might ſuffer all the wrath the army deſerved.

All ſorts of perfumes, and odoriferous herbs, had place in *luſtrations*. The egg was much uſed among them, as being the ſymbol of the four elements: its ſhell, they ſay, repreſents the earth; the yolk, a globe of fire; the white, reſembles the water; and beſides it has a ſpirit, they ſay, which repreſents the air. For this reaſon it is, that the Romans, or Indian prieſts, believe to this day that the world came out of an egg. There is ſcarce any perſon, public, true, or mythic, which they did not offer to, in their lu ſ ſ rations: nor did they forget milk, honey, wine, or honey: what is more, they made uſe of the very ſpittle, and urine.

The pagan prieſts believed that the gods purified themſelves; and when they wanted to purify their ſtatues. They made a *luſtration* for children, the eighth day after their birth. When a man who had been falſely reputed dead, returned home, he was not to enter his houſe by the door. It was a ſettled cuſtom to offer no expiation for thoſe who were hanged by order of juſtice; or that were killed by thunder. Neither did they offer any for thoſe who were drowned in the ſea: it being the common opinion, that their ſouls periſhed with their bodies. And hence it was, that perſons in danger of ſhipwreck, ſometimes thruſt their wounds through their bodies, that they might not die in the ſea; where they thought their ſoul, which they ſuppoſed to be a ſtame, would be totally extinguiſhed.

The moſt celebrated expiatory ſacrifice was the hecatomb, when they offered a hundred beaſts; though they commonly did not offer ſo many, but contented themſelves with killing twenty-five; but thoſe being quadrupeds, their feet alone were hundred.

The manner of the Macedonians purifying their army by *luſtration* was thus: at the time of their feſtival Xanthica, they divided a bitch into two halves, one of which, together with the entrails, was placed upon the right hand, the other upon the left; between theſe the army marched in this order: after the arms of the Macedonian kings, came the firſt line of the army, conſiſting of horſe; theſe were followed by the king, and his children, after whom went the life guards; then followed the reſt of the army: this done, the army was divided into two parts, one of which being fet in array againſt the other, there followed a ſham encounter, in imitation of a fight. Potter, Archæol. Græc. lib. ii. c. 20. tom. i. p. 417.

Luſtrations, and luſtrare ſacrifices, were not only performed for men, but alſo for temples, altars, theatres, trees, fountains, rivers, ſheep, fields, and villages. When the Arval brothers offered a victim for the fields, their ſacrifice was called *ambarvalia*.

Cities were all to be purified, from time to time: ſome made the victim walk round their walls, and then ſlew him. The Athenians ſacrificed two men, one for the men of their city, and the other for the women. The Corinthians ſacrificed the children of Medea to; though the poets ſay, Medea killed them herſelf. The Romans performed the ceremony of purifying their city every lifth year; whence the name of *luſtrum* was given to the ſpace of five years.

Divers of the explations were auſtere: ſome faſtful; others abſtained from all ſenſual pleaſures; ſome, as the prieſts of Cybele, caſtrated themſelves; others, that they might live chaſte, cut off, or lay under the branches of a tree called AGNUS CASTUS.

They caſt into the river, or at leaſt out of the city, the animals or other things that had ſerved for a *luſtration*, or ſacrifice of amendment; and thought themſelves threatened with ſome great misfortune, when by chance they trod upon them. At Marſeilles, they took care to feed a poor man for ſome time; after which, they charged him with all the ſins of the country, and drove him away: thoſe of Leucadia faſtened a number of birds to a man charged with their ſins, and in that condition caſt him headlong from a high tower; and if the birds hindered his being killed, they drove him out of the country.

Some of theſe ceremonies were abolithed by the emperor Conſtantine, and his ſucceſſors; the reſt fulfilled till the Gothic kings were maſters of Rome, under whom they expired; except that ſeveral of them were adopted by the popes, and brought into the church, where they make a figure to this day: witneſs the numerous conſecrations, benedictions, exorciſms, ablutions, ſprinklings, proceſſions, feaſts, &c. ſtill in uſe in the Romiſh church.

LUSTRINGS. A company was incorporated for making, dreſſing, and luſtring alamodes and *luſtrings* in England, who were to have the ſole benefit thereof, by ſtat. 4 and 5 W. and M. And no foreign ſilks known by the name of *luſtrings* or alamodes are to be imported, but at the Port of London, &c. Stat. 9 and 10 W. III. c. 43. See SILK.

LUSTRUM, a term uſed by the Romans, to ſignify a ſpace of five years.

Varro derives the word from *lus*, *to waſh*, becauſe at the beginning of every fifth year, they paid the cenſus, or tribute impoſed by the cenſors; whoſe authority, at their firſt inſtitution, was confined them for five years; though afterwards it was abridged to one. Others rather derive the word from *luſtrare*, *to make a review*; becauſe once in five years the cenſors reviewed the army.

LUSTRUM was alſo a ceremony, or ſacrifice uſed by the Romans, after numbering their people, once in five years. See LUSTRATION.

The *lustrum* was accompanied always by a *luſtration* of the people, by the word *luſtrum*, has conſtantly been taken by the ancients and moderns for a term of five years: yet, if we enquire into the real ſtate of the caſe, we ſhall find no good ground for fixing to preciſe a ſignification

to it; but, on the contrary, that the CENSUS and *lustrum* were, for the moſt part, held irregularly and uncertainly, at very different and various intervals of time, as the particular exigencies of the ſtate required. Middlet. of Rom. Sen. p. 167.

LUTATION, in *Chemiſtry*, is uſed for the cementing of chemical veſſels cloſe together.

LUTE, LUTUM, in *Chemiſtry*, a compoſition of certain tenacious ſubſtances, wherewith to cloſe the apertures and junctures of veſſels in diſtillation, &c.

Under *lute* is comprehended any ſort of cement, or plaſter, uſed either in the conſtruction of furnaces, or in fitting to them veſſels of glaſs or earth, that are to reſiſt a very violent fire. Some *lutes* are made of flour and water; others, of quick-lime and whites of eggs; others, of iron-filings, brick-duſt, and linſeed oil; others, of potters earth, river-ſand, horſe-dung, powder of broken pots, caput mortuum of vitriol, droſs of iron, beaten glaſs, flocks of wool mixed with ſalt water or bullock's blood. The *lute* uſed by Lemery was only two parts of ſand, and one of clay, tempered together in water; which does very well for joining the noſes of retorts and their receivers in diſtilling of volatile ſpirits, &c.

Others have recommended for covering the inſide of FURNACES, a maſs of clay mixed with ſand, and moiſtened with three or four times as much ox blood diluted with water. The beſt lute, and eaſieſt to be had at London, is a ſort of clay called Windſor loam, which muſt be mixt pretty ſtiff, and preſſed into the inſide of the furnace, firſt wetted with water; and when the clay begins to dry, it muſt be beat down cloſe to the ſides with a wooden mallet; then the unevenneſs and cracks filled up with freſh clay ſomewhat moiſter, ſo as to be made ſmooth and even with a trowel, and then left to dry gently; and if any cracks happen, they muſt again be filled up.

Dr. Shaw recommends the following mixture: take a buſhel of Windſor loam, four quarts of brick-duſt, two quarts of powdered green glaſs, two quarts of iron filings, four handfuls of cow-hair, and eight handfuls of horſe-dung; beat theſe all together, and add a ſufficient quantity of bullock's blood to make a ſtiff and uniform paſte. In diſtilling by the alembic, or veſica, or copper body, with its head or ſerpentine, a wet bladder ſerves very well to *lute* the junctures of the veſſels; ſlips of paper or linen, covered with flour paſte, will alſo anſwer this purpoſe: which more penetrating and diſſolving vapours are contained in the veſſels, it will be neceſſary to uſe a *lute* formed of quick-lime ſlaked in the air, and beat into a liquid paſte, with whites of eggs, which ſhould be ſpread upon ſlips of linen, and applied exactly to the juncture of the veſſels: but for the diſtillation of corroſive ſpirits, as alſo to ſtop the cracks of glaſſes, &c. the following compoſition is recommended; viz. ſtarch boiled, or iſinglaſs diſſolved in ſpirit of wine, with flour of ſulphur, maſtic, and lime ſlaked with milk.

For this purpoſe recourſe muſt be had to what is called the fat *lute*; made by forming into a paſte ſome dried clay finely powdered, ſifted through a ſilken ſcarce, and moiſtened with water, and then by beating this paſte in a mortar, with boiled linſeed oil, that is oil which has been rendered drying by litharge diſſolved in it, and fit for the uſe of painters. This *lute* may be made up in a cylindric form, and ſhould be applied by flattening it to the joinings of the veſſels, previouſly well dried, and the whole covered with ſlips of linen, ſpread with *lute* of lime and whites of eggs: theſe ſlips muſt be faſtened with packthread. See CEMENT and MORTAR.

LUTE, a muſical inſtrument of the ſtring kind; which had anciently but five rows of ſtrings; though in courſe of time, four, five, or ſix more have been added.

Some derive the word from the German *laute*, which ſignifies the ſame; or from *lauten*, *ſonare*. Scaliger and Bochart derive it from the Arabic, *alland*.

The *lute* conſiſts of four principal parts: the table, the body or belly, which has nine or ten ſides; the neck, which has nine or ten ſtops or diviſions, marked with ſtrings; and the head or croſs, wherein are ſcrews, for raiſing or lowering the ſtrings to the proper tone. In the middle of the table is a roſe, or paſſage for the ſound. There is alſo a bridge that the ſtrings are faſtened to, and a piece of ivory between the head and the neck, to which the other extremity of the ſtrings is fitted. In playing, the ſtrings are ſtruck with the right hand, and with the left the ſtops are preſſed.

The *lutes* of Bologna are eſteemed the beſt; on account of the wood, which is ſaid to have an uncommon diſpoſition for producing a ſweet ſound. The theorbo is an improvement on the common *lute*.

LUTE, *temperament of the*, denotes the alteration requiſite to be made in the intervals, both with regard to concords, and diſcords, in order to render them more juſt on that inſtrument.

LUTE, *archi*. See ARCHLUTE.

LUTE, *theorbo*. See THEORBO.

LUTEA, in *Natural Hiſtory*, the name of a ſpecies of fly found frequently near waters after rain; it is of a dunniſh yellow colour, the wings are long, and the eyes large and prominent; the tail is thick, and has two hairy of a conſiderable length, growing at the head, ſo that it is of the briſtle kind.

LUTEA is alſo a name by which ſome authors have called the YELLOW *hammer*.

LUTEOLA, in *Botany*. See DYER'S *weed*.

LUTIOLA, in *Zoology*, a name given by many to a ſmall bird, called by others *viſtor*, and by others *regulus non criſtatus*; but this laſt is a name that has occaſioned ſome confuſion, as many have erroneouſly called our common wren the *regulus*, and as it has no creſt, imagined it to be the bird meant by this name.

It is, excepting the creſted wren, the ſmalleſt of all European birds, and it very little exceeds that in ſize; its head, neck, and back are of a greeniſh brown; the rump is greener than the reſt; it has a yellow line on each ſide, extended from the noſtrils, beyond the eyes, to the hinder part of the head; the breaſt, throat, and belly, are yellow, with a very faint caſt of green; the wings and tail are brown, and all their feathers are tipped with green at their ends; the under part of the wings has much of a very fine green; the beak is extremely ſlender and half an inch long; the mouth is yellow within; it makes a loud noiſe, like that of a graſshopper, and is principally found among willows; it is continually creeping and ſinging among the branches of trees; it builds with ſtraw and feathers, and lays five eggs, which are white, and ſpotted with red: there is a conſiderable variation in the colours of theſe birds; ſome of them being much greener on the back, and much whiter on the belly, than others.

LUTHERANISM, in *Eccleſiaſtical Hiſtory*, the ſentiments of Dr. Martin Luther, and his followers, with regard to religion.

Lutheraniſm had its riſe in the 16th century: its author was born at Iſleben in Thuringia, in 1483. After his ſtudies he entered himſelf among the Auguſtines, and having found a copy of the Bible, which lay neglected in the library of his monaſtery, he devoted himſelf with ſurpriſing aſſiduity to the ſtudy of the ſcriptures; and in 1512, took the cap of a doctor in theology, in the univerſity of Wittemberg. In 1516, he attacked the ſchool divinity in ſeveral theſes. In 1517, Leo X. ordered indulgences to be diſpenſed to thoſe who ſhould contribute towards the building of St. Peter's church at Rome, comprehending all ſins paſt, preſent, and future. Albert, archbiſhop of Mentz and Magdeburgh, appointed John Tetzel, a monk of the Dominican order, notorious for his profligacy, barbarity, and extortion, to preach and proclaim theſe indulgences in Germany. The inſolence and indecency with which Tetzel executed his commiſſion, rouſed the indignation of Luther, who, in ninety-five propoſitions, maintained publicly at Wittenberg, on the 30th of September, 1517, cenſured the extravagant extortion of theſe queſtors, and plainly pointed out the Roman pontiff as a partaker of their guilt; ſince he ſuffered the people to be ſeduced by ſuch deluſions from placing their principal confidence in Chriſt, the only proper object of their truſt.

He alſo wrote to Albert, warmly remonſtrating againſt the falſe opinions and wicked lives of the preachers of indulgences; and in order to gain the ſuffrage of men of learning, he publiſhed his ninety-five theſes; appointing a day, on which the learned were invited to impugn them either in perſon, or by writing, and ſubjoining to the whole, ſolemn proteſtations of his high reſpect for the apoſtolic ſee, and of his implicit ſubmiſſion to its authority. No opponent appeared at the time appointed; the theſes ſpread over Germany with aſtoniſhing rapidity; they were much read and approved: at the ſame time the boldneſs and novelty of his opinions, drew great attention from his hearers, and being recommended by the authority of Luther's perſonal character, and by a popular and perſuaſive eloquence, made a deep impreſſion. Luther was alſo an Auguſtinian, and Tetzel a Dominican; and, therefore, he was more encouraged than oppoſed by the friars of his own order, who hoped to ſee the Dominicans expoſed to the hatred and ſcorn of the people. He was alſo ſecretly ſupported by his ſovereign, the elector of Saxony, who, without to ſee the exactions of the court of Rome reſtrained. This was the commencement and foundation of that memorable rupture and revolution in the church, which humbled the grandeur of the ſordid pontiffs, and eclipſed ſo great a part of their glory. See REFORMATION.

It has been ſaid indeed by F. Paul, in his Hiſtory of the Council of Trent, p. 5. and after him by Mr. Hume, in his Hiſtory of England, vol. i. p. 119. as well as by others, that the Auſtin friars had been uſually employed in preaching

preaching indulgences in Saxony; but that Arcemboldo, a Genoese merchant, who was employed by Magdalen, the sister of Leo, to whom he had granted the profits arising from the sale of indulgences in Saxony, to collect the money that should be raised, and his deputies, hoping to gain more by committing this trust to the Dominicans, had bargained with Tetzel; and that Luther was prompted at first to oppose Tetzel and his associates, and to deny indulgences, by a desire of taking revenge for this injury offered to his order. Mr. Chambers, in the former edition of this work, followed the Diction. de Trevoux, as that Dictionary seems to have adopted the representation of Bossuet; and, more lately, the editors of the Encyclopedie have stated the first rise of *Lutheranism* in a manner that favours the opinion just mentioned: it is proper, therefore, to observe, that the profits arising from indulgences in Saxony and the adjacent countries, were granted, not to Magdalen the sister of Leo, but to Albert, archbishop of Mentz, who had the sole right of nominating those who published them: moreover, Arcemboldo never had any concern in the publication of indulgences in Saxony; because his district was Flanders and the Upper and Lower Rhine. Besides, the publication of indulgences in Germany was not usually committed to the Augustinians: from the year 1220, that lucrative commission was principally intrusted with the Dominicans; and they had been employed in the same office a short time before the present period: the promulgation of them, at three different periods under Julius II. was granted to the Franciscans, and the guardian of the Franciscans was joined in the trust with Albert on this occasion, though he refused to accept it: and it is remarkable, that for half a century before Luther, viz. from 1450 to 1517, the name of an Austin friar employed in this service, occurs but once. To these facts it may be added, that it is far from being probable, that Luther would have been solicitous about obtaining for himself or his order, a commission of this kind, at a time when the preaching of indulgences was become very unpopular; insomuch that all the princes of Europe, and many bishops, as well as other learned men, abhorred the traffic; and even the Franciscans and Dominicans, towards the conclusion of the fifteenth century, opposed it publicly, both in their discourses and writings: nor was this commission given to the Dominicans in general, but solely to Tetzel. Finally, Luther was never accused of opposing the publication of indulgences from resentment or envy, either in the edicts of the pontifs of his time, or in the reproaches of his contemporary writers, who defended the cause of Rome, from the year 1517 to 1546, and who were far from being sparing of their invectives and calumnies. The reader may find this matter fully stated by Dr. Maclean, the translator of Mosheim's Ecclesiastical History, in vol. iii. p. 304. note (p) 8vo. ed. and by Dr. Robertson in his Hist. of Ch. V. vol. ii. p. 125. note * 8vo edit.

But to return from a digression, which, it is hoped, will not be unacceptable to the readers of a work of this kind: the sentiments of Luther were received with applause by the greatest part of Germany; and the alarm of controversy being sounded, Tetzel published counter-theses in opposition to those of Luther, and was supported by Prierio, Eckius and others. Leo, however, treated the dispute at first with indifference and contempt; till being roused by Luther's adversaries, he summoned him to appear at Rome: but partly by Luther's own application to the pontif, and partly by the interference of Frederick the Wise, elector of Saxony, cardinal Cajetan, a Dominican, the pope's legate in Germany, was appointed to hear and determine the cause. The cardinal in an arrogant and overbearing manner insisted on Luther's renouncing his opinions, and submitting respectfully to the judgment of the Roman pontif. The intrepid reformer was not to be awed into compliance; and leaving Augsburgh, the place of conference, returned into his own country. But before his departure, he prepared a solemn appeal from the pope, ill-informed at that time concerning his cause, to the pope, when he should receive more full information concerning it. Leo, enraged at the obstinacy of Luther, published an edict in 1518, commanding his spiritual subjects to acknowledge his power of delivering from all the punishments due to sin and transgression of every kind: upon this measure, Luther appealed from the pontif to a general council. The pope, repenting of his precipitance, and desirous of bringing the dispute to an amicable conclusion, employed Miltitz, a Saxon knight, to negociate with Luther: but, though there seemed at first to be some hopes of a reconciliation, the violence of the enemies of Luther blasted these agreeable expectations, and kindled anew the flames of discord. At length Leo X. issued out a bull against Luther, dated the 15th of June, 1520, condemning forty-one heretical propositions selected from his writings, ordering his works to be burnt, and prohibiting their being read; and summoning Luther himself, on pain of excommunication, to acknowledge and retract his errors. In consequence of this rash and furious sentence, Luther withdrew himself in the most public manner from the communion of the church of Rome; committing to the flames at Wittemberg, before a vast multitude of spectators, the pope's bull of excommunication, and all the decretals and canons relating to the pope's supreme jurisdiction. Soon after this a second bull was issued against him on the 6th of January, 1521, by which he was expelled from the communion of the church, for having insulted the majesty and disowned the supremacy of the Roman pontif. These violent measures led this bold reformer to form the project of founding a church, upon principles entirely opposite to those of Rome, and to establish in it a system of doctrine and ecclesiastical discipline, agreeable to the spirit and precepts of the gospel of truth: in this noble undertaking he was encouraged by many learned and pious men in various parts of Europe, and especially by the celebrated Melancthon. In 1521, Charles V. summoned Luther to appear before the diet at Worms, where he behaved with great decency and equal firmness; he acknowledged an excess of vehemence and acrimony in his controversial writings, but refused to retract his opinions, unless he were convinced of their falsehood, or to consent to their being tried by any other rule than the word of God. However, after his departure, when it was found that neither intreaties nor threats could be of any avail, he was condemned by the unanimous suffrages both of the emperor and the princes, and declared an enemy to the whole Roman empire. Frederic, the elector of Saxony, contrived to preserve him from the violence of his enemies, by seizing him on his return, and carrying him to the castle of Wartburgh, as a place of safety: in this retreat, which he called his Patmos, Luther was concealed for the space of ten months, where he employed himself in preparing several useful compositions. During his confinement his opinions gained ground; and the Augustinians of Wittemberg, with the approbation of the university and the connivance of the elector, abolished the celebration of private masses, and gave the cup as well as the bread to the laity, in the administration of the Lord's supper. Nevertheless, at this time, his opinions were solemnly condemned by a decree of the university of Paris, and in a Treatise on the seven Sacraments, published by Henry VIII. of England. Luther soon published his animadversions both on the decree of the university and the work of the English monarch. In the month of March, 1522, he quitted his retreat, and returned to Wittemberg, in order to check the furious zeal of Carolostadt and his fanatical followers, who had begun to excite tumults in Saxony; and his appearance alone suppressed that spirit of extravagance which began to seize his party. Whilst Luther was in confinement, he had begun to translate the Bible into the German tongue, and in 1524, by his own diligent application, and the assistance of Melancthon and several other of his disciples, he finished part of the New Testament; and the publication of it proved more fatal to the church of Rome than that of all his own works. The advocates for reformation in the other countries of Europe, were thus encouraged to publish versions of the scriptures in their own languages: and several cities and princes of Germany embraced the reformed religion, and patronized Luther's opinions: and though the succeeding popes Adrian VI. and Clement VII. exerted their utmost efforts to prevent their spread, they proved altogether ineffectual. In a word the character of the man, the strength of his arguments, and the weakness of his adversaries cause, procured him an increasing number of followers. And thus it was that *Lutheranism* was formed; the adherents whereto were called *Lutherans*, from *Luther*, a name which has a Greek turn, and which he assumed in lieu of his family name, *Lother*, or *Lauther*; it being the custom of those days, for men of learning to give themselves Greek names; witness Erasmus, Melancthon, Bucer, &c.

In 1523, Luther quitted the habit of a religious, and in 1526, married Catharine a Boria, a nun of a noble family, who, having thrown off the veil, had fled from the cloister; and after having been an happy instrument of reforming a great part of Germany, under the protection of Frederick and John, electors of Saxony, he died at his native place, in 1546.

For a full and accurate account of the rise and progress of *Lutheranism*, the reader may consult Mosheim and Robertson, ubi supra. See PROTESTANTS and REFORMATION.

Lutheranism has undergone some alterations since the time of its founder. Luther rejected the epistle of St. James, as inconsistent with the doctrine of St. Paul, in relation to justification; he also set aside the Apocalypse; both

both which are now received as canonical in the Lutheran church.

Luther reduced the number of sacraments to two, viz. baptism, and the eucharist; but he believed the impanation, or CONSUBSTANTIATION: that is, that the matter of the bread and wine remain with the body and blood of Christ; and it is in this article, that the main difference between the Lutheran and English churches consists.

Luther maintained the mass to be no sacrifice; he exploded the adoration of the host, auricular confession, meritorious works, indulgences, purgatory, the worship of images, &c. which had been introduced in the corrupt times of the Romish church. He also opposed the doctrine of free-will; maintained predestination; asserted that we are necessitated in all we do; that all our actions done in a state of sin, and even the virtues themselves of heathens, are crimes; that we are only justified by the imputation of the merits and satisfaction of Christ. He also opposed the failings in the Romish church, monastical vows, the celibacy of the clergy, &c.

Some authors reckon thirty-nine different sects, which at different times have sprung up among the Lutherans.

LUTHERANS, a sect of Protestants who profess Lutheranism, or adhere to the doctrine and tenets of Luther.

The *Lutherans*, of all Protestants, are those who differ least from the Romish church; as they affirm, that the body and blood of Christ are materially present in the sacrament of the Lord's Supper, though in an incomprehensible manner; and likewise represent some religious rites and institutions, as the use of images in churches, the distinguishing vestments of the clergy, the private confession of sins, the use of wafers in the administration of the Lord's Supper, the form of exorcism in the celebration of baptism, and other ceremonies of the like nature, as tolerable, and some of them as useful. The *Lutherans* maintain, with regard to the divine decrees, that they respect the salvation or misery of men, in consequence of a previous knowledge of their sentiments and characters, and not as free and unconditional, and as founded on the mere will of God. Towards the close of the last century, the *Lutherans* began to entertain a greater liberality of sentiment than they had before adopted; though in many places they persevered longer in severe and despotic principles, than other protestant churches.

Their public teachers now enjoy an unbounded liberty of dissenting from the decisions of those symbols or creeds, which were once deemed almost infallible rules of faith and practice, and of declaring their dissent in the manner they judge the most expedient. Mosheim attributes this change in their sentiments to the maxim, which they generally adopted, that Christians were accountable to God alone for their religious opinions; and that no individual could be justly punished by the magistrate for his erroneous opinions, while he conducted himself like a virtuous and obedient subject, and made no attempts to disturb the peace and order of civil society. Eccl. Hist. vol. iv. p. 440. Brog. ed. 8vo.

LUTHERN, from the French *lucarne*, of the Latin *lucerna*, *light*, or *lucerna*, a kind of window over the cornice, in the roof of a building; standing perpendicularly over the naked of the wall; and serving to illuminate the upper story.

The French architects distinguish these into various kinds, according to their various forms; as *fouare*, *fenestre-vulat*, *bulle eye*, *flat arches*, *Flemish lutherns*, &c.

LUTRA, in *Zoology*. See OTTER.

LUTUM, in *Botany*, a name given by the ancient Roman authors to a plant since called *lutcola*, or DYER's *weed*, and by authors of later date *carduus*, and *cnicus*. It is used at this time to dye things yellow, and was so by the ancient Greeks, who expressly mention the dying woollen cloth with it. The Roman courtezans had also a way of dying their hair yellow with it.

LUTUM *sapientiæ* is the hermetical seal; made by melting the end of a glass vessel by a lamp, and twisting it up with a pair of pincers.

LUXATION, LUXATIO, formed from *luxare*, to *loose*, in *Medicine* and *Surgery*, the slipping of the head of a bone from its proper receptacle into another place, whereby the natural motion of the joint is destroyed.

Luxation is the same with what is otherwise called DISLOCATION; being the displacing of a bone, or rather the disjoining of two bones, articulated together for the motion of the part.

Luxations are either violent, proceeding from some external cause; as falls, strains, blows, leaps, extensions, &c. Or *lento*, arising from internal causes; as a natural laxity of the ligaments, a fluxion of humours, or gradual collection thereof between the joints, &c.

Luxation, properly, has place only amongst bones whose figure determines them to a manifest motion: such are all those united by DIARTHROSIS: those articulated by SYNARTHROSIS, where there is no manifest motion, are indeed subject to fracture, caries, exostosis, &c. but not to *luxation*.

Luxations, again, are either *perfect*, or *imperfect*.

LUXATION, *perfect*, or *complete*, *ἀπαρθρημα*, is that where the head of a bone is actually started out of the cavity of another. This is known by a tumor or protuberance, formed by the head of the separate bone, which raises up the skin and muscular flesh above its natural level in the part not destined to receive it; and an hollowness or sinking in the place from whence it is started, perceivable by the touch. It is also attended with great pain, a total abolition of motion, and a shortening of the limb.

LUXATION, *imperfect*, or *partial*, *παραρθρημα*, called also *subluxation*, is where the motion is only much impaired, the joint weakened, and a deformity perceivable in it, when compared with the opposite part, which is found. This is otherwise called a *strain*, when it proceeds from an external cause; or, simply, a *relaxation*, when from an internal one.

A *luxation* is said to be *simple*, when it has no other accident or injury accompanying it—*complicated*, when it is attended with a wound, inflammation, fracture, or the like.

The cure of a *luxation* is by a speedy reduction of the dislocated member to its natural place. To this are necessary:

1. *Extension*, which a luxated as well as fractured member requires; as well on account of the contraction of the tendons, as that the head of the bone may more directly be intruded into its seat. This extension is made either by the hands alone, which is called *manus postatrices*, because, among wrestlers, dislocated members used to be reduced after this manner; or by ligatures or towels; or by instruments, or great machines, when the *luxation* is difficult and inveterate.

2. After extension follows the intruding of the joint into the natural cavity; which, likewise, may either be effected by the hands only, or by the heel (as when the head of the os humeri is fallen into the arm-pit), or by means of ladders, doors, pestles, or Hippocrates's instruments, called *ambe*. This way is termed *methodical*, by way of distinction from the third, which is called *organical*, because performed by large instruments, and machines, but now altogether out of use. Gourmelinus to these adds *ἀπόθεσιν*, the very act of reducing the member into its own place, which is to be known by the sound usually heard, and from the use and motion of the reduced joint. Lastly, because, on account of the laxity of the tendons, &c. the reduced bone cannot remain in its natural position, it is necessary yet farther to apply compresses and bandage; by whose means the articulation is preserved safe till the ligaments may acquire their usual strength of elasticity and attraction.

A recent *luxation* or dislocation may generally be reduced by extention alone, which must always be greater or less, according to the strength of the muscles which move the joint, the use, robustness, and other circumstances of the patient. When the bone has been out of its place for any considerable time, and a swelling or inflammation has come on, it will be necessary to bleed the patient, and, after fomenting the part, to apply soft poultices with vinegar to it for some time before the reduction be attempted. After the reduction, it is only necessary to apply cloths dipped in vinegar, or camphorated spirits of wine to the part, and to keep it perfectly easy.

LUXATION *of the ancle, clavicle, os coxendix, cubitus, fibula, fingers, hand, humerus, jaw, knee, neck, nose, os calcis, rib, thigh, and vertebræ*. See ANCLE, CLAVICLE, *&c.*

LUXURY, denotes an addictedness to sensual pleasure. Excess of diet, which is one species of *luxury*, is prohibited by an Edw. III. stat. 3. which ordains that no man shall be served at dinner or supper with more than two courses; except upon some great holidays there specified, in which he may be served with three.

LUZZO *marino*, in *Ichthyology*, a name given by the Italians to the fish called by the ancient Greek writers, and many of the modern Latin authors, SPHYRÆNA; and by Pliny, Varro, and some other of the old Roman authors, SUDIS. Gaza has called it the *malleolus*, and the French, at this time, call it *bet*. It seems to belong to the genus of the *scombri*. Salviau has given the figure of it, but it is an imperfect one; for he has omitted the first fin of the back.

LYCÆA, Λυκαια, in *Antiquity*, an Arcadian festival resembling the Roman LUPERCALIA, in which the conqueror was rewarded with a suit of brazen armour.

LYCANTHROPY, Λυκανθρωπια, formed of Λυκος, *wolf*, and ἀνθρωπος, *man*, q. d. *man-wolf*, a species of madness, wherein those affected run, in the night-time, howling about the fields like wolves; and sometimes bite and hunt like dogs: whence the disease is also called by the ancients *cynanthropy*.

Lycanthropy is also used by some to express an imaginary metamorphosis of a man into a wolf, by magic power; wherein the persons affected seem not only to themselves in the form of wolves, but to others. See MADNESS.

LYCEUM, *Λύκειον*, in *Antiquity*, the name of a celebrated school, or academy, at Athens, where Aristotle explained his philosophy.

The place was composed of porticoes, and trees planted in the quincunx form, where the philosophers disputed walking. Hence *philosophy of the Lyceum* is used to signify the philosophy of Aristotle, or the Peripatetic philosophy. Suidas observes, that the *Lyceum* took its name from its having been originally a temple of Apollo *Lyceus*; or rather, a portico or gallery built by Lyceus, son of Apollo: but others mention it to have been built by Pisistratus, or Pericles.

LYCHNIDEA, in *Botany*. See PHLOX.

LYCHNIS, in *Botany*. See CAMPION.

LYCHNITES *macrior*. See MARBLE.

LYCIUM, in the *Materia Medica*, the name of a fruit called by the French *baye d'Avignon*, the AVIGNON *berry*, and by many authors the *grossularia*. The shrub which produces it is the *lycium sive pyracantha* of Gerard. See *Rhamnus* THORN. The fruit is about the size of a grain of wheat, and is not round, but of an angular form when dried, sometimes of three, sometimes of four angles, and sometimes dented in at one end like a heart. It is of a yellowish green colour, and of a bitter and astringent taste. It should be chosen fresh dried, and large. There was formerly a rob, or inspissated juice made from these berries, much in use in medicine; but this was generally adulterated with a rob made of the berries of the woodbine, privet, sloe, or other shrub, and is now quite out of use. The dyers in France and Holland use it for a yellow; and the Dutch have another use for it, which is, that they boil it in alum-water, and mixing it in whiting, form it into twisted sticks, which they sell to the painters in water-colours, under the name of *fil de grain*.

LYCOCTONON. See ACONITE.

LYCODONTES. See BUPONITE.

LYCOGALA, in *Botany*, a name by which Micheli has called several of the species of MUCOR.

LYCOIDES, a term used by medical writers to express the disorders which arise in the human body by a long retention of the seed. These are sometimes mischievous, and very often dangerous quinsies and swellings, and inflammations about the neck and throat. If we consider the natural tendency of the disorders of this kind to affect the neck, and the remarkable swelling of the necks of bucks, and some other animals at rutting time, it may give some rational hints towards understanding the alteration of the voice in boys who arrive at puberty.

Blancard derives the word *lycoides* from *λυκος lupus*, and *ειδος forma*, from a supposition that wolves are subject to this disorder.

LYCOPERDON, in *Botany*. See PUFF-*ball*.

LYCOPERSICON, in *Botany*; *love-apple*, *wolf's peach*, or *tomato*. Its characters are these: the flower, which has a permanent empalement of one leaf cut into five acute segments at the top, has one wheel-shaped petal, with a very short tube, and a large five-cornered brim, which spreads open and is plaited: it has five small awl-shaped stamina which close together: it has a roundish germen, which becomes a roundish fleshy fruit or berry, divided into several cells, including many flat seeds. There are seven species, one of which is the common POTATOE, Miller.

Linnæus has joined this genus and the melongena of Tournefort to the solanum, or NIGHTSHADE.

That species called tomatas is cultivated in many of our gardens, and its fruit eaten by the Spaniards and Italians, and by the Jew families in England, as we do cucumbers, with oil and vinegar, or else stewed in soups.

The plants are propagated by sowing their seeds in March on a moderate hot-bed. When they are come up two inches high they are to be transplanted into another bed of about the same temperature, where they are to be set at four inches distance. In this place they must be watered and shaded, and must have as much fresh air as may be; and in May they are to be transplanted into pots, or borders, and the branches, when they grow long, must be supported with sticks, otherwise the fruit which is grown large, will break them. They require frequent watering, and in August ripen their fruit, which grows to a large size, and makes a very pretty figure. But they should not be planted near habitations, for the leaves and stalks, when rubbed by the clothes in people's passing by, yield a very strong and very offensive smell.

LYCOPHTHALMUS, *the wolf's eye stone*, a name given by some authors to such pieces of agate or any other semipellucid stone, as chance to have circular spots in them, resembling in colour the eye of that animal.

LYCOPODIOIDES, in *Botany*, the name of a genus of mosses, the characters of which are these: it produces its seeds in spikes, in the manner of the *lycopodium*, or wolf's claw moss, but that in two ways; for some of the capsules include a powder, which seems only a farina; others seem to contain true seeds: these always stand to the number of three in each capsule. It differs from the *lycopodium* also in its general appearance and manner of growth, the leaves being all placed in the same plane, and expanded in the manner of fins, with an intermediate series of small leaves, which cover the upper side of the middle rib, or stalk. Of these mosses there are two orders: the first comprehends such as are creeping, or procumbent.

The second order of the *lycopodioides* comprehends those which are erect, or have some erect, and some procumbent or creeping branches, with erect shoots rising from them. Dillen. Hist. Muse. p. 405, &c. See *Tab. of Mosses*, N° 15.

LYCOPODIUM, in *Botany*, the name of a genus of mosses, the characters of which are these: it produces capsules in the axe of certain leaves, which are very unlike the capsules of the other mosses, having neither calyptra, operculum, nor pedicle: these do not stand as those of the *foliaceæ*, in all the axe of the leaves, but are collected together into a sort of spike of a scaly structure, and one capsule stands under every scale, or leaf: these capsules are of the shape of a kidney, and when ripe they separate longitudinally into two parts, and throw out a powder, consisting of round globules. It has been supposed by many, that this powder is the farina of the flower; but as there are no seeds found in any other part of the plant for it to impregnate, it seems much more probable opinion, that this powder, as well as that of the capsules of all the other mosses, is the true and genuine seed of the plant. In most of the species of this plant, the spikes are composed of leaves of a different figure from those of the rest of the plant, and are therefore called scales; but in some they are made of leaves of the same figure with those of the other parts of the moss. See *Tab. X. of Botany*, N° 14.

The first order of the *lycopodia*, according to Dillenius, consists of those which have their spikes supported on pedicles; and of these the first series are distinguished by the appellation of *juliformes*, from their spikes resembling the *jula*, or catkins of some trees, and being not of the same leaves with the rest of the plant.

The second series of the *lycopodia*, comprehends those whose spikes consist of leaves, the same with those of the other part of the plant.

The second order of the *lycopodia* comprehends those which have spikes not placed on pedicles. Linnæus enumerates twenty-four species of this genus, the characters of which are, that it has a bivalve sessile anthera and no calyptra.

LYCOPSIS, in *Botany*, the name of a genus of plants, the characters of which are these: the cup is a perianthium, divided into five broad, oblong, acute, and open segments, and remaining after the flower is fallen: the flower consists of a single petal, in form of a cylindric and crooked tube, the rim of which is slightly divided into five segments, and is obtuse: the opening is covered with five covex and prominent scales, converging one towards another: the stamina are five extremely small filaments, placed at the bending of the tube of the flower: the antheræ are small and covered: the pistil has four germina: the style is slender, and of the length of the stamina; and the stigma is obtuse and bifid: the cup is very large, and contains four oblong seeds.

LYCOPUS, in *Botany*. See *Water* HOREHOUND.

LYCOSTAPHYLA, *wolf's grapes*, in *Botany*, a name given by some of the Greek writers to the *solanum somniferum*, a kind of efculent nightshade, which we have much more properly called *lycopersicon*, the *wolf's peach*, its fruit being as large as a peach, and in nothing resembling a grape. Some of the Latin authors we find have called this *morelle*; and some, who have not understood this synonymous use of the word, have mistaken the writers to have meant the mushroom we call morel, when they prescribe this plant in fevers. The seeds of this plant are, however, what are usually prescribed in this case, and there is no danger therefore of these substituting the morel mushroom for it, if they will stick to the letter of the text; the seeds of that morella being too small to be gathered in such quantities as are prescribed.

Æmilius Macer tells us, that the nightshades, in general, were called by the name *morella* in his time: his words are, *herbam quam Græci strychnon dixere, Latini nos-*

rellum Arvum. The name *morello* seems to be formed upon the word *morion*, a name given both by the Greeks and Latins to one of the sleepy nightshades, and to the male mandrake of Dioscorides, which the shepherds were fond of eating; but which brought on sleepy disorders, if taken too largely.

LYCOSTOMUS, in *Ichthyology*, the name of a fish caught in the Baltic, but not very frequently, and approaching somewhat to the nature of the herring or pilchard. It is usually of five or six inches long, and so fat and fleshy, that its body is not flat, as all the herring kind have their's, but rounded; its *scales* are very small and loose, easily falling off on rubbing.

The name *lycostomus* is given by Ælian, and many other of the Greek authors to the ANCHOVY, called by others the *encrasicolus* and *encrasicholus*, and by the late writers *encrasicetus*. Artedi proves it to be only a species of the herring or clupea, and distinguishes it from the rest by the name of the *clupea* with the upper jaw longest.

LYCURGIA, λυκουργια, in *Antiquity*, a festival celebrated by the Spartans in memory of Lycurgus, whom they honoured with a temple, and an anniversary sacrifice.

LYDIAN, in *Ancient Music*, the second species of the diagason.

LYDIAN *mode*. See MODE.

LYDIUM *marmor*. See MARBLE.

LYDIUS *lapis*, in the *Natural History of the Ancients*, the name of the stone used by way of touch-stone for the trial of gold and silver, and called also by some *heraclius lapis*, both which names are also applied by the ancients to the load-stone, and hence have arisen no small misunderstandings of their works.

The true *lapis lydius*, or touch-stone, was anciently found only in the river Tmolus, but afterwards it was discovered in many other places, and is now very common in many of the rivers of Germany. The ancients give us very remarkable and circumstantial accounts of the uses they made of it, and it is plain they were able to discern the alloys in gold, by means of it with very great exactness. We at present use several different stones under this name, and for the same purpose; in Italy a green marble, called *verdello*, is what is most frequently used, and with us, very frequently, small pieces of the BASALTES, the same with that vast mass of black marble called the GIANT'S *causeway* in Ireland.

LYEMMER. See LEVINER.

LYGDINUM *marmor*. See MARBLE.

LYGEUM, *hooded matweed*, in *Botany*, a genus of the *triandria monogynia* class: the characters of which are, that it has a single-leaved spatha, two corollæ over the same germen, and that the fruit is a bilocular nut; there is only one species.

LYGDUS *lapis*, in *Natural History*, a name given by some of the ancients to the species of alabaster, which others of them called *marmor hyalinum*, by which name it was most usually known. See MARBLE.

LYGMOS. See HICCUP.

LYGON and LYGUS, in *Botany*, are used for AGNUS *castus*.

LYING-*in-woman*. The disorders that attend *lying-in-women* are principally these: the suppression, or immoderate flux of the lochia; the manner of curing which, see under LOCHIA. Inflammatory fevers are too common in these cases, and usually arise either from a retention of part of the secundines, a suppression of the lochia, or taking cold; or finally, from violent passions of the mind, such as anger, fear, joy, or the like. These fevers very often prove fatal, if not carefully treated. The best method in them, is to give the saline medicines joined to the absorbents, partly saturated with acids, and the usual attemperating powders of nitre, and the like. The discussion of the cause is at the same time to be attempted by the mild alexipharmics, among which the cortex eluteriæ holds a principal place, and with the use of these, the patient is to be kept in a gentle breathing sweat, during the course of the cure; the bowels must also be kept gently open, by means of mild suppositories, emollient clysters, or the gentle laxative medicines in small doses. The miliary fever often also attends *lying-in-women*, the method of cure in which see under *Puerperal* FEVER, and not unfrequently they fall into the *febris populatoria*, distinguished from the other by the broadness of the spots. This usually goes off by the use of attemperating and absorbent medicines, and a gentle diaphoretic regimen; and finally, after about fourteen days, it is proper to carry off the remaining sordes by some gentle doses of rhubarb.

A bilious diarrhœa is often also a complaint at these times. This is easily brought on by violent passions, or by drinking cold liquors, or such as are rancient and fermenting; and sometimes it succeeds a natural suppression of a flux of blood. This often proves a very terrible and fatal symptom, being attended with violent pains, and all inflammation of the intestines, accompanied with an inflammatory fever, especially when it continues longer than three or four days. In case of this symptom the method is to give absorbent powders, such as mother of pearl and the like; and after the matter has been corrected by this, and the other testaceous powders, as coral and crabs-eyes, the bitter extracts of gentian, &c. are to be given to strengthen the parts, and in the intermediate days small doses of rhubarb, and if it be necessary of opiates, or other anodynes carefully corrected. Astringents and an improper use of opium are very dangerous, and it is always proper to drink a large quantity of warm diluting liquors; if it be found necessary to give nitre, it must be mixed in small quantities with these liquors. See *Puerperal* FEVER.

Hysterics are also very common to women in child-bed, from improper discharges of the *lochia*: these are cured by giving internally the common absorbents with cats of antimony, oil of sweet almonds, inflated spirit of sal ammoniac, essence of orange peel; and, in people of hot habits, nitrous medicines, and the *spiritus mindereri*, with carminative broths, with a small quantity of saffron boiled in them.

After-pains are the greatest of all the complaints of *lying-in-women*, and withal the most common; these sometimes arise from difficult labour, sometimes from some part of the secundines being left, or from blood coagulated in the uterus; they also frequently arise from the improper evacuation of the lochia, whether they be too much, or too little in the quantity; also from colds from neglecting the proper binding or ligature of the abdomen after delivery; and finally, from the infant's sucking too violently while the mother is weak.

These pains are greatly mitigated by the carminative, aromatic and nervous medicines; such is the tincture of orange peel, scolozy, angelica-root, and camomile-flowers. Castor is to be particularly avoided in this case. Candied nutmegs are a very good medicine in it, and carminative broths, with the distilled waters of penny-royal, balm, cinnamon, and the like. External fomentations may be used at the same time, made of decoctions of rosemary, mint, elder-flowers, and bay-berries; and the common carminative clysters are often of the utmost service; and finally, the carminative oils, as that of carraway, and the like, may be rubbed on the pit of the stomach.

These pains seldom happen to women in their first *lying-in*; but they are not wholly exempt from them, for singular instances happen of their violence in those cases.

Swelling of the belly. This is another very common complaint with women after their *lying-in*; and usually is owing to the neglecting the proper ligatures about the abdomen after delivery. The cure for this is to be found in carminatives and resolvents, which first of all cleanse the womb from all its foulnesses, and afterwards restore it to its due tone. Bryony and hellebore roots in various forms, as also the leaves of botony, origanum and chervil serve to this purpose; and Stahl's or Becker's pills are of the most singular service, but all these things are to be used for some time.

Swelling of the pudenda. This is a symptom that usually takes its rise from difficult delivery; and besides the pain and other inconveniencies attending it, usually brings on a dysury. The proper remedies are ointments of elder and marshmallows, with the camphorated white ointment, commonly called by the good women simply unguentum. Bags of camomile flowers, with fennel, and a little camphor, boiled in milk, and then lightly squeezed, are also of great service. When the dysury continues after the swelling is taken down, it is then to be treated in the common way. When there is any actual wound in the parts, the liquor of myrrh, or oil of eggs, and other balsams are to be used, but all fatty substances are to be carefully avoided, as they usually occasion tumors.

Proper treatment of lying-in-women. As soon as ever they are delivered, they are to be put immediately into a warm bed, and the belly wound round with a broad swathe or roller; they are then to be kept with the utmost care from external cold; for the sweats, on the one hand, and the lochia on the other, make them extremely susceptible of mischief that way; and the consequence is a suppression of the lochia with fevers of a very dangerous kind, tumors of the abdomen, and many other terrible complaints. They are then to be kept extremely quiet, and if they are not in danger of fainting, they are to be suffered to sleep as soon as possible, but if there be any suspicion of fainting, they must be kept awake three or four hours after delivery. Their strength is then to be restored by broths of tender meats, as chicken, or the like, and by caudles. And the use of jellies, as of harti-

horn, and the like, is to be freely indulged. After the fourth day, when the painful buſineſs of the MILK is over, they may be indulged with good wine, drank alone, in moderate quantities. The heat of the room is to be all the time preſerved as equally as may be; and they are to be allowed to drink as much warm liquors as they pleaſe, but they muſt not touch any cold ones. The ſeveral excretions are carefully to be regarded, eſpecially the lochia. Great care muſt be taken that this diſcharge is not rendered too great by means of hot medicines, or a too hot regimen, nor ſuppreſſed by a cold regimen, or by the cold air. A gentle ſweating is to be encouraged, and promoted during the whole time; and even, if this become very conſiderable, in people of corpulent habits, it is not to be checked. Coſtiveneſs, during the two or three firſt days, is not to be regarded, for the vital principle is at that time ſo much engaged in the ſecretions of the lochia and milk, that it is no wonder if the bowels are leſs ſtimulated. No means are to be uſed to irritate the bowels in this time, nor ſhould the ſtomach be loaded with ſolid foods. After theſe firſt days are over, if the coſtiveneſs remains, it is proper to give glyſters at times, to make the patient take lubricating broths, and now and then ſwallow a little oil of ſweet almonds.

All paſſions of the mind are to be avoided in the moſt careful manner, and all occaſions of them kept from the patient. Fear is often known to ſtop the lochia, and anger to bring on hæmorrhages of a dangerous kind, and ſometimes fevers and bilious diarrhœas, and both often throw the patient into faintings. The light is to be kept out of the room in a great meaſure; for it often happens that the ſight is much impaired, and the eyes weakened in render perſons; and ſometimes noiſes and ringing in the ears, ſometimes deafneſs is brought on.

Talking much is very improper in theſe caſes, as it eaſily throws the blood into commotions; and it is to be carefully obſerved, that when the exceſſive flux of the lochia has rendered the patients very weak, and often ſubject to faintings; they are by no means to be indulged in that ſleepineſs which uſually grows upon them; for they ſometimes die in ſuch ſleeps. Bags of carminative ingredients are very properly applied to the abdomen, during the firſt days of *lying-in*, for they greatly prevent flatulencies; and it is a very good cuſtom, of ſome people, to apply cloths wetted in wine to the pudenda, when ſwelled, or otherwiſe injured in delivery. In young people, eſpecially thoſe of plethoric habits, all hot things are to be avoided, and wine is to be uſed with great caution and circumſpection. If the blood is on any occaſion thrown into commotion, abſorbents and nitrous medicines are proper; when the perſon is of a weak conſtitution, ſhe is not to be ſuffered to get out of bed until the firſt nine days are over, and not to leave her room until a month, or until five or ſix weeks are over, and then it is proper to give a doſe or two of ſome gentle purge. See DELIVERY, LOCHIA, MILK, and MOLA.

LYING *under the ſea*, in *Sea-language*, is when, in a ſtorm, the ſhip is a-hull, and the helm ſo faſtened a-lee, that the ſea breaks upon her bow, or broadſide.

LYING *along* denotes the ſtate of a ſhip, when preſſed down ſideways by a weight of ſail in a freſh wind that croſſes the ſhip's courſe either directly or obliquely.

LYING-*to*, or LYING-*by*, denotes the ſituation of a ſhip when ſhe is retarded in her courſe, by arranging the ſails in ſuch a manner as to counteract each other with nearly an equal effort, and render the ſhip almoſt immoveable, with reſpect to her progreſſive motion, or head-way. A ſhip is uſually *hringd-to* by the main or fore-top-ſails, one of which is laid a-back, whilſt the other is full; ſo that the latter puſhes the ſhip forward, whilſt the former reſiſts this impulſe, by forcing her a-ſtern. This is particularly practiſed in a general engagement, when the hoſtile fleets are drawn up in two lines of battle oppoſite to each other; it is alſo uſed to wait for ſome other ſhip, either approaching or expected; or to avoid purſuing a dangerous courſe, eſpecially in dark or foggy weather, &c. Falconer.

LYING-*to in a ſtorm*. See TAVING.

LYLAC, in *Botany*. See LILAC.

LYMPHÆA, among the *Romans*, a kind of grottoes, or artificial caves, ſo called from *lympha*, *water*; becauſe they were furniſhed with a great many tubes, canals, and ſecret paſſages, through which the water ſuddenly guſhed upon the ſpectators, while buſy in admiring the great variety and beautiful arrangement of ſhells, with which the grotto was adorned.

LYMPH, LYMPHA, in *Anatomy*, a thin tranſparent humour, ſomething like water, ſecreted from the ſerum of the blood in all parts of the body, and returned to the blood again, by proper ducts of its own, called *lymphatics*, and ſuppoſed, by ſome, to be the immediate matter of nutrition.

If the *lymph* be chemically examined, it will be found to contain a great deal of volatile, but no fixed ſalt, ſome phlegm, ſome ſulphur, and a little earth.

The uſe of the *lymph* may be gathered from the conſideration of the parts into which it diſcharges itſelf. That which comes from the head, neck and arms, is thrown into the jugular and ſubclavian veins. All the lymphatics, which the parts in the cavity of the thorax ſend out, empty themſelves into the thoracic duct; and the *lymphæ*, from all the reſt of the body, flows to the common receptacle: ſo that there can be no doubt, but that its chief uſe is to dilute and perfect the chyle, before it mixes with the blood.

The late ingenious Mr. Hewſon uſes the term *lymph* to denote that part of the blood which jellies, or becomes ſolid ſpontaneouſly, when blood is received into a baſon, and, therefore, this coagulable *lymph*, which ſome have called the fibrous part of the blood or the gluten, and which, by becoming ſolid, gives firmneſs to the CRASSAMENTUM, ought not to be confounded with the SERUM of the blood, which alſo contains a ſubſtance that coagulates, when expoſed to heat, or when mixed with ardent ſpirits, or ſome other chemical ſubſtances; though it remains fluid when merely expoſed to the air. That the coagulable *lymph* gives firmneſs to the craſſamentum, whilſt the red particles of which it conſiſts give the red colour to the blood, is proved by agitating freſh blood with a ſtick, ſo as to collect this *lymph* on the ſtick, in which caſe the reſt of the blood remains fluid: and theſe two parts may be ſeparated by waſhing the craſſamentum in water, the red particles diſſolving in the water, whilſt the coagulable *lymph* remains ſolid. Mr. Hewſon, in the courſe of his experiments on this ſubject, has found, that neutral ſalts mixed with the blood, when juſt received from the vein, prevent its coagulation, or keep it fluid; but upon adding water to the mixture, it then jellies or coagulates; and on ſhaking the jelly, the coagulum will be broken, and the part ſo coagulated can be now ſeparated as it falls to the bottom, and proves to be the *lymph*. Moreover the blood, thus kept fluid by neutral ſalts, ſtill retains its property of being coagulable by heat, and by other ſubſtances as before, air excepted.

The coagulable *lymph* from various cauſes becomes ſolid in the body, and occaſions various obſtructions and inflammations: it appears therefore, to be a deſideratum of conſiderable importance, to aſcertain the cauſe of that coagulation which it always, and generally very ſoon undergoes, when it is out of the body. With this view Mr. Hewſon conſiders the particular circumſtances, in which blood, received into a baſon and there coagulating, differs from that flowing in the veſſels of a living animal. The moſt obvious and material differences are, that, in the firſt caſe, it is expoſed to the action of the air, and to that of cold, and that it is at reſt. In the laſt caſe, all theſe circumſtances are wanting. From the whole of his experiments, it appears, that the blood, when out of the body, coagulates as ſoon, when agitated and kept warm, as it does when ſuffered to reſt and to cool; and, from a compariſon of the whole, there is reaſon to conclude, that the air is a ſtrong coagulant of the blood; and that the change which this fluid ſoon undergoes in its conſiſtency, when taken from the veins, is chiefly owing to the action of that element, and not to cold, or want of motion. His experiments likewiſe tend to prove, that the inflammatory cruſt, SIZE, or BUFF, which often appears on the blood in inflammatory diſorders, is not forced from the ſerum, but from the fixation of the coagulable *lymph*, after the red particles have ſubſided. It appears alſo from his experiments and obſervations, that fizy blood coagulates much more ſlowly than other blood; that inflammation actually leſſens the diſpoſition of that fluid to coagulate; and, that in inflammatory diſorders, where this whitiſh cruſt or fize appears, the blood, or at leaſt the coagulable *lymph*, which conſtitutes this inflammatory fize is nearly attenuated. It appears farther, that the common opinion, that cold coagulates blood, is ſo far from being true, that the *lymph*, on being cooled, is deprived of its power of coagulation, when expoſed to the air. He alſo concludes, that bleeding alters the nature of the blood, not by removing the vitiated part, and giving room for new blood to be formed, as has been ſuppoſed, but probably by changing that ſtate of the blood-veſſels, on which the thinneſs of the *lymph*, and the leſſening of its tendency to coagulate, depend. And although bleeding does in general weaken the action of the veſſels, increaſe the diſpoſition of the blood to coagulate and even thicken the *lymph*, yet it may happen, that the taking away blood in the ordinary quantity, may produce none of theſe effects. Phil. Trans. vol. lx. art. 32, 33, 34. See BLOOD, HÆMORRHAGE, HEAT, INFLAMMATION, and LYMPHATICS.

LYMPHATI or LYMPHATICI, in *Antiquity*, a name given by the Latins to poſſeſſed or mad perſons, becauſe they were thought to be gifted with divination. Plin. Nat. Hiſt. lib. xxv. cap. 5 p. 386. edit. Hard.

Theſe anſwer to the νυμφόληπτοι of the Greeks: the ancient Greeks called water *νυμφα*, which the Latins changed into *lympha*. The term *nympha*, ſays Mr. Bryant, is of great antiquity, and denotes an oracular influence by which people obtained an inſight into the ſecrets of futurity: it was written *nympha* or *amphi*, and ſignified the oracle of Ham, who, according to the Egyptian theology, was the ſame as the ſun, or Oſiris: and as fountains were deemed ſacred, theſe were ſtyled by the Amonians *Ain Ompha*, or the fountains of the oracle, from the divine influence with which they were ſuppoſed to abound, which terms were afterwards contracted by the Greeks into *νυμφη*, *a nymph*, who ſuppoſed ſuch a perſon to be an inferior goddeſs who preſided over waters. In the ſame manner from *ai omphoi* was derived *lympha*, which differed from aqua or common water, becauſe it was of a ſacred or prophetic nature. Analyſis of Ant. Myth. vol. i. p. 280.

LYMPHATICS, or LYMPHEDUCTS, a ſort of fine, ſmall, tranſparent veſſels, generally ariſing from the glands, and conveying back to the blood a tranſparent liquor, called *lymph* or *lympha*.

Theſe, though not ſo viſible as the other veſſels, becauſe of their minuteneſs and tranſparency, are, however, exiſtent in all parts of the body; but the difficulty of finding them has prevented their being deſcribed in many parts. The *lymphatics* are contracted at ſmall and unequal diſtances by two oppoſite ſemilunar valves, which permit the lymph to paſs through them towards the heart; but ſhut, like flood-gates upon its returning.

They ariſe in all parts of the body, but after what manner, needs no great diſpute; for, without doubt, all the liquors in the body, excepting the chyle, are ſeparated from the blood in the fine capillary veſſels, by a different pipe from the common channel, in which the reſt of the blood moves: but whether this pipe be long or ſhort, whether it be viſible or inviſible, it is ſtill a gland, whilſt it ſuffers ſome part of the blood to paſs through it; denying a paſſage to the reſt.

Now, the glands which ſeparate the lymph muſt be of the ſmalleſt kind, for they are inviſible to the fineſt microſcope; but their excretory ducts, the *lymphatic* veſſels, unite with one another, and grow larger, as they approach the heart: yet they do not open in one common channel, as the veins do; for ſometimes we find two, or three, or more *lymphatics*, running by one another; which only communicate by ſhort intermediate ducts, and which unite and immediately divide again. In their progreſs, they always touch at one or two conglobate or veſicular glands, into which they diſcharge themſelves of their *lympha*. Sometimes the whole *lymphatic* opens at ſeveral places, into the gland; and ſometimes it ſends in only two or three branches, whilſt the main trunk paſſes over and joins the *lymphatics* which ariſe from the oppoſite ſides of the gland, exporting again their lympha to their common receptacle.

The glands of the abdomen, which receive the *lymphatics* from all its parts, as likewiſe from the lower extremities, are the glandulæ inguinales, ſacræ, iliacæ, lumbares, meſentericæ, and hepaticæ; all which ſend out new *lymphatics*, which pour their contents into the receptaculum chyli; as thoſe of the cheſt, head, and arms, do into the ductus thoracicus, jugular, and ſubclavian veins.

Theſe glands are round and ſmooth bodies, about the bigneſs of a hazle-nut, bigger or leſſer, according to the number of *lymphatics* they receive. Their ſubſtance is membranous, and their whole bulk divided into little cells, which receive the lymph from the *lymphatics*; and are therefore improperly called *glands*, becauſe they ſeparate no liquor from the blood. It is true, that their exporting *lymphatics*, communicating with their arteries, do receive a lymph from them; but this is done without the help of conglobeate glands; as the lacteal veins do with the capillary arteries of the guts: the chief uſe of theſe veſicular bodies ſeems to be, that the ſlow-moving lympha may receive a greater velocity from the elaſtic contraction of their membranous cells, as well as from the new lymph immediately derived from the arteries. See GLAND.

Dr. Akenſide, in his account of the origin and uſe of the *lymphatic* veſſels of animals, concludes, that they have their origin, in general, among the little cavities of the cellular ſubſtance of the muſcles, among the mucous folliculi of the tendons, or the membranous receptacles and ducts of the larger glands; that their extremities or roots do, from theſe cavities, imbibe the moiſture exhaled there from the ultimate arterial tubes, juſt as the lacteals (the *lymphatics* of the meſentery) do on the concave ſurface of the inteſtines: and that the minute imbibing veſſels, by gradually opening into one another, form at length a *lymphatic* trunk, furniſhed with valves to prevent the return of its fluid, and tending uniformly, from the extremities, and from the viſcera to reconvey to the blood that lymph with which they are kept in perpetual moiſture; which is indiſpenſibly neceſſary to life and motion; while, at the ſame time, the continual reabſorptions of that moiſture by the *lymphatics* is no leſs neceſſary, in order to preſerve the blood properly fluid, and to prevent the putrefaction, which would inevitably follow, if this animal vapour be ſuffered to ſtagnate in the cavities where it is diſcharged. Phil. Tranſ. vol. L. p. 328.

Mr. Hewſon's doctrine on this ſubject is, that the *lymphatic* ſyſtem and its appendages, in which he includes the *lymphatic* veſſels, the *lymphatic* glands, the THYMUS, and the SPLEEN, are the elaboratory which nature uſes, or the organs which ſhe employs in fabricating the particles of the BLOOD, which he deſcribes as round, flat, red veſicles containing ſmall and ſolid particles in their centres. He ſhews, that the *lymphatic* glands ſecrete a fluid, in which may be ſeen, by means of the microſcope, numberleſs ſmall ſolid particles, exactly reſembling, in ſize and ſhape, the central particles contained in the middle of the veſicles. He obſerves farther that, after a *lymphatic* veſſel has emerged from a *lymphatic* gland, central particles are found to have acquired their veſicular portions, and that they are now become real particles of red blood completely formed. He conjectures, that this newly acquired veſicle may either be a ſecretion from the internal coat of the *lymphatic* veſſel; or, that this veſſel has a plaſtic power over its contained fluid, ſo as not only to form a veſicle round the central particle, but alſo to give its red colour; for, till the red veſicle is formed, the central particle is evidently white. See Experimental Inquiries, part the 3d, &c. &c. being the remaining part of the Obſervations and Experiments of the late Mr. W. Hewſon, F. R. S. By Magnus Falconer, 1777.

The *lymphatic* ſyſtem is not confined to the human ſpecies: Mr. Hewſon diſcovered it in birds, fiſh, and amphibious animals. See LACTEALS.

LYNCHET, among *Farmers*, a line of green ſward, ſerving as a boundary to ſeparate ploughed land, in common fields. See BALK.

LYNCIS *lapis*, in *Natural Hiſtory*, the name given by moſt of the writers of the middle age to the BELEMNITES.

LYNCURIUS *lapis*, in the *Natural Hiſtory of the Ancients*, the name of a ſtone about which there have been various diſputes among the later writers. Theophraſtus has left us this account of it; that it was hard, and uſed for engraving ſeals on, and was of a very ſolid texture like the gems; that it had an attractive power like amber, and was pellucid, and of a flame colour.

Dr. Woodward believed this ſtone to be a ſpecies of the BELEMNITES, to which it is objected, that this is neither pellucid nor fit for engraving ſeals upon, neither can it by any management be made to attract ſtraws and other light bodies.

M. Geoffroy conſiders it as AMBER; but this ſubſtance, though it has the attractive power mentioned by Theophraſtus, has not the firm texture requiſite to have ſeals engraved upon it, neither is it ſo very hard, as is expreſſly ſaid by this author concerning the *lyncurium*, as to require great labour in poliſhing it.

All that the ancients have ſaid about it, determines that it was really one of the gems, and that it was of a flame colour; and this deſcription agrees perfectly, ſays Dr. Hill, with the gem we call the HYACINTH, and this doubtleſs was the ſtone they knew by that name; ſince it is plain by the antique heads we ſee cut in it, that it was in common uſe among them; and it is plain from all their writings, that they did not know it by any other name: what they called the hyacinth being a very different ſtone, and one to which that name much more properly belonged, being a blue amethyſt than the common kind, and ſomewhat reſembling the colour of the hyacinth flower. The ancients have ſpoken of three or four kinds of it, that is, three or four varieties in degree of colour; and we alſo, at this time, are acquainted with the very ſame varieties. What they called the male and female *lyncurium*, were plainly our deeper and paler hyacinth; and the fine *lyncurium*, deſcribed by Pliny, our hyacintha la bella. Hill's Theophraſt, p. 75.

Dr. Watſon, in his obſervations relating to the *lyncurium* of the ancients makes it extremely probable, that the *lyncurium* of Theophraſtus is the TOURMALIN, which agrees with his deſcription in all its ſenſible qualities; viz. that it is a very hard pellucid ſtone, of a deep red colour; that it is very proper to engrave ſeals upon; that it attracts like amber, not only ſtraws and light pieces of wood,

wood, but filings of iron and brass. Phil. Transf. vol. li. art. 37. p. 394.

LYNX, in *Zoology*, the name of a very fierce beast of prey, called in English the *ounce*, and by many Latin authors the *lupus cervarius*, or deer-wolf, from its loving to feed on deer. This animal, in the Linnæan system, is a species of *felis* or cat, with a short tail, black at the end, and ears tufted with black long hairs. See *Tab.* III. *of Quadrupeds*, N° 30.

Pliny seems to distinguish the *lynx* from the *lupus cervarius*, but there seems not the least reason for it. The principal colours of this creature are a whitish and a purplish yellow, variegated with numerous very beautiful round spots like eyes, in the manner of the *leopard*; these are usually black. Sometimes it is seen also of a plain fox-colour on the back, and full of black spots, and grey on the belly, and inner part of the legs, with the like spots as on the back and sides, but larger, of a somewhat paler colour, and fewer in number.

The hairs of this creature, as well such as appeared reddish, as those which were grey, when nicely examined, are all found to be truly of three colours in each single hair; the middle part being of a reddish tawney, the bottom grey, and the top white; but those which compose the black spots are only of two colours, there being no white at their ends.

This creature's eyes are extremely bright and vivid, and shew plainly that it has a very piercing sight. Its ears are like those of a cat, but have this peculiarity, which distinguishes the creature from all the animals of the same class, that they have a fine pencil of black hairs growing out at their extremities, very smooth, and of a deep black like velvet, and two fingers long. Its tongue is rough like that of the lion. The *lynx* is found wild in Italy and Germany, but the greater number are in Asia, and these are much finer coloured than the European. They all differ considerably from one another, at times, in the number and disposition of their spots. The greater number is found in the north of Europe, Asia, and America, whence the furs, which are valuable for their softness and warmth, are annually imported.

There are several varieties differing in size and colour. Pennant mentions a distinct species, under the name of the *bay lynx*, inhabiting the inner parts of the province of New York; and the Prussian *lynx*, for which see SIGAHGUASH. Ray and Pennant.

LYNX, in *Mythology*, was a fabulous animal consecrated to Bacchus.

LYNX, in *Astronomy*, is a constellation of the northern hemisphere, made by Hevelius out of unformed stars: the number of stars in Hevelius's catalogue is nineteen, and in the Britannic is forty-four, their names, places, longitudes and latitudes, and magnitudes are as follow:

Situation of stars.	Signs.	Longit.	Latitude N.	Magnitudes.

LYRA, in *Astronomy*, a constellation in the northern hemisphere.

The number of its stars, in Ptolemy's catalogue is ten, in Tycho's eleven; in Hevelius's seventeen; and in the Britannic catalogue twenty-one; the names, places, longitudes, latitudes, and magnitudes whereof are as follow:

Stars in the conſtellation *Lyra*, or *Vultur Cadens*.

Names and ſituation of the ſtars.	Signs.	Longit.	Latitude N.	Magnitudes.

LYRA, in *Ichthyology*, the name of a fiſh of the *trigla* kind, of which there are two varieties, reckoned by Artedi and Linnæus two different ſpecies. The one the *piper* or TIBIGEN. The other the *lyra cornuta*, or horned harp-fiſh. This laſt is a fiſh of an octagonal form, covered all over with bony ſcales: theſe are of a rhomboidal figure, and each has in its middle a ſharp and ſtrong prickle bending backwards; it is of a red colour, and its head is very large; its ſnout divides towards the extremity into two long horns, on which are placed two perpendicular ſpines, and a third above makes an acute angle with theſe; it has one very long fin on the back, and another anſwering to it behind the anus: alſo two large ones at the gills, and two ſmaller on the belly; it has only two filaments, called fingers, behind its gill-fins; its mouth is large, but has no teeth, and there are ſeveral beards on its under-jaw; two of which are longer than the reſt, and are branched; it is caught in the Mediterranean, and brought to market at Rome; it is a ſcarce fiſh in other places, and at Montpelier was one ſhewed to Mr. Ray for the *remora*. See *Tab.* III. *of Fiſh*, N° 33.

LYRA is alſo the name of a beautiful ſea-ſhell of the genus of the *concha globoſa*, or dolium. There are three ſpecies of the *lyra*, or harp-ſhell. 1. The common *lyra*, which has thirteen roſe-coloured ribs running along its body. 2. The eleven-ribbed *lyra*; and 3. the noble harp, or *lyra nobilis*. This is a moſt elegantly variegated ſhell; its ground colour is a deep brown, and its variegations very elegant and black.

LYRA *luteſcens*. See LUCIDA.

LYRATUM *folium*, among *Botaniſts*. See LEAF.

LYRE, Lyra, a ſtringed inſtrument much uſed among the ancients; ſaid to be invented by Mercury, about the year of the world 2000, on occaſion of his finding a dead ſhell-fiſh, called by the Greeks, *chelone*, and Latins, *teſtudo*, left on an inundation of the Nile; of the ſhell whereof he formed his *lyre*; mounting it with ſeven ſtrings, according to Lucian, and adding a kind of jugum to it, to ſtretch or looſen the ſtrings.

Boetius relates the opinion of ſome, who ſay, that Mercury's *lyra* had but four ſtrings, in imitation of the mundane muſic of the four elements. Diodorus Siculus ſays it had but three ſtrings, in imitation of the three ſeaſons of the year; which were all the Greeks counted, viz. ſpring, ſummer, and winter. Nicomachus, Horace, Lucian, and others, make it have ſeven ſtrings, in imitation of the ſeven planets.

This three, four, or ſeven-ſtringed inſtrument, they ſay, Mercury gave to Orpheus; who being torn to pieces by the Bacchantes, the *lyre* was hung up by the Leſbians in Apollo's temple. Others ſay, Pythagoras found it in ſome temple in Egypt, and added an eighth ſtring. Nicomachus ſays, that when Orpheus was killed, this *lyre* was caſt into the ſea, and thrown up at Antiſſa, a city of Leſbos; where the fiſhermen finding it, gave it to Terpander, who carried it into Egypt, and called himſelf the inventor. The ſeven ſtrings were diatonically diſpoſed, by tones and ſemitones; and Pythagoras's eighth ſtring made up the octave.

Mr. Barnes, in the prolegomena to his edition of Anacreon, has an inquiry into the antiquity and ſtructure of the *lyre*; of which he makes Jubal the firſt inventor. For the ſeveral changes this inſtrument underwent, by the addition of new ſtrings, he obſerves, that, according to Diodorus, it had originally only three; whence it was called τριγωνος. Afterwards it had ſeven ſtrings; as appears from Homer, Pindar, Horace, Virgil, &c. Feſtus Avienus gives the *lyre* of Orpheus nine ſtrings. David mentions an inſtrument of that ſort ſtrung with ten, *in pſalterio decachordo*. Timotheus of Miletus added four to the old ſeven, which made eleven. Joſephus, in his Jewiſh Antiquities, makes mention of one with twelve ſtrings; to which were afterwards added ſix others, which made eighteen in all. Anacreon himſelf ſays, p. 253. of Mr. Barnes's edition, *cantu viginti tetis chordis*. As for the modern *lyre*, or Welch HARP, it is ſufficiently known. From the *lyre*, which all agree to be the firſt inſtrument of the ſtringed kind in Greece, there aroſe an infinite number of others, different in ſhape, and number of ſtrings; as the pſalterium, trigon, ſambucus, pectis, magadis, barbiton, teſtudo (the two laſt uſed promiſcuouſly, by Horace, with the *lyre* and *cithara*), epigonium, ſimmicum, and pandura; which were all ſtruck with the hand, or a plectrum. See PSALTERY, SAMBUCA, MAGADIS, BARBITON, and CITHARA.

LYRE, among painters, ſtatuaries, &c. is an ATTRIBUTE of Apollo and the Muſes.

LYRIC, ſomething ſung or played, on the LYRE or HARP.

LYRIC is more particularly applied to the ancient odes, and ſtanzas; which anſwer to our *airs*, or *ſongs*, and may be played on inſtruments.

The ancients were great admirers of *lyric verſes*; which name, Mr. Barnes obſerves, they gave to ſuch verſes as were ſung to the lyre.

This ſpecies of poetry was originally employed in celebrating the praiſes of gods and heroes; though it was afterwards introduced into feaſts, and public diverſions: it is a miſtake to imagine Anacreon, as the Greeks do, the author of it; ſince it appears from Scripture to have been in uſe above a thouſand years before that poet. Mr. Barnes ſhews how unjuſt it is to exclude heroic ſubjects and actions from this ſort of verſe, *lyric poetry* being capable of all the elevation and ſublimity ſuch ſubjects require; which he confirms by the example of Alcæus, Steſichorus, Anacreon, and Horace, and by his own eſſay, A triumphal Ode inſcribed to the Duke of Marlborough, at the head of this edition: he concludes with the hiſtory of *lyric poetry*, and of thoſe ancients who excelled in it.

The characteriſtic of *lyric* poetry, which diſtinguiſhes it from all others, is *dignity* and *ſweetneſs*. As *gravity* rules in heroic verſe; *ſimplicity*, in paſtoral; *tenderneſs* and *ſoftneſs*, in elegy; *ſharpneſs* and *poignancy*, in ſatire; *mirth*, in comedy; the *pathetic*, in tragedy; and the *point*, in epigram; ſo in the *lyric*, the poet applies himſelf wholly to ſooth the minds of men, by the ſweetneſs and variety of the verſe, and the delicacy and elevation of the words and thoughts; the agreeableneſs of the numbers, and the deſcription of things moſt pleaſing in their own nature.

LYRODI, among the *Ancients*, a kind of muſicians who played on the LYRE, and ſung at the ſame time.

LYRODI was alſo an appellation given to ſuch as made it their employment to ſing lyric poems, compoſed by others.

LYSANDRIA, Λυσανδρια, in *Antiquity*, a Samian feſtival celebrated with ſacrifices and games, in honour of Lyſander the Lacedæmonian admiral. It was anciently called *hereo*, which name was aboliſhed by a decree of the Samians.

LYSIARCHA, an ancient kind of magiſtrate, being the pontiff of Lycia, or ſuperintendent of the ſacred games of that province.

Strabo obſerves, that the *lyſiarcha* was created in a council conſiſting of the deputies of twenty-three cities; that is, of all the cities in the province; ſome of which cities had three voices, others two, and others but one.

Cardinal Norris ſays, that the *lyſiarcha* preſided in matters of religion; in effect, the *lyſiarcha* was nearly the ſame with the *aſiarcha*, and *friarcha*; who though they were all the heads of the councils, or ſtates of thoſe provinces, yet were they eſtabliſhed principally to take care of the games and feaſts celebrated in honour of the gods, whoſe prieſts they were inaugurated, at the ſame time that they were created *lyſiarchæ*, *friarchæ*, or *aſiarchæ*.

LYSIMACHIA. See *Loose-ſtrife*.

LYSIMACHIA-*worm*, in *Natural Hiſtory*, a name given to an inſect found very frequently feeding on the leaves of the *lyſimachia*, or willow-herb. It has uſually been eſteemed a caterpillar, but is properly one of the PAUSSE *rhenilli*, having a rounded head, and twenty-two legs; this creature changes its ſkin ſeveral times, and finally changes its colour with it; it is at firſt of a bluiſh grey, but on its laſt change in the worm-ſtate it becomes of a yellowiſh green; when it has lived a week or thereabout, after this laſt change, it becomes a chryſalis, from which there afterwards comes out a four-winged fly.

LYSSA, λυσσα, a word uſed by medical authors to expreſs that ſpecies of madneſs which is peculiar to dogs and wolves, but is communicated by their bite to man and other animals. Hence perſons labouring under the diſmal effects of ſuch a bite, are called alſo *lyſſodecti*.

LYTHRUM, in *Botany*, a name by which Linnæus calls a genus of plants, named by Tournefort, and other authors, *ſalicaria*. See *Purple* LOOSE-*ſtrife*.

M.

M. A liquid conſonant, and the twelfth letter in the alphabet.

It has one invariable ſound, and is pronounced by ſtriking the upper lip againſt the lower; in which the pronunciation of this letter agrees with that of *b*; the only difference between the two conſiſting in a little motion made in the noſe in pronouncing *M*, and not in *b*: whence it happens, that thoſe who have taken cold, for *M* ordinarily pronounce *b*; the noſe, in that caſe, being diſabled from making the neceſſary motion.

All conſonants are formed with the aid of vowels; in each the vowel precedes, in *br* it follows: and *M* is never mute.

Quinctilian obſerves, that the *M* ſometimes ends Latin words, but never Greek ones; the Greeks always changing it in that caſe into *n*, for the ſake of the better ſound.

M is alſo a numeral letter, and among the ancients was uſed for a thouſand; according to the verſe,

M cupit eſſe meum, quem ſcimus mille tenere.

When a dath is added at the top of it, as $\overline{M}$; it ſignifies a thouſand times a thouſand.

M as an abbreviature ſtands for Manlius, Marcus, Martius, and Mucius: *M. A.* ſignifies *magiſter artium*, or maſter of arts; *MS.* manuſcript, and *MSS.* manuſcripts.

M. in *Aſtronomical Tables*, and other things of that kind, is uſed for *Meridionali* or ſouthern; and ſometimes for *Meridies*, or mid-day.

M. in *Medicinal Preſcription*, is frequently uſed to ſignify a maniple, or handful: and it is ſometimes alſo put at the end of a recipe, for *miſce*, *mingle*; or for *mixtura*, *a mixture*. Thus, ex. *ſ. julapium*, ſignifies *mix*, and *make a julap*.

M. in *Law*, the brand or ſtigma of a perſon convicted of man-ſlaughter, and admitted to the benefit of his clergy. It is to be burnt on the brawn of his left thumb.

MABBY, a kind of wine made from potatoes. It is ſaid to be uſed in Barbadoes.

MABOUJAS, the *deciduous*, in *Zoology*, a ſpecies of American lizard, ſo called from its uglineſs and diſagreeable aſpect. It grows to ſix or ſeven inches long, and to the thickneſs of a thumb, and is found in the trunks of rotten trees, and in marſhy places, where the ſun-beams ſeldom reach; it is all over of a gloſſy black colour, and looks as if ſmeared over with oil.

MAC, an Iriſh word ſignifying *ſon*; frequently preſixed to ſurnames: as *Macdonald* for Donald's ſon, *Maclaurin* for Laurence's ſon, &c.

MACAM, *Indian apple*, in *Natural Hiſtory*, the name of a common Eaſt Indian fruit; it is of a round ſhape, and about the ſize of our common wild crabs which grow in the hedges; inſtead of the ſeveral ſmall ſeeds, which our crabs and apples contain, this fruit has only one hard kernel; it is of an acid taſte, and of a raw and not very agreeable ſmell; the tree which produces this fruit, does not grow to any great height; it reſembles the quince-tree in its leaves, except that they have a yelloviſh caſt. Mem. Acad. Par. 1699.

MACAO, in *Zoology*. See MACAW.

MACAQUO, in *Zoology*, the name of a large ſpecies of monkey, called by Mr. Ray *cercopithecus Angolenſis major*, the great Angola monkey. Its hair is ſometimes of the colour of that of a wolf, but that of others is brown, tinged with yellow or olive; its noſtrils are elate, and divided like thoſe of a hare; its head like a bear's; its eyes ſmall; its buttocks are bald; on theſe he frequently ſits upright: he always carries his tail bent into a ſort of arch; his length, from the head to the inſertion of the tail, is more than a foot; his tail is rather ſhorter than his body; his legs are conſiderably long, and his body remarkably fat and bulky; his teeth are extremely white; and his penis very much reſembles that of a man: it is an extremely lively animal, and continually plays a number of antic tricks; its voice is ſhrill, and its only noiſe hah! hah! See CERCOPITHECUS.

They have another ſpecies of this kind alſo about Angola, which may be called the black *macaque*. Its only colour is black; but on many parts of the back and ſides, there is a greyiſh caſt among it: this has a tail of remarkable length, being more than two foot long.

MACARIANS, in *Eccleſiaſtical Hiſtory*, the followers of Macarius, an Egyptian monk, who was eſtabliſhed towards the cloſe of the fourth century for his ſanctity and virtue. In his writings there are ſome ſuperſtitious tenets, and alſo certain opinions that ſeem tainted with Origeniſm. The name has been alſo applied to thoſe who adopted the ſentiments of Macarius, a native of Ireland, who, about the cloſe of the ninth century, propagated in France the error afterwards maintained by Averrhoes, that one individual intelligence or ſoul performed the ſpiritual and rational functions in all the human race.

MACARON, the name of a ſort of vermicelli, a paſte made of flour and water, and formed in the ſhape of the barrel of a large quill, or the guts of ſmall fowls.

MACARONIC, or MACARONIAN, a kind of burleſque poetry; conſiſting of a jumble of words of different languages, with words of the vulgar tongue latiniſed, and Latin words modernized.

Macaronic, among the Italians, as has been obſerved by Caelius Rhodiginus, ſignifies a coarſe clowniſh man: and becauſe this kind of poetry, being patched out of ſeveral languages, and full of extravagant words, is not ſo polite and ſmooth as thoſe of Virgil, &c. the Italians, among whom it had its riſe, gave it the name of *Macaronian* or *Macaronic* poetry. Others chooſe to derive it *a Macaronibus*, from *Macaroons*, a kind of confection made of meal not boulted, ſweet-almonds, ſugar, and the whites of eggs: accounted a great dainty among the country people in Italy; which from their being compoſed of various ingredients occaſioned this kind of poetry, which conſiſts of Latin, Italian, Spaniſh, French, Engliſh, &c. to be called by their name.

Theoph. Folingius, a Benedictine monk of Mantua, was the firſt who invented, or at leaſt cultivated, this kind of verſe: for though we have *Macaronea Aſtinianenſis* in a very old letter, beginning, "Eſt author Typhis Leonicus atque Patanſus;" yet it ſeems to have been the work of Guarinus Capellus Sarſinas, who, in the year 1526, printed ſix books of *Macaronic* poetry, in Cabrinum Gagamonæ Regem: but as both theſe came out after the firſt edition of Folingius, which was publiſhed under the name of Merlinus Cocca jus in 1520, ſo they were likewiſe much inferior to his both in the ſtyle, invention, and epiſodes, wherewith he haſteuriched the hiſtory of Baldus; which make the ſubject of his poem. The famous Rabelais firſt transferred the *Macaronic* ſtyle out of the Italian verſe into French proſe, and on the model thereof formed ſome of the beſt things in his Pantagruel.

We have ſcarce any thing in Engliſh in the *Macaronian* way, except ſome little looſe pieces collected in Camden's remains; which is no diſcredit to our authors: for one may ſay of ſuch pieces in general,

Turpe eſt difficiles habere nugas,
Et ſtultus labor eſt ineptiarum.

But the Germans and Netherlanders have had their *Macaronic* poets; witneſs the Certamen catholicum cum Calviniſtis, of one Martinius Hamconius Friſius, which contains about twelve hundred verſes, all the words whereof begin with the letter C.

MACAROON. See MACARONIC.

MACASSAR *poison*, in *Natural History*, called *upas*, in the Macassar and Malayan tongue, is the gum of a certain tree, shining, brittle, black, and every way like stone-pitch, growing in the island Celebes, in the South Seas; with which all the natives arm themselves in travel, having a long hollow trunk of a hard red-wood like brasil, accurately bored, and at one end is fixed a large lance-blade of iron. Then they make a small arrow, very strait, and somewhat bigger than a large wheaten straw: at one end they fix it into a round piece of white, light, soft wood, like cork, about the length of the little finger, just fit for the bore of the trunk, to pass clear by the force of one's breath, and to fill it so exactly, that the air may not pass by, but against it, in order to carry it with the greater force. At the other end they fix it either in a small fish-tooth for that purpose, or make a blade of wood of the bigness of the point of a lancet, about three-quarters of an inch long, and making a little notch in the end of the arrow, they strike it firm therein, which they anoint with poison. The poisonous gum, when gathered, is put into hollow bamboos or canes, stopped up very close, and thus brought to *Macassar*. When they fit it for use, they take a piece of smooth turtle-shell, and a stick cut flat and smooth at the end; then they take green galangal root, grate it, and with the addition of a little fair water, press the juice into a clean china dish; then with a knife, scraping a little of the poison upon the shell, dip the end of the stick in the forementioned liquor, and with that dissolve the poison, to the consistence of a syrup: when this is done, they anoint the fish-tooth of wooden-blade with the same stick and lay them in the sun, so that it may be baked hard. The pointed arrows thus prepared are put in hollow bamboos, close shut, and in this state they retain their virtue for a month. Loch's Hist. of the Royal Society, vol. ii. p. 440.

MACAW, MACCAW, or MACAO, in *Ornithology*, the name of a large species of *parrot*, distinguished also by the length of its tail. There are three different species of this bird brought over into Europe, which not only differ in size and other particulars, but also in colour. The first is the largest, and is finely variegated with blue and yellow; the second is somewhat smaller than that, and is principally red and yellow; and the third is red and blue. It is not uncommon also to see the *macaws* perfectly white, and it is to that particular colour we give the name of *cockatoos*; though with some it is made the synonymous name of all the *macaw* tribe.

MACAW-*tree*. See PALM-*tree*.

MACCABEES, two apocryphal books of scripture, containing the history of Judas and his brothers, and their wars against the Syrian kings in defence of their religion and liberties, so called from Judas Maccabæus, surnamed *Maccabæus*, as some say from the word מכבי, formed of the initials of מי כמכה באלם יהוה, q. d. *Who is like unto thee, O Lord, among the Gods*; which was the motto of his standard; whence those who fought under his standard were called *Maccabees*, and the name was generally applied to all who suffered in the cause of the true religion, under the Egyptian or Syrian kings. The first book of the *Maccabees* is an excellent history, and comes nearest to the style and manner of the sacred historians of any extant. It was written originally in the Chaldee language, of the Jerusalem dialect, and was extant in this language in the time of Jerom. From the Chaldee it was translated into Greek, from the Greek into Latin. It is supposed to have been written by John Hyrcanus, the son of Simon, who was prince and high priest of the Jews near thirty years, and began his government at the time where this history ends. It contains the history of forty years, from the reign of Antiochus Epiphanes to the death of Simon the high priest; that is, from the year of the world 3829 to the year 3869; 131 years before Christ. The second book of the *Maccabees* begins with two epistles sent from the Jews of Jerusalem to the Jews of Egypt and Alexandria; to exhort them to observe the feast of the dedication of the new altar erected by Judas, on his purifying the temple. The first was written in the 169th year of the æra of the Seleucidæ, i. e. before Christ 144; and the second in the 188th year of the same æra, or 125 before Christ; and both appear to be spurious. After these epistles follows the preface of the author to his history, which is an abridgment of a larger work, composed by one Jason, a Jew of Cyrene, who wrote in Greek the history of Judas *Maccabæus*, and his brethren, and the wars against Antiochus Epiphanes, and Eupator his son. This second book does not, by any means, equal the accuracy and excellency of the first. It contains a history of about fifteen years, from the execution of Heliodorus's commission, who was sent by Seleucus to fetch away the treasures of the temple, to the victory obtained by Judas *Maccabæus* over Nicanor; that is from the year of the world 3828 to the year 3843, 147 years before Christ.

There are in the Polyglot Bibles, both of Paris and London, Syriac versions of both these books; but they, as well as the English versions which we have among the apocryphal writers in our Bibles, are derived from the Greek. There is also a third book of the *Maccabees*, containing the history of the persecution of Ptolemy Philopator against the Jews in Egypt, and their sufferings under it; and seems to have been written by some Alexandrian Jew in the Greek language, not long after the time of Siracides. It is in most of the ancient manuscript copies of the Greek Septuagint, particularly in the Alexandrian and Vatican, but was never inserted into the vulgar Latin version of the Bible, nor consequently into any of our English copies. Moreover, Josephus's history of the martyrs that suffered under Antiochus Epiphanes, is found in some manuscript Greek Bibles, under the name of the fourth book of the *Maccabees*.

MACE, *macis*, is a pretty thick, tough, unctuous membrane, reticulat or variously chapt, of a lively reddish yellow colour, approaching to that of saffron, enveloping the shell of the fruit, whose kernel is the NUTMEG. The *mace*, when fresh, is of a blood-red colour, and acquires its yellow hue in drying. It is dried in the sun upon hurdles fixed above one another, and then, as it is said, sprinkled with sea-water, to prevent its crumbling in carriage.

Mace has a pleasant aromatic smell, and a warm, bitterish, moderately pungent taste; it is a thin and flat membranaceous substance, of an oleaginous nature, and of a yellowish colour. We meet with it in flakes of an inch or more in length, which are divided into a multitude of irregular ramifications; it is of an extremely smooth surface, and of a tolerably close texture, yet friable, and very easily cut to pieces. It is of an extremely fragrant, aromatic, and agreeable smell, and of a pleasant, but acrid and oleaginous taste; it is to be chosen new, not *dry*, and of a fragrant smell, tough, oleaginous, and of a good yellow. The people who collect the nutmegs first cut it open, and throw away the pulpy substance, or external coat; they then see the *mace* covering the nutmegs, wrapping itself every way round its outer woody shell. The *mace* is at this time of a red colour; they take it carefully off from the nutmeg, and lay it in the sun for the whole day. In this little its colour, from a strong blood-red, becomes dusky; it is after this carried to another place, where the sun has less power, and there exposed again to its rays, the few hours they reach thither. By this means it dries gently, and remains tough, and retains its fragrancy and colour in a great degree; if it were dried more hastily, it would be whitish, brittle, and would lose much of its smell; after this it is slightly sprinkled over with sea-water, and then put up into bales, in which it is pressed down firm and close, by way of preserving its fragrance and consistence.

It is of an astringent and drying nature, and is used as a corrector in cordiac and cathartic compositions. In its general qualities it is nearly similar to the nutmeg; the principal difference consists in the *mace* being much warmer, more bitterish, less unctuous, and fitting easier on weak stomachs: in its yielding by expression a more fluid oil, and in distillation with water a more subtile volatile one. Lewis's Mat. Med.

MACE, *oil of*, is a kind of sebaceous matter, said to be expressed from the nutmeg, and appearing to be a mixture of the gross sebaceous matter of the nutmeg, with a little of the essential or aromatic oil; both which may be perfectly separated from one another by maceration or digestion in rectified spirit, or by distillation with water. The best sort of this oil is brought from the East Indies in stone jars, and is somewhat soft, of a yellow colour, and of a strong agreeable smell, much resembling that of the nutmeg itself. There is another sort brought from Holland in solid masses, generally flat, and of a square figure, of a paler colour, and much weaker smell. Lewis.

MACE, *reed*, in *Botany*. See TYPHA.

MACEDONIAN *kingdom*, in *Ancient History*, one of the four kingdoms into which the EMPIRE of Alexander was divided after his death. This kingdom, under Perseus, who was overcome and taken by Æmilius, and carried in triumph to Rome, where he died in prison, was reduced to the form of a Roman province. The other three, viz. the Asiatic, Syrian, and Egyptian kingdoms, flourished for a considerable time under their own kings, but were at last compelled to receive the Roman yoke.

MACEDONIAN *year*. See YEAR.

MACEDONIANS, in *Ecclesiastical History*, the followers of Macedonius, bishop of Constantinople, who, through the influence of the Eunomians, was deposed by the council of Constantinople in 360, and sent into exile. He considered the Holy Ghost as a divine energy diffused throughout the universe, and not as a person distinct from the Father and the Son. The sect of *Macedonians* was crushed before it had arrived at its full maturity, by the

the council assembled by Theodosius in 381, at Constantinople. See SEMI-ARIANS.

MACER. The Grecian *macer* is brought from Barbary; and the part in use is the thick yellow bark, which has a very astringent taste, and is said by Dioscorides to be good for spitting of blood, the dysentery, and fluxes. See SIMAROUBA.

MACERATION, in *Pharmacy*, the operation of dissolving a solid body by means of water, or some other liquor.

In this sense, the word amounts to much the same with LIQUEFACTION, or liquation.

MACERATION is also used for the infusing a body in any menstruous fluid, in order to a solution of its principles, whether with or without fire.

In which sense, *maceration* amounts to much the same with DIGESTION.

Others restrain *maceration* to that particular kind of digestion, which is performed in thick substances, as when, having mixed roses with fat to make *unguent. rosatum*, the mixture is exposed for some days to the sun, that the virtue of the roses may be the better communicated to the fat.

MACERONE, in *Botany*, a name given by some authors to the great *hipposelinum*, or herb alexanders, or ALEXANDERS.

MACHA *nuces*, a kind of African CALABASH. It is the fruit of a very large tree which grows in Africa, and the American islands. When this fruit is ripe, the pulp has a flourish taste, with a little astringency: it is delicious in hot countries; and they prepare a liquor of it, which they use instead of lemonade, to cool and refresh themselves, and give it to sick persons under a looseness. The pulp, dried, tastes as well as the spiced bread of Rheims. The slaves make a kind of thick gruel with this pulp and water; it is of an absorbent quality. The African women use the pulp instead of rennet, for curdling their milk.

The seeds of this fruit are as big as small pine-apple kernels, kidney-shaped, of a chestnut-colour, and inclosing an almond far more delicious than our sweet almonds.

MACHÆRION, a word used by chirurgical writers as the name of an instrument of the nature of the incision knife. It is also sometimes used to express an incision; and by the auspices of old it was applied to some peculiar part of the liver of animals, from which they presaged events.

MACHERA *lapis*, in *Natural History*, the name of a stone of a ferrugineous colour, frequent on mount Berecynthus in Phrygia. Plutarch, and many other grave writers, relate, that if any person found this stone, and took it up at the time of the celebration of the feasts of Cybele, he instantly was seized with madness.

MACHIAVELISM, in *Literary History*, is a species of detestable politics, which may be defined in few words, the art of reigning tyrannically, the principles of which are inculcated in the works of Machiavel, a native of Florence, and particularly in his treatise, entitled the Prince. M. de Wicquefort observes, concerning the character of this writer: Machiavel says almost every where what princes do, and not what they ought to do. To the same purpose the chancellor Bacon remarks: *Est quod gratiæ agamus Machiavello et hujus modi scriptoribus qui aperte et indissimulanter proferunt quid homines facere soleant non quid debeant.* Machiavel was secretary, and afterwards hiftoriographer to the republic of Florence. He was put to the rack upon the suspicion of being concerned in a confederacy against the house of Medicis; but he endured the torments of it, without making any confession. He was so much an enemy to religion as to found politics; and is said to have died, in the year 1530, uttering profane jests and blasphemies. Bayle.

MACHINE, *machina*, in general, signifies any thing that serves to augment, or to regulate moving powers: or it is any body destined to produce motion, so as to save either time or force.

The word comes from the Greek μηχανη, *machina, invention, art.* And hence, in ſtrictneſs, a *machine* is something that conſiſts more in art and invention, than in the ſtrength and ſolidity of the materials; and for this reaſon it is that the inventors of *machines* are called *inventors.*

MACHINES, *ſimple*, are thoſe otherwiſe called MECHANICAL *powers.* There are ſix ſimple *machines*, to which all others may be reduced; viz. the BALANCE, LEVER, WHEEL, PULLEY, WEDGE, and SCREW.

The ſimple *machines*, or mechanical powers, according to their different ſtructure, ſerve for different purpoſes; and it is the buſineſs of the ſkilful mechaniſt to chooſe them, or combine them, in the manner that may be beſt adapted to produce the effect required, by the power which he is poſſeſſed of, and at the leaſt expence. The lever can be employed to raiſe weights a little way only, unleſs the engine itſelf be moved; as, for inſtance, to raiſe ſtones out of their beds in quarries. But the axis and wheel may ſerve for raiſing weights from the greateſt depths. Pullies being eaſily carried, are therefore much employed in ſhips. The wedge is excellent for ſeparating the parts of bodies; and the ſcrew for compreſſing or ſqueezing them together; and its great friction is even ſometimes of uſe, to preſerve the effect already produced by it. The ſtrength of the *machine*, and of its parts, muſt be proportioned to the effects which are to be produced by it. Thus, when the center of motion is placed between the power and the weight, it muſt ſuſtain the ſum of their efforts; a ſmall balance, therefore, ought not to be employed for weighing great weights; for theſe diſorder its ſtructure, and render it unfit for ſerving that purpoſe with accuracy. Neither are great *machines* proper for producing ſmall effects. It were to be wiſhed, that we had a detail of all theſe things drawn up by ſome ſkilful and experienced mechaniſt.

From theſe ſimple *machines*, compounded ones are formed by various combinations, and ſerve for different purpoſes; in all which the ſame general laws take place; and particularly this, that the power and weight ſuſtain each other, when they are in the inverſe proportion of the velocities which they would have in the directions wherein they act, if they were put in motion.

But in practice the friction of *machines* is to be conſidered, without allowing for which we ſhall often find ourſelves at a loſs. See FRICTION.

Accurate deſcriptions and draughts of *machines* would be a very curious and uſeful work. But to make a collection of this kind as advantageous as poſſible, it ſhould, beſides the deſcriptions of *machines*, contain an analyſis of them; pointing out their advantages and diſadvantages; the reaſons of the conſtructions; and the general problems, implied in theſe conſtructions, with their ſolutions, ſhould be extracted. None of theſe things have as yet been done, in a complete and ſatisfactory manner, in any treatiſe of this kind. However, many curious particulars may be gathered from Strada, Beſſon, Beroaldus, Auguſtinus de Ramellis, Boeckler, Leupold, Beyer, Limpergh, Van Zyl, Perault, and others; a ſhort account of whoſe works we find in Wolfii Commentatio de præcipuis ſcriptis Mathematicis. Elem. Matheſ. Univ. tom. v. p. 84. ſeq. To theſe muſt be added, monſieur Belidor's Architecture Hydraulique, and Dr. Deſaguliers's Courſe of Experimental Philoſophy. The Royal Academy of Sciences at Paris have alſo given us a collection of *machines* and inventions approved of by them. This work, publiſhed by monſieur Gallon, conſiſts of ſix volumes in quarto, containing engraved draughts of the *machines*, with their deſcriptions annexed. But a complete inſtitution of practical mechanics is ſtill wanting.

MACHINE, *compound*, is that which is compoſed of ſeveral ſimple ones combined together.

The number of compound *machines* is now almoſt infinite; and yet the ancients ſeem to have outdone the moderns in this reſpect; their *machines* of war, architecture, &c. being deſcribed as vaſtly ſuperior to our's.

MACHINE, *architectonical*, is an aſſemblage of pieces of wood ſo diſpoſed, as that, by means of ropes and pulleys, a ſmall number of men may raiſe vaſt loads, and lay them in their places. Such are cranes, &c.

It is hard to conceive what ſort of *machines* the ancients muſt have uſed to raiſe thoſe immenſe ſtones found in ſome of the antique buildings.

MACHINES, *blowing*. See BELLOWS.

MACHINE, *electrical*. See ELECTRICAL *machine*.

MACHINE, *wind*. See ANEMOMETER, and WIND-*machine*.

MACHINE, *water*, or *hydraulic*, is either uſed to ſignify a ſimple *machine*, ſerving to conduct or raiſe water; as a ſluice, pump, &c. or ſeveral of theſe acting together, to produce ſome extraordinary effect; as the

MACHINE *of Marli*. See MARLI. See alſo FIRE-*engine*, and STEAM-*engine*, and WATER-*works*.

MACHINES, *military*, among the *Ancients*, were of three kinds: the firſt ſerving to launch arrows, as the ſcorpion; or javelins, as the catapulta; or ſtones, as the balliſta; or fiery darts, as the pyrabolus: the ſecond ſerving to beat down walls, as the battering ram and terebra; and the third to ſhelter thoſe who approach the enemy's wall; as the tortoiſe or teſtudo, the vinea, and the towers of wood. See SCORPION, ARIES, &c.

The *machines of war* now in uſe, conſiſt in artillery, bombs, petards, &c.

MACHINE, in *Dramatic Poetry*, is when the poet brings ſome divinity or ſupernatural being upon the ſtage, to perform ſome exploit, or ſolve ſome difficulty, out of the reach of human power.

The *machines* of the drama are gods, angels, ghoſts, &c. They are ſo called from the *machines* or contrivances by which they are repreſented upon the ſtage, and afterwards removed again.

Hence the uſe of the word *machine* has alſo paſſed into

epic poem; though the reason of its name be there wanting. It denotes, in both cases, the intervention or ministry of some divinity: but as the occasion of *machines* in the one and the other is somewhat different, the rules and laws of managing them are different likewise.

The ancient dramatic poets never brought any *machine* on the stage, but where there was an absolute necessity for the presence of a god; and they were generally laughed at for suffering themselves to be reduced to such a necessity. Accordingly, Ariſtotle lays it down as an expreſs law, that the unravelling of the piece ſhould ariſe from the fable itſelf, and not from any foreign *machine*, as in the Medea. Horace is ſomething leſs ſevere, and contents himſelf with ſaying, that the gods ſhould never appear, unleſs where the *nodus*, or knot, is worthy of their preſence; *Nec deus intersit, niſi dignus vindice nodus — inciderit.* But it is quite otherwiſe with the epopea; in that there muſt be *machines* every where, and in every part. Homer and Virgil do nothing without them. Petronius, with his uſual fire, maintains, that the poet ſhould deal more with the gods than with men; that he ſhould every-where leave marks of his prophetic raptures, and of the divine fury that poſſeſſes him; that his thoughts ſhould be all full of fables, that is of allegories and figures: in fine, he will have a poem diſtinguiſhed from a hiſtory in all its parts; not ſo much by the verſes, as by that poetical fury, which expreſſes itſelf wholly by allegories; and does nothing but by *machines*, or the miniſtry of the gods. A poet, therefore, muſt leave it to the hiſtorian to ſay, that a fleet was diſperſed by a ſtorm, and driven to foreign theres; and muſt himſelf ſay, with Virgil, that Juno went to ſeek Æolus; and that this god, at her requeſt, turned the winds looſe againſt the Trojans: he muſt leave the hiſtorian to write, that a young prince behaved himſelf with a great deal of prudence and diſcretion on all occaſions; and muſt ſay, with Homer, that Minerva led him by the hand in all his enterprizes: let an hiſtorian ſay, that Agamemnon, quarelling with Achilles, hath a mind to throw him, though miſtakenly, that he can take Troy without his aſſiſtance; the poet muſt ſay, that Thetis, piqued at the affront her ſon had received, flies up to heaven, there to demand vengeance of Jupiter: and that this god, to ſatisfy her, ſends the god Somnus, or Sleep, to Agamemnon, to deceive him, and make him believe that he ſhall take Troy that day.

It is thus that the epic poets uſed *machines* in all parts of their works; in the Iliad, Odyſſey, and Æneid, the propoſition mentions them; the invocation is addreſſed to them; and the narration is full of them: they are the cauſes of actions; they make the knots; and at laſt they unravel them. This laſt circumſtance is what Ariſtotle forbids in the drama; but it is what Homer and Virgil have both practiſed in the epopea. Thus Minerva flights for Ulyſſes againſt Penelope's lovers; helps him to deſtroy them; and, the next day, herſelf makes the peace between Ulyſſes and the Ithacans; which cloſes the Odyſſey. The uſe of *machines*, in the epic poem is, on ſome accounts, entirely oppoſite to what Horace preſcribes for the theatre. In tragedy, that critic will never have them uſed without an abſolute neceſſity, whereas, in the epopea, they ſhould never be uſed, but where they may be to well let alone; and where the action appears as if it did not neceſſarily require them. How many gods and *machines* does Virgil implore to raiſe the ſtorm that drives Æneas into Carthage; which yet might eaſily have happened in the ordinary courſe of nature.

In Milton's Paradiſe Loſt, moſt of the actors are ſupernatural perſonages; and in Voltaire's Henriade, the poet has made excellent uſe of St. Louis.

Machines, in the epic poem, therefore, are not contrivances of the poet, to recover himſelf after he has made a falſe ſtep, nor to ſolve any difficulty peculiar to ſome part of the poem; but it is the preſence of a divinity, and ſome ſupernatural and extraordinary action, which the poet inſerts in moſt of the incidents of his work, to render it more majeſtic and admirable, and to train up his readers to piety and virtue. This mixture ſhould always be ſo managed, as that the *machine* may be retrenched, without retrenching any thing from the action. As to the manner in which the *machines* are to act; it may be obſerved, that in the old mythology, there are gods both good, bad, and indifferent; and that our paſſions may be converted into ſo many allegorial divinities: ſo that every thing, both good and bad in a poem, may be attributed to theſe *machines*, and may be tranſacted by them. They do not, however, always act in the ſame manner; ſometimes they act without appearing, and by ſimple inſpirations, which have nothing in them extraordinary or miraculous; as when we ſay, the devil ſuggeſted ſuch a thought, &c. The ſecond manner of acting is entirely miraculous; as when a divinity preſents itſelf viſible before men, ſo as to be known by them; or when they diſguiſe themſelves under ſome human form without diſcovering themſelves. The third manner partakes of each of the two, and conſiſts in oracles, dreams, and extraordinary inſpirations: all which Boſſu calls *demi-machines*.

All theſe manners ought to be ſo managed, as to carry a verſimilitude: and though verſimilitude be of a vaſt extent in *machines*, as being founded on the divine power, yet it has its bounds.

MACHUI, an inſtrument of muſic among the Hebrews: Kircher apprehends that the name was given to two kinds of inſtruments, one of the ſtringed and the other of the pulſatile kind. That of the former ſort had ſix chords, and is repreſented *Tom. Muſurg. fig.* 4. Though there is great reaſon to doubt whether an inſtrument requiring the aid of the hair-bow, and ſo much reſembling the viol, be ſo ancient. The ſecond kind was of a circular form, (ſee *fig.* 5.) made of metal, and either hung round with little bells, or furniſhed with iron rings, ſuſpended on a rod or bar that paſſed acroſs the circle. Kircher ſuppoſes that it was moved to and fro by a handle fixed to it, and thus emitted a melancholy kind of murmur.

MACHUS, in *Natural Hiſtory*, a name uſed by Pliny and ſome of the old authors, for the ELK, and alſo for the REIN-DEER.

MACKREL, *ſcomber*, in *Ichthyology*, a well known ſea-fiſh of the ſcomber kind: the noſe is taper and ſharp-pointed; the eyes large; the jaws of an equal length; and the teeth ſmall, but numerous; the body is a little compreſſed on the ſides; towards the tail it grows very ſlender, and a little angular; the firſt dorſal fin is placed a little behind the pectoral fin, is triangular, and conſiſts of nine or ten ſtiff rays; the ſecond lies at a diſtance from the other, and has twelve ſoft rays; the pectoral, twenty; the ventral, ſix; and at the baſe of the anal fin is a ſtrong ſpine; between the laſt dorſal fin and the tail are five ſmall fins, and the ſame number between the anal fin and the tail; the tail is broad and ſemilunar; the colour of the back and ſides above the lateral line is a fine green, varied with blue, marked with black lines, pointing downwards; beneath the line, the ſides and belly are of a ſilvery colour. In the ſpring, the eyes of the *mackrel* are almoſt covered with a white film, which grows in winter, during which period they are half blind, and is caſt in the beginning of ſummer. This fiſh was in high eſteem among the Romans, becauſe it furniſhed the precious GARUM. The beſt time of taking *mackrel* is during a freſh gale of wind, which it thence called the *mackrel* gale. See *Mackrel* FISHERY. Pennant.

MACKREL, *horſe*, *ſcomber trachurus*, of Linnæus, in *Ichthyology*, a name given by us to a peculiar ſpecies of *mackrel*, called alſo in Cornwall a ſcad. It is the *trachurus* of authors in general. Bellonius calls it the *lacertus*, and the old Greek writers, as Ariſtotle and the reſt, the *ſaurus*. Artedi diſtinguiſhes it by the name of the *ſcomber*, or *mackrel*, with the lateral lines acuſtuated, and with thirty rays in the pinnæ ani. This fiſh is firm and well taſted, and has the flavour of *mackrel*.

MACROCEPHALUS, *Macrocephalus*, compounded of μακρος, *great*, and κεφαλη, *head*, denotes a perſon with a head larger or longer than the common ſize.

Macrocephali, or *long heads*, is a name given to a certain people, who, according to the accounts of authors, were famous for the unſeemly length of their heads: yet cuſtom ſo far habituated them to it, that inſtead of looking on it as a deformity, they eſteemed it a beauty, and as ſoon as the child was born, moulded and faſhioned its head in their hands to as great a length as poſſible, and afterwards uſed all ſuch rollers and bandages as might ſeem moſt likely to determine its growing long.

MACROCERCI, the name eſtabliſhed by Dr. Hill for a large genus of animalcules, diſtinguiſhed from all others by having tails longer than their bodies. See ANIMALCULE.

MACRONEMUM, in *Botany*, a genus of the *pentandria monogynia* claſs: the characters are, that the flower is bell-ſhaped, the fruit is a double-celled capſule, and the ſeed imbricated. There is only one ſpecies.

MACROCOLUM, or MACROCOLLUM, formed of μακρος, *large*, and κολλα, *glue*, among the Romans, the largeſt kind of paper then in uſe. It meaſured ſixteen inches, and frequently two feet.

MACROCOSM, *Macrocoſmus*, compounded of μακρος, *long*, *large*; and κοσμος, *world*, denotes the great world, that is, the univerſe.

In which ſenſe it ſtands contradiſtinguiſhed from MICROCOSM, a term uſed to expreſs man.

MACROLOGY, *Macrologia*, formed of μακρος, *long*, and and λογος, *diſcourſe*, in *Rhetoric*, a redundant, or too copious ſtyle; an example of which we have in Livy. lib. viii. *Legati non impetrato pace, retro domum, unde venerant abierunt.*

The too copious is equally subject to obscurity with the too concise style, and consequently ought to be avoided. See BRACHYLOGY, DICTION, and STYLE.

MACROPEDIUM, the *long-legs*, a name given by some writers in natural history, to the common TIPULA.

MACROPIPER, a name given by authors to the *piper longum*, or long pepper.

MACROPNUS, formed of μακρος, *long*, and πνευ, *breath*, a word used by Hippocrates, and other old writers in medicine, to signify a person who fetches his breath at long intervals. It is used in opposition to *brachypnus*, or short-breathed.

MACROPTERA, derived from μακρος, *long*, and πτερον, *wing*. The hawks of this genus have their wings so long, that when closed they reach to the end of the tail, or nearly so. Of this genus are the bald-buzzard, the kite, the hen-harrier, the honey-buzzard, and the common buzzard, the facre, the jer-falcon, &c.

MACRORYNCHÆ, *long-beaked*, derived from μακρος, *long*, and ρυγχος, *a beak*, in *Zoology*, the character of a large order of the bird kind.

The birds of this order have all of them beaks many times longer than their heads, with oblong noſtrils, and a furrow running from them towards the apex of the beak.

MACROTELOSTYLA, in *Natural Hiſtory*, the name of a genus of cryſtals, which are compoſed of two pyramids joined to the end of a column; both the pyramids, as alſo the column, being hexangular, and the whole body conſequently compoſed of eighteen planes.

The word is derived from the Greek μακρος, *long*, τελειος, *perfect*, and στυλος, a *column*; expreſſing a perfect cryſtal with a long column. See *Tab. of Foſſils, claſs* 3.

There are only three known ſpecies of this genus. Either of the ſorts found with us, are called by the common name of *Corniſh diamonds*. Hill's Hiſt. of Foſſ.

MACROULE, in *Ornithology*, the name given by many to the largeſt ſpecies of coot. It is of a deeper black than the common kind, and has a large bald ſpot on it's head. It is alſo called by ſome *diable de mer*. It is found in Lancaſhire and Scotland. See COOT.

MACUCAQUA, in *Ornithology*, the name of a Braſilian bird of the gallinaceous kind, called alſo by ſome the *gallina ſylveſtris*, or wild hen. It has no tail; but is a very well taſted fowl, and has twice as much fleſh as the European hen; its eggs are ſomewhat larger than the common hen eggs, and of a bluiſh-green colour; it feeds on fruits that fall off the trees, &c. and runs well, but cannot fly high or far, and never is ſeen in the trees. Marcgrave.

MACULÆ, in *Aſtronomy*, dark ſpots appearing on the luminary faces of the ſun, moon, and even ſome of the planets.

In which ſenſe *macula* ſtand contradiſtinguiſhed from FACULÆ.

MACULÆ, *ſolar*, are dark ſpots of an irregular, changeable, figure, obſerved in the face of the ſun, firſt taken notice of by Galileo, 1610, ſoon after he had finiſhed his teleſcope, and afterwards accurately obſerved by Scheiner, Hevelius, Mr. Flamſteed, Caſſini, Kirch, &c. Phil. Tranſ. vol. i. p. 274. vol. liii. p. i. p. 104.

Many of theſe *maculæ* appear to conſiſt of heterogeneous parts; whereof the darker and more denſe are called by Hevelius, nuclei, and are encompaſſed, as it were, with atmoſpheres, ſomewhat raſer, and leſs obſcure; but the figure both of the nuclei, and entire *maculæ*, is variable. In 1643, Hevelius obſerved a ſmall thin *macula*, which, in two days time, grew to ten times its bulk; appearing withal much darker, and with a larger nucleus; and ſuch ſudden mutations are frequent. The nucleus, he obſerved, began to fall ſenſibly before the ſpot diſappeared; and that, before it quite vaniſhed, it broke into four, which, in two days, again reunited. Some *maculæ* have laſted two, three, ten, fifteen, twenty, thirty, but ſeldom forty days; though Kirchius obſerved one in 1681, which remained from April 26th to the 17th of July. The ſpots move over the ſun's diſk with a motion ſomewhat ſlacker near the limb than the centre: that obſerved by Kirchius was twelve days viſible on the ſun's diſk; for fifteen days more it lay behind it, it being the uſual rule to return to the limb whence they departed in twenty-ſeven, ſometimes in twenty-eight days.

Laſtly, it muſt be obſerved, that the *maculæ* contract themſelves nearer the limb, and in the middle of the diſk appear much larger; thoſe often running into one in the diſk, which, in the limb, were ſeparate: that many of them ariſe in the middle of the diſk, and many diſappear in the ſame: and that none of them are obſerved to deviate from their path near the horizon; whereas Hevelius, obſerving Mercury in the ſun near the horizon, found him too low, being thruſt twenty-ſeven ſecounds beneath his former path.

From theſe phenomena we collect, 1. That ſince Mercury's depreſſion below his path ariſes from his parallax, the *maculæ*, having no parallax from the ſun, are nearer him than that planet.

2. That, ſince they ariſe and diſappear in the middle of the ſun's diſk, and undergo various alterations with regard both to bulk, figure, and denſity, they muſt be formed *de novo*, and again diſſolved about the ſun; and hence ſome have inferred, that they are a kind of ſolar clouds, formed out of its exhalations.

3. If they are of this nature, as they riſe over his body, and are ſuſpended at a certain height from it, it appears, from the laws of hydroſtatics, that the ſun muſt be encompaſſed with ſome fluid to drive thoſe exhalations upwards; which fluid muſt be denſer as it is lower, and rarer as higher, like our atmoſphere: and, ſince the *maculæ* diſſolve and diſappear in the very middle of the ſun's diſk, the matter thereof, ſuppoſing them to be ſolar exhalations, muſt fall back again to the ſun; whence there muſt ariſe changes in the ſun's atmoſphere; and, conſequently, in the ſun itſelf.

4. Since the revolution of the *maculæ* round the ſun is very regular, and ſince their diſtance from the ſun is very ſmall, it is not properly the *maculæ* that move round the ſun, but it is himſelf, together with his atmoſphere, wherein the *maculæ* ſwim, that in the ſpace of twenty-ſeven days, twelve hours, twenty minutes, moves round his own axis; and to the ſame fixed ſtar, in twenty-five days, fifteen hours, ſixteen minutes (ſee SUN); and hence it is, that the *maculæ*, being viewed obliquely near the limb, appear narrow and oblong.

5. Since the ſun appears with a circular diſk in every ſituation, his figure, as to ſenſe, muſt be ſpherical.

The magnitude of the ſurface of a ſpot may be eſtimated by the time of its tranſit over a hair in a fixed teleſcope. Galileo reckons ſome ſpots to be larger than all Aſia and Africa put together: but if he had known the ſun's parallax and diſtance, as exactly as we do, he would have found them much larger than the whole ſurface of the earth. For, in 1612, he obſerved a ſpot ſo large as to be plainly viſible to the naked eye; it, therefore, ſubtended an angle at the eye of about a minute. The diameter of the earth, if removed to the ſun, would ſubtend an angle of but about ſeventeen ſecounds. Therefore the diameter of the ſpot was to the diameter of the earth, as ſixty to ſeventeen, or three one-half to one nearly; and conſequently, the ſurface of the ſpot, if circular, to a great circle of the earth, as twelve one-fourth to one, and to the whole ſurface of the earth, as twelve one-fourth to four, or nearly three to one. Gaſſendus obſerved a ſpot whoſe diameter was $\frac{1}{30}$ of the ſun's, and, therefore, ſubtended an angle at the eye of above a minute and a half. Its ſurface was, therefore, above ſix times larger than the whole ſurface of the earth. He tells us, that he ſaw above forty ſpots at once, but did not perceive that the light of the ſun was ſenſibly diminiſhed: nevertheleſs, the paſſages of the ſun mentioned by hiſtorians, after the death of Julius Cæſar, might have been cauſed in this manner, if we admit the fact.

The opinions that have been formed concerning the nature, origin, and ſituation of the ſolar ſpots, have been various: Dr. Wilſon, profeſſor of practical aſtronomy in the univerſity of Glaſgow, by attending particularly to the different phaſes preſented by the umbra, or ſhady zone, of a ſpot of an extraordinary ſize that appeared upon the ſun, in the month of November, 1769, during its progreſs over the ſolar diſc, was led to form a new and ſingular conjecture concerning the nature of theſe appearances; which he ſeems to have afterwards confirmed by repeated obſervations. The reſults of theſe obſervations are, that the ſolar *maculæ* are cavities in the body of the ſun; that the nucleus, as the middle or dark part has been uſually called, is the bottom of the excavation; and that the umbra, or ſhady zone uſually ſurrounding it, is the ſhelving ſides of the cavity. Dr. Wilſon appears not only to have very ſatisfactorily aſcertained the reality of theſe immenſe excavations in the ſun's body, but has pointed out a method of meaſuring the depth of them. He eſtimates, in particular, that the nucleus, or bottom of the large ſpot above mentioned, was not leſs than a ſemidiameter of the earth, or about four thouſand miles, below the level of the ſun's ſurface; while its other dimenſions were of a much larger extent. He obſerved, that when a ſpot, in the middle of the ſun's diſc, where it is ſurrounded equally on all ſides with its umbra, comes near the weſtern limb of the ſun; that part of the umbra, which is next to the ſun's centre gradually diminiſhes in breadth, and at length, when the ſpot reaches within about a minute of the limb, totally diſappears; while the umbra, on the other ſide of it, continues nearly of its former dimenſions. If, after the period of half a revolution, the ſpot appears again, on the oppoſite ſide of the diſc, that part of the umbra, which had before diſappeared, and which is now on the left hand ſide of the nucleus, is now

plainly

plainly to be seen; but the umbra on the other side of the spot, or that which is next to the sun's centre, seems to have vanished in its turn; being hid from the view by the upper edge of the excavation, or by the oblique position of its sloping sides with respect to the eye. As the spot, however, advances on the sun's surface, this umbra, or side of the cavity, comes in sight; at first appearing narrow, but afterwards gradually increasing in breadth, in proportion as the spot moves toward the middle of the disc. These appearances, in particular the gradual diminution and disappearance, as well as the re-appearance and gradual enlargement of the umbra, on the one side or the other of a spot, according as it advances near the western limb, or proceeds onwards from the eastern edge of the sun, are naturally accounted for by Dr. Wilson's supposition, that the umbræ are the sloping sides of a cavity, which will appear under different angles, or of different breadths, or totally disappear, according to their position with respect to the eye of the spectator. These appearances, at least, perfectly resemble the phases that would be exhibited by an excavation in a spherical body, made to revolve on its axis; the bottom of the cavity being painted black, and the sides lightly shaded. From these and other observations it may be inferred, that the body of the sun, at the depth of the nucleus, either emits no light, or emits so little as to appear dark, when seen at the same time, and compared, with that resplendent, and probably, in some degree, fluid substance that covers his surface. This manner of considering these phenomena naturally gives rise to many curious speculations and inquiries. It is natural, for instance, to inquire by what great commotion this refulgent matter is thrown up on all sides, so as to expose to our view the darker part of the sun's body, which was before covered by it? What is the nature of this shining matter? and why, when an excavation is formed in it, is the lustre of this shining substance, which forms the slucking sides of the cavity, so far diminished, as to give the whole the appearance of a shady zone, or darkish atmosphere, surrounding the denuded part of the sun's body? On these and many other subjects, Dr. Wilson has advanced some ingenious conjectures; for which we must refer the curious to the Phil. Transf. vol. lxiv. part i. art. 1. See also some remarks on Dr. Wilson's Theory, by Mr. Woolaston, in the Phil. Transf. vol. lxiv. part. ii. art. 3. p. 332, &c.

MACULÆ, in the *Writers of Medicine*, is used to express all kinds of spots and efflorescences on the skin, with different epithets. Thus, *maculæ pestilentiales*, are the spots or efflorescences, which appear upon the skin in pestilential diseases. *Maculæ hepaticæ* are spots of a brownish red colour, appearing on the skin in many places, from an *obstruction* of the blood, attended with a sort of coagulation. *Maculæ solaticæ*, or vanishing spots, are very common to children, appearing in several parts of their bodies, and very soon disappearing again. *Maculæ maternæ* are the spots or blemishes on children, called *nævi*, and marks from the mother's longing; and *maculæ albæ* are white spots which appear in the cornea of the eye, called by other names, albugo, leucoma, nebula, and nubecula.

MACULA *solis*, a word used by many authors to signify a cataract or suffusion.

MAD-*dog*. See MADNESS.

MAD-*apple*, or, as called by some, the EGG *plant*, *melongena*, in *Botany*. Its characters are these: the flower, which has a permanent empalement of one leaf, deeply cut into five acute segments, has but one petal, which is cut into five parts, and reflexed; it has five awl-shaped stamina; and in the center is situated an oblong germen, which becomes an oval or oblong fruit, with one cell, with a fleshy pulp, filled with compressed roundish seeds. There are four species. Miller.

Linnæus has joined this species, and the LYCOPERSICON of Tournefort, to the *solanum*, or NIGHTSHADE, making them only species of that genus.

This plant is propagated in the gardens of the curious with us; and in Spain, Italy, and Barbary, common in the kitchen-gardens, the fruit of them being frequently eaten there boiled with fat flesh, putting thereto some scraped cheese, and preserving it through the winter with vinegar, honey, or salt pickle. This they esteem of great efficacy to provoke venery. In summer also, when the fruit is just ripe, they eat it fresh dressed, with spices, and other ingredients.

The manner of propagating them with us, is to sow the seeds in March, upon a moderate hot-bed; and when the plants are come up, they are to be thinned by planting them in another hot-bed at about four inches asunder, watering and shading them till they have taken root. They must afterwards have as much air as the season will allow; and in May they must be transplanted into a warm border, setting them at two feet distance every way. About the middle of July the fruit will appear; and if the weather be dry at this time, they must be often watered, which will make the fruit grow large. The fruit ripens in the end of August. Miller.

The apples being much like those of the mandrake, have induced some moderns to suspect this plant to be the male mandrake of Theophrastus; and supposing them to be deadly, to call them *mad-apples*; whereas in reality they excite no symptoms of madness, but are used by the Italians and Spaniards in their sauces and sweetmeats. They have the taste of the citron.

MAD-*water*, among *Miners*, is water that has been drawn from a shaft, or any part of a mine, and returns back again to the same place from whence it was drawn.

MAD-*wort*, *alyssum*, in *Botany*, a genus of the *tetradynamia siliculosa* class. Its characters are these: the flower, which has an oblong four-leaved empalement, that falls away, has four petals in form of a cross, and six stamina, two of which are shorter than the other four, crowned with broad summits; in the center of the flower is situated the oval germen, which becomes a globular, or compressed seed-vessel, containing several compressed seeds. Miller enumerates eight, and Linnæus seventeen species. This plant is said to be aperitive, and good against the bite of a mad dog; being of a very penetrating and diaphoretic nature, and agreeing in other respects with the scurvy-grass.

MAD-*wort*, *German*. See ASPERUGO.

MADDER, *rubia*, in *Botany*, a genus of the *tetrandria monogynia* class. Its characters are these; the empalement of the flower is small, cut into four segments, and sits upon the germen; the flower has one bell-shaped petal, having no tube, but is divided into four parts; it has four awl-shaped stamina, which are shorter than the petals, terminated by single summits, and a twin germen under the flower, supporting a slender style, divided into two parts upward, and crowned by two-headed stigmas; the germen afterward becomes two smooth berries, joined together, each having one roundish seed, with a navel. There are three species.

The culture of that species of *madder*, which is used by the dyers and callico printers, and which grows naturally in the Levant, is an article of considerable advantage to the Dutch, insomuch that at an average of several years past they have received from us more than 180,000*l.* per annum, and might be profecuted here with equal success. The method of cultivating it in Holland is this: in autumn they new plough the land, where the *madder* is to be planted, if it is strong and heavy, laying it up in high ridges, that it may be mellowed by the winter's frosts. In March they plough it again, working it very deep, and laying it in ridges at eighteen inches asunder, and about a foot deep. Then, in the beginning of April, when the *madder* begins to shoot out of the ground, they open the earth about the old roots, and take off all the side shoots, which extend themselves horizontally just under the surface of the ground, preserving as much of the root as may be with them. These they plant immediately on the tops of the new ridges, at about a foot distance from each other; and this they usually do in showery weather, when the plants immediately take root, and require no more water. In these ridges they let the plants remain two seasons, keeping them clear of weeds; and at Michaelmas time, when the leaves are fallen off, they take up the roots, and dry them for the market.

The best land for the culture of *madder* in England is a soft sandy loam, which has been for some years in tillage, with a depth of two and a half or three feet of good earth, free from all weeds. The ground should be ploughed deep before winter, and laid in ridges to mellow; and if it be not too strong, there will be no necessity for ploughing it again, till just before the time of planting the *madder*, when it should be ploughed as deep as possible; and there should be men following the plough in the furrows, who should dig a full spit below the bottom of the furrow, and turn it up on the top. The best time for planting the *madder* in the ground, thus prepared and made level, is about the middle or latter end of April; the young shoots being about two inches above the ground. The shoots should be taken up carefully, so that the roots may be large and unbroken; and if they are in any degree withered by lying out of the ground, they should be set upright in water for a few hours before they are planted. In planting of *madder*, if the roots have been left three years in the ground, the best distance of the rows is three feet; but if they are taken up in two years, they may be two feet asunder; and the distance of the plants in the rows should be one foot, if they are to stand two years, or a foot and a half, if they are to stand three years. Where there is no danger of too much wet in winter, the plants may be set upon the level ground; otherwise they should be planted in ridges, that the wet may drain off. The method of planting is

as follows: when the ground is made smooth, a line is drawn across, to mark out the rows; then, with an iron-shod dibble, holes are made at the proper distances; the depth of these holes should be equal to the length of the roots; and when the plants are put into the holes, the earth should be pressed close to them, in order to secure them from being destroyed by birds. It is most advisable in planting *madder*, never to sow or plant any thing between the rows, but to keep the *madder* quite clean from weeds, or any other kind of vegetable. Some showers of rain in a day or two after the planting will be of considerable service. During the first summer, the only culture which the *madder* requires is that of keeping it clean, by scuffling it over with a Dutch hoe, as soon as the weeds appear; and when the shoots or haulm of the plants decay in autumn, they should be raked off the ground; and the intervals between the rows should be either dug with a spade, or ploughed with a hoeing plough, laying up the earth over the heads of the plants in a roundish ridge. Some have covered the haulm of their *madder* with the earth, to keep the frost out of the ground, in the manner of the Dutch; but this practice is not absolutely necessary in England. In the following spring, before the *madder* begins to shoot, the ground should be raked very smooth, and the weeds destroyed; and in the ensuing summer, care must be taken to keep it clear from weeds; and if it is performed by the hoe-plough, the earth of the intervals should be thrown up against one side of the ridges, which will earth up the roots, and greatly increase their strength; but before the ground of one interval is to be hoed, the haulm of the plants should be turned over to the next adjoining interval, and suffered to lie in this manner for two or three weeks; and then turned back again on those intervals which were hoed, observing first to scuffle the ground; then the alternate intervals should be ploughed in like manner, turning the earth up against the opposite sides of the roots. By this method the intervals will be alternately ploughed, and the plants earthed up, whereby the ground will be kept clean and mellow, which will greatly promote the growth of the roots; and thus the superficial shoots will be subdued, and the principal roots greatly strengthened. In the following autumn the ground should be cleared of the haulm and weeds, and the earth raised in ridges over the roots, as in the preceding year. In the third spring the roots will furnish a great supply of young plants; but, before they appear, the ground should be cleaned and raked smooth; and when the young plants are fit to take off, this should be carefully done, always taking off those which are produced at the greatest distance from the crown of the mother plants. The culture of the *madder* in the third summer must be the same as in the second; but as the roots will be then much stronger, the earth should be hoed up a little higher to them at the times when the ground is cleaned and ploughed; and it will be of service to hoe or plough off the distant superficial roots, when come up in the intervals, in order to strengthen the larger downright roots; and as the haulm will be now very strong and thick, the frequent turning it over from one interval to another will prevent its rotting, and the sun is alternately admitted to each side of the roots, which will much contribute to the growth of the *madder*. As soon as the haulm of the *madder* begins to decay in autumn, the roots may be taken up for use, because the roots have then done growing for that season, and will be less liable to shrink, than if they are dug up when the plants are growing. When the season for digging up the *madder* roots is come, it should be done in the following manner: a deep trench should be dug at one side of the ground next to the first row of *madder*, in order to make a sufficient opening to receive the earth, which must be laid therein in digging up the row of roots; so that it should be at least two feet broad, and two spits and two shovellings deep, and as close as possible to the roots, so that they are not cut or broke; then the rows of roots must be carefully dug up, turning the earth into the fore-mentioned trench. After the principal roots are taken up, there will be many of the long fibres remaining below; and, therefore, in order to get the roots as clean as possible, the whole spot of ground should be dug to the same depth as the first trench; and those who are employed in picking up the roots must follow the diggers, to get them all out to the bottom. This digging will be an excellent preparation of the ground for any succeeding crop. After the roots are taken up, the sooner they are carried to the place of drying, the finer will be their colour; and therefore no more roots should be taken up than can be carried under shelter in the same day; for by lying in heaps, they will heat, and much wet will likewise tend to discolour them. The first place, where the roots should be laid to dry, must be open to admit the air, but covered on the top to keep out the wet: a building like that in which tanners dry their skins, will be very proper for this purpose. They may remain in this situation for three or four days, but the roots should be turned over once or twice, that every part may dry equally; and that the earth which adhered to them may be rubbed off. They should then be carried to the kilns to be further dried; and as there are in most parts of England, kilns already erected for drying of malt and hops, they may be used for drying of *madder*; but if there were VENTILATORS fixed to these kilns, for blowing a sufficient quantity of air through the room, where the *madder* roots are drying, in the manner directed by Dr. Hales, for drying of malt and hops, it would be found a much better method than that which is practised by the Dutch, and save a great expence of fuel. When the outside of the roots has been sufficiently dried in this cold stove or kiln, they should be removed to the threshing floor, which may be the same as in a common barn where corn is thrashed. On this floor, made as clean as possible, the roots should be threshed, in order to beat off their skins or outside covering: this skin, called *mull*, is the worst sort of *madder*, and sold at a very low price: when it is separated from the roots, it is pounded by itself, and afterwards packed up in separate casks, and sold under the name of *mull*. This, however, may be sometimes sold at a price, which will defray the whole expence of drying the crop. After the *mull* is separated from the roots, they must then be removed to the kiln again, and there carefully dried in a greater heat than before: and that the heat may not be too great, the roots should be frequently turned in this stove, the fires properly regulated, and a sufficient quantity of fresh air thrown through the kiln, which will serve to drive out the foul air occasioned by the perspiration of the roots, and thus be useful in preserving their colour. It will be always better to have the heat rather less than too violent; for though the roots may require a longer time to dry with a slow heat, yet the colour will be better. When the roots are properly dried in this stove, they must be carried to the pounding-house, where they must be reduced to powder. Any common bulting will serve for this purpose, provided there be room in it for fixing the requisite apparatus: the back for this purpose should be like those used in Holland, and also the hampers, which are bound round at bottom with thick iron bands, framed like the points of a star; for if the surface of the hampers be smooth and even, the *madder* will adhere to them so closely as to render it impossible to pulverise the roots properly. The hampers may be so contrived as to be worked by water, where there is convenience, or perhaps by wind; but in Holland it is done by horses. Miller.

It appears from the calculations of another writer, that, supposing the land to be worth 40*s.* per acre, and excluding the original price of the plants, the whole expence of cultivating it with *madder*, is 16*l.* 18*s.* 2*d.* and that the produce of it is 52*l.* 12*s.* 2*d.* so that the clear profit is 36*l.* 14*s.*

Persons stealing or destroying *madder* roots are liable to satisfaction for damages, at the discretion of the justice, for the first offence, or commitment to the house of correction for one month, or whipping; and for the second offence, commitment to the house of correction for three months: provided that the prosecution be commenced within thirty days. 31 Geo. II. c. 35.

The root of the common *madder* cultivated for the use of the dyers, is an excellent aperient and diuretic. When taken internally it tinges the urine red. It is prescribed with great success in obstructions of the liver and spleen, in suppressions of the menses and urine, and in dropsies, jaundices, and cachexies. It is also recommended as a vulnerary, and said to be peculiarly excellent in the dissolving coagulated blood. The college of Edinburgh makes it an ingredient in the ictetic decoction, which is prepared by boiling an ounce of *madder*, the same quantity of turmeric, and the same quantity of the roots and leaves of celandine, in three pints of water to a quart, to which, when strained and cooled, the juice of two hundred millepedes is added: a quarter of a pint of this liquor is taken twice a day, or oftener. The dyers prepare a red colour with it, and use it also as a first tint for several others.

It impregnates water with a dull red colour, and spirit of wine with a deep bright red. Wool, previously boiled in a solution of alum and tartar, receives from a hot decoction of *madder* and tartar, a very durable, but not a very beautiful red colour. M. Margraaf (Berlin Mem. 1774) shews how a very durable lake, of a fine red colour, fit for the purposes of painting, may be obtained from *madder*. The process is as follows: take two ounces of the purest Roman alum, and dissolve it in three (French) quarts of distilled water that has boiled, and in a clean glazed pot. Set the pot on the fire, and when the water begins to boil, withdraw it, and add to it

two ounces of the beſt Dutch *madder*. Boil the mixture once or twice; then remove it from the fire, and filtrate it through a double filtre of paper not coloured. Let the filtrated liquor ſtand for a night to ſettle; and pour off the clear liquor into the glazed pot, well cleaned. Make the liquor hot, and add to it gradually a clear ſolution of ſalt of tartar in water, till all the *madder* is precipitated; filtrate the miſture, and upon the red precipitate which remains upon the filtre, pour boiling diſtilled water, till the water no longer acquires a ſaline taſte; the red lake is then to be gently dried. The colour of this precipitate is deep; but if two parts of *madder* be uſed to one part of alum, the colour will be ſtill deeper: one part of *madder* and four parts of alum produce a beautiful roſe-colour. Mr. John Belchier ſhewed to the Royal Society the bones of hogs which were become red, by their feeding on bran that had been boiled with printed calicoes, which had been ſtained with preparations of iron, alum, ſugar of lead, and that had an infuſion of *madder-root*, to fix the colours. By feeding a cock fifteen days on fig-duſt, with a little *madder-root*, all his bones became alſo red. Phil. Tranſ. N° 457.

Mr. Hamel du Monceau verified Mr. Belchier's experiments, and obſerved, that except the villous coat of the ſtomach and inteſtines, the capſula of the cryſtalline and vitreous humours of the eyes, and ſome very hard bony tendons, and the bones; no other part had any tincture of the *madder*. The moſt ſolid bones were moſt tinged, and all the red ones were larger, more ſpungy, and eaſily broken; nor did they unite ſo well, when broken, as white bones. Some young animals had their bones tinged in three days. The red colour went gradually off, when the creatures forbore to take the *madder* for food, which proved unhealthy, for they began to languiſh ſoon, and died with it. Vegetables did not take the red colour when they were planted in *madder*; and none of the other dyes, with which he fed animals, had any ſuch effect of tinging their bones, as the *madder* had. Mr. du Hamel, having mixed *madder* with the food of a pig for ſome time, and then kept away the *madder* an equal time, found, upon ſawing the bones through, that their interior lamin æ were red, while the exterior were white: and having fed another pig ſix weeks with *madder*, then kept it out of its food as long, and then mixed it other ſix weeks; upon ſawing the bones, they were compoſed of three layers, whereof the external and internal were red, the middle one was white. Mem. de L'Acad. des Scienc. 1739. & Phil. Tranſ. N° 457. § 4. Med. Eſſ. Edinb. Abr. vol. ii. p. 477.

MADDER, *little field*, *Sherardia*, in *Botany*, a genus of the *tetrandria monogynia* claſs. Its characters are theſe: the flower has a ſmall permanent empalement ſitting upon the germen; it has one long tubulous petal, cut into four plain acute parts at the brim; it has four ſtamina, ſituated on the top of the tube; terminated by ſingle ſummits, and an oblong twin germen below the flower, ſupporting a ſlender biſid ſtyle, crowned by two-headed ſtigmas; the germen afterwards becomes an oblong fruit, containing two oblong ſeeds; which are ſeparated. Miller reckons two, and Linnæus three ſpecies.

MADDER, *petty*, in *Botany*. See CRUCIANELLA.

MADERAM-*pulli*, in *Botany*, a name uſed by ſome authors for the tree whoſe fruit is the tamarind of the ſhops.

MADIC, a word uſed by ſome medical writers for buttermilk.

MADISTERIUM, *Madiſterium*, a name given by the Greeks to an inſtrument intended to keep the ſkin ſmooth, by eradicating the hairs.

MAD-HOUSE. By 14 Geo. III. c. 49. enacted to be in force for five years, and by 19 Geo. III. c. 15. which continues it for ſeven years farther, no perſon, on pain of 500*l.* ſhall entertain or confine, in any houſe kept for the reception of LUNATICS, more than one lunatic at a time, without a licence to be granted yearly by five commiſſioners, annually elected by the colleges of phyſicians, within London and Weſtminſter, and ſeven miles thereof, and within the county of Middleſex, and elſewhere by the juſtices in ſeſſions. The licences are to be ſtamped with a 5*l.* ſtamp: every one who keeps a number of lunatics, not exceeding ten, ſhall pay the ſum of 10*l.* and above ten the ſum of 15*l.* and 6*s.* 8*d.* on every licence, as a fee to the ſecretary of the commiſſioners. No licence can authoriſe any perſon to keep more than one houſe. The commiſſioners are required annually to viſit licenced houſes, and inſpect their ſtate: on application to the commiſſioners for information concerning any confined perſon, the ſecretary is to ſearch his books, and acquaint the perſons applying with the name of the keepers in whoſe houſe the lunatic is confined. The keeper is required to give notice to the ſecretary, within three days after receiving a patient, who is to file ſuch notice; and every keeper admitting a perſon as lunatic, without an order under the hand of ſome phyſician or ſurgeon, that ſuch perſon is proper to be received, ſhall pay the ſum of 100*l.*

MADNESS, *mania*, in *Medicine*. See MANIA.

MADNESS, *from the bite of enraged animals*, *rabies canina*. The bites of enraged animals, though they were not *mad* at the time they inflicted them, are uſually attended with very grievous conſequences. If the wound is ſlight, the diſcharge of blood from the part is to be encouraged by preſſing it with the fingers, ſucking it in the mouth, or by the application of cupping-glaſſes, or enlarging it with a lancet. It is afterwards to be waſhed with warm ſpirit of wine, and boſſters dipped in the ſame liquor are to be applied to it, repeating the application every three or four hours, till all danger of inflammation is gone off. If the wound be conſiderably deep, it is always neceſſary to enlarge it with the knife, unleſs it have already a very large opening; and, after applying ſpirit of wine for the firſt days, to prevent the bad ſymptoms, it may be eaſily healed with honey or ſome digeſtive ointment, and afterwards with a vulnerary baſſam, as uſed in other wounds. To know whether a dog which has bitten a perſon be or be not *mad*, it is neceſſary to know the marks by which a dog, in that condition, is to be diſtinguiſhed from others. See HYDROPHOBIA.

Perſons bit by a *mad* dog are uſually afflicted with very violent diſorders, ſometimes ſooner, ſometimes later, according to the malignity of the poiſon imbibed by the wound, and other accidents. Many means have been recommended by different perſons, as preſervatives or as remedies in theſe diſorders; the principal of which we ſhall recount in the ſequel of this article.

Dr. de Sauli argues for the *rabies canina*, depending on ſmall worms, of which, he ſays, there is a great number found in the heads of thoſe who die of this diſeaſe. From the analogy of this terrible diſeaſe with others; ſuch as the itch, lues venerea, &c. which, in his opinion, are alſo contagious, by worms communicating from one perſon to another, he was led to think that the cure of the *rabies* was only to be performed by mercury, and the ſucceſs confirmed his theory; for of four men who had all been bit at the ſame time by the ſame wolf, two were treated by the common ſpecifics of plunging in the ſea, &c. and died ſome days after of the *rabies*. The other two, having all the ſigns of an approaching *rabies*, were cured by Dr. de Sauli's method, which is this: if he is conſulted immediately after the perſon is bit, he orders him to be bathed in the ſea, that the common confidence in this method may calm his mind. As ſoon as the patient returns, he puts him on the uſe of Palmarius's powder, compoſed of equal parts of the leaves of rue, vervain, ſage, plantain, polypody, common wormwood, mint, mugwort, baſtard baum, betony, St. John's wort, and leſſer centaury, dried and powdered, with ſome coralline. A dram of this powder is to be taken every morning, in a glaſs of white wine or warm water. This he gives for twenty or thirty days, as there is more or leſs preſumption of the poiſon having entered the blood. From the firſt day of taking the powder, he rubs a dram or two of ung. Neapolit. upon the wound, and ſkin round it, every other day. After doing this thrice, he applies the ointment every third day; and afterwards every fourth day, till he has made uſe of two or three ounces of the ointment. If the patient has delayed ſeveral days to take his advice, he uſes the mercurial friction three or four times a day, for four days, and increaſes the doſe of Palmarius's powder; then forbears the unction two days, leſt a ſalivation ſhould be brought on. Our author likewiſe recommends muſic as of uſe to calm the mind, and divert the fear which people, in danger of this diſeaſe, generally have. Med. Eſſ. Edinb. vol. vi. p. 475. Boerhaave, in order to prevent the effects of a bite inflicted by a *mad* dog, recommends deep ſcarifications in the parts immediately affected and thoſe adjacent to it; the application of large cupping-glaſſes or actual cauteries; and an uninterrupted fomentation, with a brine or pickle made of ſea-ſalt and vinegar; and this treatment is to be continued for ſix months. The patient is alſo to be occaſionally thrown headlong into water, with the moſt terrifying circumſtances; becauſe he apprehends that the advantage of bathing riſes from the terror. He adviſes likewiſe frequent purges with rhubarb, agaric, and the juice of elder-bark; and gentle ſweats every morning by taking a mixture of aromatic vinegar, ſea-ſalt, and warm water. The patient ſhould foment his head, hands, and feet in a bath of water, and drink cold water till he throws it up, by vomit: his diet ſhould be light and laxative. When ſigns of approaching *madneſs* are diſcovered, a large quantity of blood ſhould be taken away, till the patient faints; and the following clyſters mixed with a little vinegar ſhould be injected: viz. ten ounces of barley water, two drams of nitre, and elder vinegar and honey of roſes, of each an ounce: or, ten ounces of rue,

rue, two drams of sea-salt, six drams of vinegar impregnated with marigold-flowers, and an ounce of honey. These should be often repeated, and the patient be often thrown into cold water or washed with it. See HYDROPHOBIA.

Dr. James relates the cure he made of dogs that were *mad*, and how he preserved others from the *rabies*, who had been bit by *mad* dogs, by giving doses of turbith mineral every day, or every other day. The other dogs of the pack that had been bit, died, notwithstanding the famous *powder* medicine, dipping in the sea, and the other common specifics. The Doctor likewise mentions three people who were bit by *mad* dogs, and escaped the *rabies* by the use of the turbith. Phil. Trans. N° 441. § 8.

He directs to rub into the part where the wound was received, a dram or more of mercurial ointment, formed of equal parts of hog's lard and crude quicksilver, as soon as possible after the bite: this should be repeated every day for a week; and in the evening, the patient should take from three to eight grains of turbith mineral, according to his strength and the degree of infection, with an equal quantity of camphor, made into a bolus with any conserve. The dose should be repeated every other evening; but salivation must be avoided. About two or three days after the last dose, the patient should bathe his head in cold water every day, till, as he says, the day before the next full or new moon; and then repeat the dose of turbith mineral three times, as before; and after the third dose, bathe again: and let this method be repeated for the three or four succeeding periods of the moon. He absolutely forbids all nervous and heating medicines. James on Canine Madness.

Mr. Fuller relates the good effects of the PULVIS *antihydrus*, composed of lichen. ciner. terrest. and piper. inge. in preventing the *rabies*. Phil. Tran. N° 448. § 5.

This is much recommended as a preventive medicine by Dr. Mead, who says, that in the space of thirty years, he used it a thousand times and never knew it fail.

A person who had been bit by a *mad* dog, and began to have symptoms of the *rabies*, was saved by having one hundred and twenty ounces of blood taken in a week, and being bathed in cold water. Phil. Trans. ibid. § 6.

Mr. Nourse relates the history of a lad bit in the thumb by a *mad* dog; he took morning and evening a dram of the *pulvis antihydrus* forty days, and bathed in the sea ten days; he was cut for the bone soon after, and recovered very well: nineteen months after which he died, with all the symptoms of the hydrophobia. Phil. Trans. N° 445.

The Tonquinese pretend to an infallible remedy for the bite of the *mad* dog. Their method is to take about fifteen grains of the bell musk; of the purest native cinnabar, and finest vermilion, each about twenty-four grains; and having reduced them separately to impalpable powders, they mix and administer them in about a gill of arrack. This, in two or three hours, generally throws the patient into a found sleep, and perspiration: if not, they repeat the dose, and think the cure certain. See Phil. Trans. N° 474. p. 225. Where Mr. Reid, to whom we are obliged for this receipt, observes, as in the vermilion, that though it be a preparation of cinnabar, yet as the Tonquinese seem to think its virtue different, if it were to be wished, that we knew their method of preparing it, to which they certainly owed

This compolition of musk and cinnabar has been applied with success to other distempers, as an antispasmodic; but as Tonquin vermilion is not easy to be had, Mr. Reid substituted an equal quantity of factitious cinnabar in its stead, and sometimes administered it in rum or brandy instead of arrack. See Musk.

The Tonquinese medicine is sometimes called Cobb's powder, because it was brought over from Tonquin by a Mr. Cobb, formerly in the service of the East India Company.

A good antispasmodic medicine may be prepared by mixing half a dram of Virginian snake-root in powder, with twelve grains of gum asafœtida, and seven grains of gum camphor, into a bolus, with syrup of saffron. Or, one dram of camphor, half an ounce of purified nitre, two drams of powdered Virginian snake-root may be rubbed together in a mortar, and the whole divided into ten doses. Mercury is also a medicine of considerable efficacy, in the prevention and cure of this kind of *madness*. When used as a preventive, it will be sufficient to rub daily a dram of the ointment into the parts about the wound. Vinegar taken freely in the patient's drink and food, is of considerable service. But these or any other medicines must be used for a sufficient length of time.

The following receipt was taken from the church of Caythorp in Lincolnshire, where almost the whole parish were bit by a *mad* dog, and thole was used it recovered, but they who did not, died: take the leaves of rue picked from the stalks and bruised, six ounces; garlick picked from the stalks and bruised, Venice treacle, and mithridate, and the scrapings of pewter, of each four ounces; boil all these over a slow fire in two quarts of strong ale, till one pint be consumed; then keep it in a bottle close stopped, and give nine spoonfuls of it warm to a man or woman, for seven mornings together fasting; and six spoonfuls to a dog. It is confidently said, that this will not fail, if it be used within nine days after the biting of the dog. Some of the ingredients from which the liquor was strained, should be applied to the wounded part. Dr. Parsons advises to rub into the wound, as soon as a person receives the bite, a spoonful or two of common salt, moistened with water, and to repeat it three or four times a day, for a week or ten days; and then to lay on a compress with the same saline preparation. If the wound is very small, it ought to be dilated, that enough of the salt may be the sooner introduced. The inhabitants of Connecticut in New England have long practised this method with success, as an antidote against the bites of *mad* dogs and venomous animals in general.

The most proper thing the surgeon can do on this occasion, is to enlarge the wound with the knife, and promote the flowing out of the blood; then to wash it with salt-water, or with Venice treacle dissolved in vinegar; and when the texture of the part will permit, that is, when only the common integuments, or fleshy parts are wounded, to apply the actual cautery to the wound, and afterwards dress it as other burns. Another method much practised, is to make a tight ligature above the wound, to prevent, as much as may be, the return of the blood by the veins from that part; then to enlarge the wound with a knife, and wash it as before directed; then cauterize it, if the part will admit that operation, if not, cleanse the wound, if deep, by means of a syringe, and apply over it a plaster of the mercurial kind; and if the person be plethoric, to open a vein. After the Venice treacle has been used for a day or two in these cases, the wound is to be dressed with honey, or with the common digestive ointment, mixed with the Ægyptian ointment, or with red precipitate, and be kept open by means of these dressings for some weeks; for wounds of this kind must never be healed too soon, especially when they have not been cauterized. Heister's Surg. p. 99.

The patient should also begin to use either Dr. Mead's PULVIS *antihydrus*, or some of the others already mentioned. He must also rub into the parts about the wound, daily, one dram of the mercurial ointment; which may be continued for ten or twelve days. Afterwards he may take a purge or two; and then begin to use the cold or rather a warm bath; which he may persist in every morning for five or six weeks. In the mean time he may take either one of the bolules of snake-root, asafœtida and camphor, or one of the powders of nitre, camphor, and snake-root, twice a day. He should carefully abstain from flesh, and all salted and high seasoned provisions. He must also avoid strong liquors and turbulent passions, and live modestly on a light and spare diet, and be kept as easy and chearful as possible. Dr. Buchan observes, that he has never seen this course of Medicine, with proper regions, fail in preventing the HYDROPHOBIA. Dom. Med. p. 625. ed. 1770.

Dr. Tissot says, that this *disease* may be cured in the following manner: let the patient lose a considerable quantity of blood; and let bleeding be repeated twice, thrice, or even a fourth time, if circumstances require it: the patient should be put, if possible, into a warm bath, twice a day; and every day twice or three emollient clysters: the wound and adjacent parts should be rubbed with the mercurial ointment twice a day; and the whole limb, in which the wound lies, be rubbed with oil, and wrapped up in an oily flannel. A dose of Cobb's powder should be taken every three hours in a cup of the infusion of lime-tree and elder-flowers: and a bolus, made by mixing one dram of powdered Virginia snake-root, one grain of opium, and of camphor and asafœtida ten grains each, with a sufficient quantity of conserve or rob of elder, should be given every night, and repeated in the morning, if the patient is not easy: washing it down with the above mentioned infusion. When there is a great nausea at the stomach, and a bitterness in the mouth, thirty-five or forty grains of ipecacuanha, in powder, may be taken for a vomit. The patient's food must be light, as panada, soups made of mealy vegetables, &c. and if he should long continue weak and subject to retchings, he may take half a dram of the Peruvian bark thrice a day. Tissot's Advice, &c. p. 263. ed. 1766.

In a case, with respect to which Dr. Fothergill and Dr. Watson held a consultation, they agreed on the following method

method of treatment, though unattended with success. They ordered the patient to be blooded standing, according as his strength would bear; that he should be conveyed to the warm bath, and remain in it as long as it was agreeable: at his return from the bath a clyster of milk and water was injected with a dram of Dover's powder, and half an ounce of mercurial unction was rubbed on his legs and thighs; one scruple of theebaic extract was ordered to be made into twenty pills, three of which were to be taken when he came out of the bath, and two every hour till he seemed disposed to sleep. The Ormskirk remedy, which has been extolled as an infallible preservative in this disorder, had been previously tried without any beneficial effect.

The method of bathing in fresh or salt water, with the terrifying circumstances that attend it, founded indeed on the authority of Celsus, lib. v. cap. 27. and generally recurred to in this disorder, has also been found ineffectual. Mercurials, however commonly recommended, are no sufficient preservatives; nor can we rely on the *pulvis antilyssus* extolled by Mead, nor on the Tonquin medicine. The only method that promised much security, and that is recommended by long and extensive experience is that, advised also by Celsus, of burning the wounded part, and promoting a discharge from the wound as long and as copiously as possible. A sufficient opening for this purpose may be made either by the knife or by actual cautery. In the Highlands it is common, when a person is bit by a mad dog, to cut out the flesh of the wounded part with a razor, to suck the blood in plenty, and to cover the wound with a handful of cobwebs; and in some parts of Europe, they fill the wound with gun-powder as speedily as possible and set fire to it; or if there be no considerable wound, make an incision near it quickly, put gun-powder into it, and then set it on fire; and thus, the explosion both enlarges the wound and prevents its speedy healing. Lond. Med. Obs. vol. v. art. 19, and art. 26.

MADNING-*Money*, old Roman coins, found about Dunstable, are so called by the country people; and have their name from *magnitum*, used by the emperor Antoninus in his itinerary, for Dunstable.

MADON, in *Botany*, a name by which Pliny, and some other authors, have called the white bryony.

MADOR, a word used by some authors to express the sweat which arises under syncope or fainting, whether it be cold or hot, or in larger or smaller quantities.

MADREPORA, in *Natural History*, the name of a genus of fubmarine fubftances, the characters of which are, that they are almoft of a ftony hardneſs, reſembling the coral, and are uſually divided into branches, and pervious by many holes or cavities, which are frequently of a ſtellar figure.

In the Linnæan ſyſtem, this is a genus of LITHOPHYTA: The animal that inhabits it is the molufca: it comprehends thirty-nine ſpecies. According to Donati, the *madrepora* is like the coral in cross hardneſs, which is equal to bone or marble; the colour is white when poliſhed; its ſurface is highly wrinkled, and the wrinkles run lengthwiſe of the branches; in the center there is a ſort of cylinder, which is often pierced through its whole length by two or three holes. From this cylinder are detached about ſeventeen lamina, which run to the circumference in ſtreight lines; and are tranſverſely interſected by other lamina, forming many irregular cavities; the cellules, which are compoſed of theſe lamina ranged into circles, are the habitations of little polypes, which are extremely tender animals, generally tranſparent, and variegated with beautiful colours. M. de Peyſſonel obſerves, that thoſe writers who only conſidered the figures of ſubmarine ſubſtances, denominated that claſs of them, which ſeemed pierced with holes, *pora*; and thoſe, the holes of which were large, they called *madrepora*. He deſires them to be all thoſe marine bodies, which are of a ſtony ſubſtance, without either bark or cruſt, and which have but one apparent opening at each extremity, furniſhed with rays that proceed from the center to the circumference. He obſerves that the body of the animal of the *madrepora*, whoſe fleſh is ſo ſoft, that it divides upon the gentleſt touch, fills the centre; the head is placed in the middle, and ſurrounded by ſeveral feet or claws, which fill the intervals of the partitions obſerved in this ſubſtance, and are at pleaſure brought to its head, and are furniſhed with yellow papillæ. He diſcovered, that its head or centre was lifted up occaſionally above the ſurface, and often contracted and dilated itſelf like the pupil of the eye: he ſaw all its claws moved, as well as its head or centre. When the animals of the *madrepora* are deſtroyed, its extremities become white. In the *madrepora*, he ſays, the animal occupies the extremity; and the ſubſtance is of a ſtony, but more looſe texture than the coral. This is formed, like other ſubſtances of the ſame nature, of a liquor which the animal diſcharges; and he further adds, that there are ſome ſpecies of the polype of the *madrepora*, which are produced ſingly, and others in cluſters. Phil. Tranſ. vol. xlvii. p. 103. 461, &c. See CORAL.

MADRIER, in the *Military Art*, a thick plank, ſometimes armed with iron plates, having a cavity ſufficient to receive the mouth of a petard when charged; with which it is applied againſt a gate, or other body deſigned to be broken down. See PETARD.

MADRIER alſo denotes a long and broad plank, uſed for ſupporting the earth in mining, carrying on ſaps, making caponiers, galleries, and the like.

There are alſo *madriers* lined with tin, and covered with earth, ſerving as defences againſt artificial fires, in lodgments, &c. where there is need of being covered over head.

MADRIGAL, in the modern Italian, Spaniſh, and French poetry, denotes a little amorous piece, containing a certain number of free unequal verſes, not tied either to the ſcrupulous regularity of a ſonnet, or the ſubtlety of an epigram, but conſiſting of ſome tender and delicate, yet ſimple thought, ſuitably expreſſed.

Menage derives the word from *mandra*, which, in Latin and Greek, ſignifies a sheepfold; imagining it to have been originally a kind of paſtoral, or ſhepherd's ſong; whence the Italians formed their *madrigale*, and we *madrigal*. Others rather chooſe to derive the word from *mandegar*; which, in the Spaniſh, ſignifies, to riſe in the morning; the *madrigals* being formerly ſung early in the morning, by thoſe who had a mind to ſerenade their miſtreſſes.

Huet ſuppoſes it to be a corruption of *martegaux*, a name given to the inhabitants of a diſtrict of Provence, who either invented or excelled in this ſpecies of compoſition. If the origin is deduced from the Spaniards, it may have taken its name from a town in Spain, called *Madrigal*.

The *madrigal*, according to M. le Brun, is an epigram without any thing very brisk and ſprightly in its fall, or cloſe: ſomething very tender and gallant is uſually the ſubject of it: and a certain beautiful, noble, yet chaſte ſimplicity forms its character.

The *madrigal* is uſually looked on as the ſhorteſt of all the leſſer kinds of poems, except the epigram: it may conſiſt of fewer verſes than either the ſonnet, or roundelay. There is no other rule regarded in mingling the rhymes and verſes of different kinds, but the fancy and convenience of the author. This poem, however, really allows of leſs licence than many others; whether we regard the rhyme, the meaſures, or the purity of expreſſion.

The term is alſo applied to a muſical compoſition of three or more parts for different voices, adapted to the words of ſuch poems.

MAEL, *Corean*, in the *Language of the Ceylonſe*, the flowering cinnamon-tree. This is a name given to a peculiar ſpecies of the cinnamon-tree, which is all the year round found full of flowers. The flowers are not eaſily to be diſtinguiſhed from the very ſmall cinnamon-flowers, but they produce no fruit, which the flowers of the fine cinnamon always do. The bark is much like that of the beſt cinnamon, in external appearance; but it has very little taſte or ſmell. The tree grows very large, and the inhabitants ſometimes tap it, by boring a hole into the trunk, at which it bleeds a thin watery juice, in the manner of our birch-tree.

MÆMACTERION, *Μαιμακτηριων*, in *Chronology*, the fourth month of the Athenian year. It contained twenty-nine days, and anſwered to the latter part of our September and beginning of October. The Boeotians called it *alcomenius*.

It took its name from the feſtival *Memacteria*, ſacred to Jupiter, kept at this time.

MÆMACYLON, in the *Materia Medica*, a name given by Dioſcorides, and the ancients in general, to the fruit of the *arbutus*, or ſtrawberry-tree.

MÆNA, in *Zoology*, the name of a ſmall fiſh, caught in vaſt abundance about the ſhores of the Mediterranean, and common in the markets of Italy, where they are accounted but a poor ſort of fiſh, and ſold at a very cheap rate. It is ſomewhat of the figure of the pearch, but broader and thinner, and is ſeldom above four or five inches in length.

MÆNA *cornuta*, in *Ichthyology*, a name given by many authors to the ſmaris. It is not very improper, for they are both of the ſame genus of the SPARUS, and are very nearly allied to one another; the principal difference conſiſting in the tail and belly fins of the ſmaris being red.

MAESTOSO, or MAESTOSOO, in the *Italian Muſic*, ſignifies to play with grandeur, and conſequently ſlow, but yet with ſtrength and fortitude.

MAJOR-

MAFORTIUM, among the *Romans*, a veil, or head-dress, worn by the married women.

MAGADA, in *Mythology*, a title under which Venus was known and worshipped in Lower Saxony; where this goddess had a famous temple, which was treated with respect even by the Huns and Vandals, when they ravaged the country. It is said to have been destroyed by Charlemagne.

MAGAS, Μαγαδις, from μαγαδιζω, *to sing or play in unison* or *octave*, the name of a musical instrument, in use among the ancients.

There were two kinds of *magades*, the one a string instrument, formed of twenty chords, arranged in pairs, and tuned to unison or octave, so that they yielded ten sounds; the invention whereof is ascribed, by some to Sappho; by others, to the Lydians; and, by some, to Timotheus of Miletus.

The other was a kind of flute, which, at the same time, yielded very high and very low notes. The former kind was, at least, much improved by Timotheus of Miletus, who is said to have been impeached of a crime; because by increasing the number of chords, he spoiled and discredited the ancient music.

MAGAS, in the *Ancient Music*, is also used to denote the bridge of any instrument.

MAGAURI, in *Ornithology*, the name of a Brasilian bird, a species of STORK: it is of the size of the common white stork; its neck is a foot long, and its beak strait and pointed, and nine fingers breadth in length; its legs long and naked; its tail is short; its head, neck and body, are covered with snow-white feathers; on the throat these are very long, very white and valuable; its wings and tail have their long feathers black; its legs are red; and its flesh eatable.

MAGAZINE, in the *Military Art*, a place in fortified towns, where all sorts of stores are kept; and where carpenters, wheelwrights, smiths, &c. are employed in making things needful to furnish out the train of artillery.

MAGAZINE, *powder*, is a building constructed for keeping large quantities of powder. These *magazines* were formerly towers erected in the town walls; but many inconveniences attending this situation of them they are now placed in different parts of the town. They were at first constructed with Gothic arches; but M. Vauban, finding these too weak, constructed them in a semicircular form of the following dimensions, viz. fifty feet long within, and twenty-five broad; the foundations eight or nine feet thick; and eight feet high from the foundation to the spring of the arch; the floor about two feet from the ground to prevent damp; and consequently six feet for the height of the story.

The thinnest part or haunches of the arch is three feet thick, and the arch made of four lesser ones, one over the other, and the outside of the whole terminated in a slope to form the roof; from the highest part of the arch to the ridges is eight feet, which makes the angle somewhat greater than ninety degrees; the two wings, or gable ends, are four feet thick, raised somewhat higher than the roof, as is customary in other buildings; as to their foundations they are five feet thick, and as deep as the nature of the ground required.

The piers or long sides are supported by four counterforts, each of six feet broad, and four feet long, and their interval twelve feet; between the intervals of the counterforts, are air-holes, in order to keep the *magazine* dry and free from dampness; the dices of these air-holes are commonly a foot and a half every way, and the vacant space round them three inches, made so, as the in and outside be in the same direction. The dices serve to prevent an enemy from throwing fire in, to burn the *magazine*, and for a farther precaution, it is necessary to stop these holes with several iron plates, that have small holes in them like a skimmer, otherwise fire might be fled to the tail of some small animal, and so drive it in that way; this would be no hard matter to do, since where this precaution has been neglected, egg-shells have been found within, that have been carried there by weasles.

To keep the floor from dampness, beams are laid long ways, and to prevent these beams from being soon rotten, large stones are laid under them; these beams are eight or nine inches square, or rather ten high and eight broad, which is better, and eighteen inches distant from each other; their interval is filled with dry sea coals, or chips of dry stones, then over these beams are others laid cross-ways, of four inches broad, and five high, which are covered with two inch planks.

Mr. Belidor would have brick walls made under the floor, instead of beams, and a double floor laid on the cross-beams; which does not appear to be so well as the manner proposed here; the reader is, however, at liberty to choose the method he likes best.

To give light to the *magazine*, a window is made in each wing, which are shut up by two shutters of two or three inches thick, one within and the other without; that which is on the outside is covered with an iron plate, and is fastened with bolts, as well as that on the inside. These windows are made very high, for fear of accidents, and are opened by means of a ladder, to give air to the *magazine* in fine dry weather.

There is likewise a double door made of strong planks, the one opens on the outside, and the other within; the outside one is also covered with an iron plate, and both are locked by a strong double lock; the store-keeper has the key of the outside, and the governor that of the inside: the door ought to face the south nearly, if possible; in order to render the *magazine* as light as can be, and that the wind blowing in may be dry and warm. Sometimes a wall of ten feet high is built round the *magazine* about twelve distant from it, to prevent any thing from approaching it without being seen. Mr. Muller has proposed some alterations, by way of improvement, in M. Vauban's construction, for which see his Practical Fortification, p. 219, *&c.*

If large *magazines* are required, the piers or side walls which support the arch, should be ten feet thick, seventy-two feet long, and twenty-five feet high; the middle wall, which supports the two small arches of the ground floor, eight feet high and eighteen inches thick, and likewise the arches: the thickness of the great arch should be three feet six inches, and the counterforts, as well as the air-holes, the same as before. *Magazines* of this kind should not be erected in fortified towns, but in some inland part of the country near the capital, where no enemy is expected. It has been observed, that after the centres of semicircular arches are struck, they settle at the crown and rise up at the haunches; now as this shrinking of the arches must be attended with ill consequences, by breaking the texture of the cement after it has been partly dried, and also by opening the joints of the voussoirs at one end, Mr. Hutton, in his Treatise on Bridges, has proposed to remedy this inconvenience, with regard to bridges, by the arch of equilibration: and as the ill effect is much greater in powder *magazines*, he has also proposed to find an arch of equilibration for them also; and to construct it when the span is twenty feet, the pitch or height ten, which are the same dimensions as those of the semicircle, the inclined exterior walls, at top, forming an angle of 113°, and the height of their angular point above the top of the arch equal to seven feet: this curious question was answered in 1775, by the Rev. Mr. Wildbore, and the solution of it may be found in Mr. Hutton's Miscellanea Mathematica.

MAGAZINE, *artillery*, or the *magazine* to a field battery, is usually made about fifty or sixty yards behind the platform. This is a cavity dug in the ground about four feet deep, and the earth thrown between the pit and the platform; the sides of the pit are sometimes planked round to keep it dry and to prevent the earth from crumbling in: and the powder-barrels placed here are covered with hurdles and earth, or tanned hides, to preserve the powder from wet or fire. The communication to the *magazine* is by a sloping trench beginning to descend about five or six yards behind the platform; and the earth is thrown on that side where it will most conveniently cover the persons who remove the barrels of powder from the great *magazine* to the *battery* or small *magazine*. When there are many cannons in the battery, and the service is quick, it is customary to have, for every two pieces, a small *magazine* to hold twenty or thirty barrels of powder; this is placed about fifteen or twenty yards behind the platform, and against the merlon between the cannon; and as these barrels are used, they are replaced by others from the great *magazine*. At each *magazine* a centinel is placed to prevent accidents; and in order to prevent persons from coming into the battery and *magazines* who have no business there, a trench is sometimes dug behind the *magazine* and carried into the trenches which communicate between the *magazine* and battery.

MAGAZINE, or POWDER-ROOM, in a ship, a close room or store-house built in the fore, or afterpart of a ship's hold, to contain the gunpowder used in battle, &c. This apartment is strongly secured against fire, and no person is suffered to enter it with a lamp or candle; it is therefore lighted, as occasion requires, by means of the candles or lamps which are fixed in the LIGHT-room contiguous to it.

MAGBOTE, or MEGBOTE, formed of the Saxon *mag*, i. e. *vegnator*, and *bote*, *compositio*, in our *Old Writers*, a compensation for the slaying or murder of one's kinsman, in ancient times, when corporal punishments for murder, &c. were sometimes commuted into pecuniary fines, if the friends and relations of the party were so satisfied.

MAGDALEN, *Religious of St.* MAGDALEN, is a denomination given to divers communities of nuns, consisting, generally, of penitent courtezans; sometimes also called *Magdalanettes*.

Such are those at Metz, established in 1452; those at Paris, in 1492; those at Naples first established in 1324, and endowed by queen Sancha, to serve as a retreat for public courtezans, who should betake themselves to repentance; and those of Rouen and Bourdeaux, which had their original among those of Paris in 1618.

In each of these monasteries there are three kinds of persons and congregations; the first consist of those who are admitted to make vows, and these bear the name of *St. Magdalen*; the congregation of St Martha is the second, and is composed of those whom it is not judged proper to admit to vows; finally, the congregation of St. Lazarus is composed of such as are detained there by force.

The religious of *St. Magdalen* at Rome were established by pope Leo X. Clement VIII. settled a revenue on them, and further appointed, that the effects of all public prostitutes, dying intestate, should fall to them; and that the testaments of the rest should be invalid, unless they bequeathed a portion of their effects, which was to be at least a fifth part, to them.

MAGDALEN *hospital*. See HOSPITAL.

MAGDALEO, a word used by dispensatory writers, to express any thing made up into a cylindric form. The common rolls of plasters which the apothecaries make up, to be ready for spreading upon occasion, are thus called, as also the rolls of sulphur or common brimstone.

MAGDALEON, or MAGDALIDES, the same as Magdaleons, rolls of sulphur, plaister, &c.

MAGELLANIC *clouds*, whitish appearances like clouds, seen in the heavens towards the south pole, and having the same apparent motion as the stars.

They are three in number, two of them near each other. The largest lies far from the south pole; but the other two are not many degrees more remote from it than the nearest conspicuous star, that is, about eleven degrees. Mr. Boyle conjectures, that if these clouds were seen through a good telescope, they would appear to be multitudes of small stars, like the milky way. Boyle's Works abr. vol i. p. 295.

MAGELLANIC *goose, anser magellanicus*, in *Ornithology*. See GOOSE.

MAGGOT, the common name of the fly-worm, bred in flesh, from the egg of the great blue flesh-fly. Notwithstanding the distaste for this animal, its figure and structure of parts are greatly worth attending to, and may serve as a general history of the class of worms produced from the eggs of flies.

This animal is white and fleshy; its body is composed of a number of rings, like the bodies of caterpillars, and other the like insects, and is capable at the pleasure of the animal, of assuming different figures, being, at times, more or less extended in length, and consequently more or less thick.

Notwithstanding that this creature has no legs, it is able to move itself very swiftly, and, in its first attempt to move its body, is extended to its greatest length, and assumes something of the figure of a pointed cone. The pointed part of this cone is the head of the animal, and is not separated from the next ring by any deeper furrow than the rest of the rings are from one another. In some states of the animal one may see two short horns thrust out from the head; but what are more constantly observable are two brown fealy hooks; these are, however, sometimes hid, and have each of them a sheath, or case, into which the animal can retract them at pleasure. These hooks are bent into an arch, the concavity of which is toward the plane on which the creature is placed, and they are thickest at their insertion in the head, and thence diminish gradually, till they terminate in a fine sharp point.

These two hooks are placed in a parallel direction, and can never come together, and therefore cannot serve in the place of teeth to grind the food between, but merely to pull and sever it to pieces, that it may be of a proper size for the mouth of the creature.

The creature has besides these two hooks a kind of dart, which is of about a third part of their length, and is placed at an equal distance between them. This also is brown like them, and scaly; it is quite strait, and terminates in a fine point. The hooks have, as it were, two scaly thorns at their points, and this dart seems intended, by reiterated strokes, to divide and break the pieces of flesh these have separated from the rest, into smaller parts.

Immediately below the aperture for the egress of the hooks, is placed the mouth of the animal; the creature does not shew this little opening unless pressed; but if the pressure be properly managed, it will sufficiently open it, and there may be discovered within it a small protuberance, which may very naturally be supposed either the tongue, or the sucker of the animal.

The hooks in this creature not only supply the place of teeth, but also of legs; since it is by fastening these hooks into the substance it is placed on, and then drawing up its body to it, that it pulls itself along.

The back of the creature lowers itself by degrees as it approaches the extremity of the belly, and near the place where the back begins to lower itself, are placed the creature's two principal organs of respiration. One may perceive there two small roundish brown spots; these are very easily distinguishable by the naked eye, because the rest of the body of the creature is white; but if we take in the assistance of glasses, each of these spots appears to be a brown circular eminence raised a little above the rest of the body. On each of these spots one may also discover three oblong oval cavities, something in the shape of button-holes; these are situated in a parallel direction to one another, and their length nearly in a perpendicular direction to that of the body of the animal.

These apertures are so many stigmata or air-holes, openings destined to admit the air necessary to the life of the animal. The creature has six of these stigmata, three in each side of its body.

The great transparence of the body of this insect, gives us an opportunity also to distinguish that it has on each side a large white vessel running the whole length of the body. It is easy to follow the course of these vessels through their whole length, but they are most distinct of all toward its hinder part, and they are always seen to terminate each in the brown spot before described; this leaves us no room to doubt but that they are the two principal tracheæ.

These posterior tracheæ have been well known to the later naturalists; but there are two others besides these which they seem not to have distinguished. These are situated in the anterior part of the animal, and are easily discovered by following the course of the tracheæ on each side; for though these all the way diminish in their diameters as they approach the head of the animal, yet it may be easily enough seen where they terminate, which is (taking the head for one ring) in the junction of the second and third ring. In this place the naked eye easily discovers a small spot at the extremity of each, which viewed with a good microscope appears to be a plain stigma, of the figure of a funnel with half of it cut off, and very elegantly indented, and as it were fringed at the edges.

These stigmata in the anterior part of the body, are as constant in this creature, as the posterior ones, but it seems to have none of those which the caterpillar class are furnished with along their sides; though it seems from the structure of the fly it afterwards transforms itself into, that it ought to have them, since that has stigmata in their places.

The ramifications of the two great tracheæ are very beautifully seen in this creature, especially on its belly; and it is remarkable that no vessel analogous to the great artery in the caterpillar class can be discovered in these; though, if there were any such, their great transparence must needs make them very easily distinguishable; nor could its dilarations and contractions, if so considerable as in that class of animals, be less so. See CATERPILLAR.

Malpighi imagined that artery, in the caterpillar-class, a series of hearts; in its place, however, there may be seen in these animals a true heart. It is easy to observe in these creatures, about the fourth ring of the body, a small fleshy part, which has alternate contractions and dilatations, and is not only discoverable in the body by means of the creature's transparence, but on making a proper section of them in the second, third, and fourth rings, will be thrown out of the body of the creature, and will afterwards continue its beats for some minutes. Reaumer's Hist. Insect. vol iv. p. 165, &c.

MAGI, or MAGIANS, a title which the ancient Persians gave to their wise men, or philosophers.

The learned are in great perplexity about the original of the word *magus, magi*. Plato, Xenophon, Herodotus, Strabo, &c. derive it from the Persian language, in which it signified a *priest*, or person appointed to officiate in holy things; as *Druid*, among the Gauls; *Gymnosophist*, among the Indians; and *Levite*, among the Hebrews. Others derive it from the Greek μεγας, *great*; which they say, being borrowed of the Greeks, by the Persians, was returned in the form of μαγος; but Vossius, with more probability, brings it from the Hebrew הגה *hagu, to meditate*; whence מהגים, *magim*, in Latin *meditabundi*, q. d. people addicted to meditation. See the sequel of this article.

Magi, among the Persians, answers to σοφοι, or σοφισται, among the Greeks; *sapientes*, among the Latins; *Druids*, among the Gauls; *Gymnosophists*, among the Indians; and *prophets*, or *priests*, among the Egyptians.

The ancient *Magi*, according to Aristotle and Laertius,

were the ſole authors and conſervators of the Perſian philoſophy; and the philoſophy principally cultivated among them, was theology, and politics; they being always eſteemed as the interpreters of all law, both divine and human; on which account they were wonderfully revered by the people. Hence, Cicero obſerves, that none were admitted to the crown of Perſia, but ſuch as were well inſtructed in the diſcipline of the *magi*; who taught *ta diaitêsai*, and ſhewed princes how to govern.

Plato, Apuleius, Laertius, and others, agree, that the philoſophy of the *magi* related principally to the worſhip of the gods: they were the perſons who were to offer prayers, ſupplications, and ſacrifices, as if the gods would be heard by them alone.

But, according to Lucian, Suidas, &c. this theology, or worſhip of the gods, as it is called, about which the *Magi* were employed, was little more than the diabolical art of divination; ſo that *mageia*, ſtrictly taken, was the art of divination. Theſe people were held in ſuch veneration among the Perſians, that Darius, the ſon of Hyſtaſpes, among other things, had it engraven on his monument, that he was the maſter of the *Magi*.

Philo Judæus deſcribes the *Magi* to be diligent inquirers into nature, out of the love they bear to truth; and who, ſetting themſelves apart from other things, contemplate the divine virtues the more clearly, and initiate others in the ſame myſteries.

The *Magi*, or *Magians*, formed one of the two grand ſects into which the idolatry of the world was divided between five and ſix hundred years before Chriſt. Theſe abominated all thoſe images which were worſhipped by the other ſect, denominated Sabians, and paid their worſhip to the Deity under the emblem of fire. Their chief doctrine was, that there were two principles, one of which was the cauſe of all good, and the other the cauſe of all evil. The former was repreſented by light, and the latter by darkneſs, as their trueſt ſymbols; and of the compoſition of theſe two they ſuppoſed that all things in the world were made. The good god they called Yazdan, denominated by the Greeks Oroſmades: and the evil god Abraman, whom the Greeks called Arimanius. Concerning theſe two Gods, there was this difference of opinion among them; that whereas ſome held both of them to have been from all eternity, there were others who contended, that the good God only was eternal, and that the other was created. But they both agreed in this, that there will be a continual oppoſition between theſe two, till the end of the world; when the former ſhall overcome the latter; and that from thenceforth each of them ſhall have his world to himſelf; that is, the good God ſhall have his world, with all good men with him, and the evil god his world with all evil men with him. The good God they always worſhipped before fire, as being the cauſe of light, and eſpecially before the ſun, as being, in their opinion, the moſt perfect fire, and cauſing the moſt perfect light: and, for this reaſon they had, in all their temples, fire continually burning on altars, erected in them for that purpoſe. Before theſe ſacred fires they performed all their publications of devotion, as they likewiſe practiſed their private devotions before their private fires in their own houſes. Such were the tenets of this ſect, when Smerdis, who was the principal leader of it, having uſurped the crown after the death of Cambyſes, was ſlain by ſeven princes of Perſia; and many of the *Magians* who adhered to him ſhared likewiſe the ſame fate. In conſequence of this event thoſe who adopted the ſentiments of this ſect were called, by way of derſion, *Magians*, from *mist-guſt*, which ſignifies, in the language of the country then in uſe, *one that has his ears cropped*. The whole ſect of the *Magians* would ſoon have ſunk into utter extinction, if it had not in a few years after this period, been revived and reformed by Zoroaſter. This celebrated philoſopher, called by the Perſians Zerduſht or Zaratuſh, began about the thirty-ſixth year of the reign of Darius, to reſtore and reform the *Magian* ſyſtem of religion. He was not only excellently ſkilled in all the learning of the Eaſt, that prevailed in his time; but likewiſe thoroughly verſed in the Jewiſh religion, and in all the ſacred writings of the Old Teſtament that were then extant, whence ſome have inferred that he was a native Jew both by birth and profeſſion; and that he had been ſervant to one of the prophets, probably to Ezekiel or Daniel. He made his firſt appearance in Media, in the city of Xiz, now called Aderbijan, as ſome ſay; or according to others, in Echatana, now called Tauris. Inſtead of admitting the exiſtence of two firſt cauſes, with the *Magians*, he introduced a principle ſuperior to them both, one ſupreme God, who created both theſe, and out of theſe two produced, according to his ſovereign pleaſure, every thing elſe. See Iſaiah v. 5, 6, 7.

In order to avoid making God the author of all evil, he taught, that God originally created only light or good, and that darkneſs or evil followed it by conſequence, as the ſhadow doth the perſon. According to his doctrine there was one ſupreme Being independently, and ſelf-exiſting from all eternity: under him there were two angels, one the angel of light, the author and director of all good; and the other the angel of darkneſs, who is the author and director of all evil: theſe two, out of the mixture of light and darkneſs made all things that are; and they are in a ſtate of perpetual conflict; ſo that where the angel of light prevails, there the moſt is good, and where the angel of darkneſs prevails, there the moſt is evil: this ſtruggle ſhall continue to the end of the world; and then there ſhall be a general reſurrection, and a day of judgment; after which the angel of darkneſs and his diſciples ſhall go into a world of their own, where they ſhall ſuffer in everlaſting darkneſs the puniſhment of their evil deeds; and the angel of light and his diſciples ſhall go into a world of their own, where they ſhall receive, in everlaſting light, the reward due unto their good deeds: and henceforward they ſhall for ever remain ſeparate. Thoſe who remain of this ſect in Perſia and India, in the preſent day, retain the ſame doctrines. Zoroaſter alſo cauſed fire-temples to be erected wherever he came: for having feigned, that he was taken up into heaven, and there inſtructed in the doctrines he taught by God himſelf, out of the midſt of a great and moſt bright flame of fire, he taught his followers, that fire was the trueſt ſhechinah of the divine preſence; that the ſun being the moſt perfect fire, God had there the throne of his glory, and the reſidence of his divine preſence in a peculiar manner; and next to this in our elementary fire: and, therefore, he ordered them to direct all their worſhip to God, firſt towards the ſun, which they called Mithra, and next towards their ſacred fires: and when they came before theſe fires to worſhip, they always approached them on the weſt ſide, that having their faces towards them, and alſo towards the riſing ſun at the ſame time, they might direct their worſhip towards both. And in this poſture they always performed every act of their worſhip. Zoroaſter alſo pretended, that he brought ſome of the heavenly fire with him on his return, and placed it on the altar of the firſt fire-temple, which he erected at Xiz, in Media, whence it was propagated to all the reſt. And on this account, their prieſts carefully watch it, and never ſuffer it to be extinguiſhed.

Zoroaſter, having aſſumed the character of a divine prophet and reformer of religion, retired into a cave, devoting himſelf to prayer and meditation, where he compoſed the book called the Zend, in which his pretended revelations were contained. From Media he removed into Bactria; and he went alſo into India among the Brachmans, and having acquired all their knowledge in mathematics, philoſophy, and aſtronomy, returned and communicated the knowledge he had acquired to his *Magians*: and thus they became famous for their ſkill in theſe ſciences; ſo that a learned man and a *Magian* were equivalent terms. The vulgar conceived of them as perſons actuated and inſpired by ſupernatural powers; and hence thoſe who pretended to wicked and diabolical acts aſſumed the name of *Magians*; and the term magician acquired its evil meaning. However this diſtinguiſhed knowledge was confined to thoſe who were by way of eminence, the *Magi*, or the prieſts; who, like thoſe of the Jews, being of the ſame tribe, appropriated their learning to their own families. Theſe prieſts were diſtributed into three orders, viz. the inferior clergy, the ſuperintendants who governed them, and the archimagus, or high-prieſt: and their churches or temples were alſo of three ſorts, parochial or oratories; fire-temples, in which fire was kept continually burning on a ſacred altar; and the fire-temple in which the archimagus reſided. Zoroaſter at length carried his religious ſyſtem to the royal court of Suſa, and made Darius a proſelyte, together with moſt of the great men of the kingdom. Darius was ſo attached to the *Magian* ſyſtem, that he became an archimagus, and ordered, that among other titles, it ſhould be engraven on his monument, that he was *maſter of the Magians*. Hence the kings of Perſia were conſidered as pertaining to the ſacerdotal tribe, and were always initiated in the ſacred order of the *Magians*, before they took on them the crown, or were inaugurated into the kingdom.

Zoroaſter, after this ſucceſs, returned to Balch, in Bactria, where, according to his own inſtitution, he was obliged to reſide, as archimagus or head of the ſect, and there he reigned in ſpirituals, with the ſame authority, over the whole empire, as the king did in temporals: and from hence probably aroſe the miſtake of making him king of Bactria. Zoroaſter, at length, fell a ſacrifice to his zeal; for having concerted an enterprize againſt Argaſp, king of

of the oriental Scythians, who was a zealous Sabian, to draw him over to his religion; the Scythian prince invaded Bactria with an army, and slew Zoroaster, with all the priests of this patriarchal church, to the number of eighty persons, and demolished all the fire-temples in that province. This is said to have happened in the 258th year of Darius. Pythagoras derived a great part of his knowledge from Zoroaster, and his disciples the *Magians*. Prideaux's Conn. vol. i.

Their descendents, the modern *Magi*, or fire-worshippers, are divided into three classes; whereof the first, and most learned, neither eat nor kill animals; but adhere to the old institution of abstaining from living creatures. The *Magi* of the second class refrain only from tame animals; nor do the last kill all indifferently, it being the first and distinguishing settled notion of them all, *viz. μετεμψυχωσις εστιν, that there is a transmigration of souls.* See METEMPSYCHOSIS and GABRES.

MAGIC, MAGIA, Μαγεια, in its ancient sense, the science, or discipline and doctrine, of the *Magi*, or wise-men of Persia. See the preceding article.

MAGIC, in a more modern sense, is a science which teaches to perform wonderful and surprising effects.

The word *magic* originally carried with it a very innocent, nay, a very laudable, meaning; being used purely to signify the study of wisdom, and the more sublime parts of knowledge; but, in regard the ancient *Magi* engaged themselves in astrology, divination, sorcery, &c. the term *Magic*, in time, became odious, and was only used to signify an unlawful and diabolical kind of science, depending, as it was pretended, on the assistance of the devil, and departed souls.

If any wonder how so vain and deceitful a science should gain so much credit and authority over men's minds, Pliny gives the reason of it. It is, says he, because it has possessed itself of three sciences of the most esteem among men, taking from each all that is great and marvellous in it. Nobody doubts but it had its origin in medicine, and that it insinuated itself into the minds of people, under pretence of affording extraordinary remedies. To these fine promises is added every thing in religion that is pompous and splendid, and that appears calculated to blind and captivate mankind. And, lastly, it mingled judiciary astrology with the rest, persuading people, curious of futurity, that it saw every thing to come in the heavens. Agrippa divides *magic* into three kinds, *natural, celestial,* and *ceremonial*, or *superstitious*.

MAGIC *natural* is no more than the application of natural active causes to passive things or subjects; by means whereof many surprising, but yet natural effects are produced.

MAGIC *celestial* borders nearly on judiciary astrology; it attributes to spirits a kind of rule, or dominion, over the planets; and to the planets a dominion over men; and on these principles, builds a ridiculous kind of system.

MAGIC *superstitious*, or *goetic*, consists in the invocation of devils: its effects are usually evil and wicked, though very strange, and seemingly surpassing the powers of nature; they are supposed to be produced by virtue of some compact, either tacit or express, with evil spirits; but the truth is, these supposed compacts have not the power that is usually imagined; nor do they produce half those effects ordinarily ascribed to them.

MAGIC *lantern*, an optic machine contrived by Kircher: (See his Ars Magna Lucis et Umbræ, p. 768, 769), by means whereof little painted images are represented on an opposite wall of a dark room, magnified to any bigness at pleasure.

MAGIC *lantern, construction of the.* Suppose A B C D (*Tab. Optics, fig.* 10.) a common tin lantern, to which is added a tube to draw out F G. In H is fixed a metallic concave speculum, of a foot diameter at most, or four inches at least; or, in lieu thereof, near the extremity of the tube, there must be placed a convex lens, consisting of a segment of a small sphere, its diameter not exceeding a few inches. The use of this lens is to throw a strong light upon the image; and sometimes a concave speculum is used with the lens, in order to make the image still more vivid. In the focus of the concave speculum, or lens, is placed a lamp L; within the tube, where it is soldered to the side of the lantern, is placed a small lens, convex on both sides, being a portion of a small sphere, having its focus about the distance of three inches. The extreme part of the tube F M, is square, and has an aperture quite through, so as to receive an oblong frame N O, passed into it; in this frame are round holes, an inch or two in diameter. According to the bigness of these holes are drawn circles on a plain thin glass; and in these circles are painted any figures or images, at pleasure, with transparent water-colours. These images fitted into the frame, and placed inverted, at a little distance from the focus of the lens I, will be projected on an opposite white wall of a dark room, prodigiously magnified in all their colours, and in erect situation. By having the instrument so contrived, as that the lens I may move in a slide, the focus may be made and consequently the image appear distinct, at almost any distances.

Or thus:—Every thing being managed as in the former, into the sliding tube F G, insert another convex lens K, the segment of a sphere somewhat larger than I. Now, if the picture be brought nearer to I than the distance of the focus, diverging rays will be propagated, as if they proceeded from the object; wherefore, if the lens K be so placed, as that the object is very near its focus, the image will be exhibited on the wall, exceedingly magnified.

MAGIC *lantern, theory of the.* The lamp being placed in the focus of the concave speculum, or any convex glass, the rays will be propagated parallel to each other, and the image will be strongly illumined, and will therefore emit a great number of rays upon the lens I. But, being supposed to be placed near the lens I, the inverted image of the picture inverted must be formed on the opposite wall, exceedingly magnified, after its refraction through the lens; and it will be still the more magnified, as the lens is a segment of a less sphere, and as the picture is placed nearer the focus of the lens: in a dark place, therefore, the picture will be represented prodigiously large and extremely vivid.

To heighten the light, specula are preferred to lenses; the focus of a speculum being nearer than that of a lens. De Chales orders the diameter of the lens I to be two, four, or five digits, and in a subduple proportion to the other K; *i. e.* if I be five digits, K must be ten; and the diameter of the speculum, according to the same, is to be two digits. Zahnius chooses to have the diameter of I $\frac{1}{10}$ of a foot; and that of K one foot and $\frac{1}{2}$, &c.

Little animals being included in the *magic lantern*, in the manner observed in speaking of the microscope, or any little transparent objects fastened to a slice of talc or glass, and substituted instead of images, the *magic lantern* will become a microscope.

A view of the instrument itself may be seen in *fig.* 10, N° 2, in which *b h e* is the lens that throws the light of the candle or lamp *a* on the object *d e*, and *k l* is the lens that magnifies the image *f g* on the white wall F H in a dark room. It is plain, that if the tube *k u l m* be contracted, and the glass *d e* be brought nearer the object *d e*, the image *f g* will be enlarged; and hence this *lantern* has been called the *lanterna magiographica*. On the contrary, if the tube be protracted, the image of the object will be diminished.

M. Euler proposed a scheme to introduce vision by reflected light into the *magic lantern*, as well as the *solar* MICROSCOPE, by which many inconveniences to which those instruments are subject, might be avoided. For this purpose, he says, that nothing is necessary but a large concave mirror, perforated as for a telescope, and that the light be so situated, that none of it may pass directly through the perforation, so as to fall on the images of the objects upon the screen. He proposes to have four different machines for objects of different sizes; the first for those of six feet long, the second for those of one foot, the third for those of two inches, and the fourth for those of two lines. An idea of this contrivance is given in *Tab. III. Optics fig.* 42, in which O D represents the concave mirror, E the object, *l, l*, the lights, and A the lens, through which the rays are transmitted to the screen. Nov. Com. Petrop. vol iii. p. 303.

MAGIC *square*, a square figure, formed of a series of numbers, in mathematical proportion; so disposed in parallel and equal ranks, as that the sums of each row, taken either perpendicularly, horizontally, or diagonally, are equal.

The several numbers which compose any square number (for instance, 1, 2, 3, 4, 5, &c. to 25 inclusive, which compose the square number 25) being disposed after each other, in a square figure of 25 cells, each in its cell; if then you change the order of these numbers, and dispose them in the cells in such manner, as that the five numbers which fill an horizontal rank of cells, being added together, shall make the same sum with the five numbers in any other rank of cells, whether horizontal, or vertical, and even the same number with the five in each of the two diagonal ranks; this disposition of numbers is called a *magic square*; in opposition to the former disposition, which is called a *natural square*. See the figures following:

One

One would imagine, that these *magic squares* had that name given them, in regard this property of all their ranks, which, taken any way, make always the same sum, appeared extremely surprising, especially in certain ignorant ages, when mathematics passed for *magic*; but there is a great deal of reason to suspect, that these squares merited their name still farther, by the superstitious operations they were employed in, as the construction of talismans, &c. for, according to the childish philosophy of those days, which attributed virtues to numbers, what virtues might not be expected from numbers so wonderful?

However, what was at first the vain practice of makers of talismans and conjurers, has since become the subject of a serious research among mathematicians; not that they imagine it will lead them to any thing of solid use or advantage. *Magic squares* favour too much of their original to be of much use; but only as it is a kind of play, where the difficulty makes the merit, and it may chance to produce some new views of numbers, which mathematicians will not lose the occasion of.

Eman. Moschopulus, a Greek author of no great antiquity, is the first that appears to have spoken of *magic squares*: and, by the age wherein he lived, there is reason to imagine he did not look on them merely as a mathematician. However, he has left us some rules for their construction. In the treatise of Cor. Agrippa, to much accused of *magic*, we find the squares of seven, numbers, viz. from three to nine inclusive, disposed *magically*; and it must not be supposed, that those seven numbers were preferred to all the other without some very good reason: in effect, it is because their squares, according to the system of Agrippa, and his followers, are planetary. The square of 3, for instance, belongs to Saturn; that of 4 to Jupiter; that of 5 to Mars; that of 6, to the sun; that of 7 to Venus; that of 8, to Mercury; and that of 9, to the moon. M. Bachet applied himself to the study of *magic squares*, on the hint he had taken from the planetary squares of Agrippa, as being unacquainted with the work of Moschopulus, which is only in manuscript in the French king's library; and, without the assistance of any author, he found out a new method for those squares whose root is uneven; for instance, 25, 49, &c. but he could not make any thing of those whose root is even.

After him came M. Frenicle, who took the same subject in hand. A certain great algebraist was of opinion, that whereas the sixteen numbers which compose the square, might be disposed 20922789888000 different ways in a natural square (as from the rules of combination it is certain they may) they could not be disposed in a *magic figure* above sixteen different ways; but M. Frenicle showed, that they might be thus disposed 878 different ways: whence it appears how much his method exceeds the former, which only yielded the 55th part of *magic squares* of that of Mr. Frenicle.

To this inquiry he thought fit to add a difficulty, that had not yet been considered: the *magic squares*, of 7, for instance, being constructed, and its 49 cells filled, if the two horizontal ranks of cells, and, at the same time, the two vertical ones, the most remote from the middle, be retrenched, that is, if the whole border or circumference of the square be taken away, there will remain a square, whose root will be 5, and which will only consist of twenty-five cells. Now, it is not at all surprising, that the square should be no longer *magical*, because the ranks of the large ones were not intended to make the same sum, excepting when taken entire with all the seven numbers that fill their seven cells; so that being mutilated each of two cells, and having lost two of their numbers, it may be well expected, that their remainders will not any longer make the same sum. But M. Frenicle would not be satisfied, unless when the circumference or border of the *magic square* was taken away, and even any circumference at pleasure, or, in fine, several circumferences at once, the remaining square were still *magical*: which last condition, no doubt, made these *squares* vastly more magical than ever.

Again, he inverted that condition, and required that any circumference taken at pleasure, or even several circumferences, should be inseparable from the square; that is, that it should cease to be *magical* when they were removed, and yet continue *magical* after the removal of any of the rest. M. Frenicle, however, gives no general demonstration of his methods, and frequently seems to have no other guide but chance. It is true, his book was not published by himself, nor did it appear till after his death, viz. in 1693.

In 1703, M. Poignard, canon of Bruffels, published a treatise of sublime *magic squares*. Before him there had been no *magic squares* made but for feriefes of natural numbers that formed a square; but M. Poignard made two very considerable improvements. 1°, Instead of taking all the numbers that fill a square, for instance, the thirty-six fucceffive numbers, which would fill all the cells of a natural square, whofe fide is 6, he only takes as many fucceffive numbers as there are units in the fide of the fquare, which, in this cafe, are 6; and thefe fix numbers alone he difpofes in fuch manner, in the thirty-fix cells, that none of them are repeated twice in the fame rank, whether it be horizontal, vertical, or diagonal; whence it follows, that all the ranks, taken all the ways poffible, muft always make the fame fum, which M. Poignard calls repeated progreffion. 2°, Inftead of being confined to take thefe numbers according to the feries and fucceffion of the natural numbers, that is, in an arithmetical progreffion, he takes them likewife in a geometrical progreffion, and even in an harmonical progreffion. But with thefe two laft progreffions the *magic* muft neceffarily be different to what it was: in the fquares, filled with numbers in geometrical progreffion, it conſiſts in this, that the products of all the ranks are equal; and, in the harmonical progreffion, the numbers of all the ranks continually follow that progreffion: he makes fquares of each of thefe three progreffions repeated.

This book of M. Poignard gave occafion to M. De la Hire to return his thoughts the fame way, which he did with fuch fuccefs, that he feems to have well-nigh completed the theory of *magic fquares*. He firft conſiders uneven *fquares*: all his predeceffors on the fubject having found the conſtruction of even ones by much the moſt difficult; for which reafon M. De la Hire reſerves thofe for the laſt. This exceſs of difficulty may arife partly from hence, that the numbers are taken in arithmetical progreffion. Now in that progreffion, if the number of terms be uneven, that in the middle has fome properties, which may be of ſervice; for inſtance, being multiplied by the number of terms in the progreffion, the product is equal to the ſum of all the terms.

M. De la Hire propoſes a general method for uneven fquares, which has fome affinitude with the theory of compound motions, ſo uſeful and fertile in mechanics. As that conſiſts in decompounding motions, and reſolving them into others more ſimple; ſo does M. De la Hire's method conſiſt in reſolving the fquare that is to be conſtructed into two ſimple and primitive fquares. It muſt be owned, however, it is not quite ſo eaſy to conceive thoſe two ſimple and primitive fquares in the compound or perfect fquare, as in an oblique motion to imagine a parallel and perpendicular one.

Suppoſe a fquare of cells, whoſe root is uneven, for inſtance 7; and that its forty-nine cells are to be filled magically with numbers, for inſtance, the firſt 7. M. De la Hire, on the one ſide, takes the firſt ſeven numbers, beginning with unity, and ending with the root 7; and on the other 7, and all its multiples to 49, exclufively; and as thefe only make ſix numbers, he adds 0, which makes this an arithmetical progreſſion of ſeven terms, as well as the other; 0. 7. 14. 21. 28. 35. 42. This done, with as the firſt progreſſion repeated, he fills the ſquare of the root 7 magically: in order to this, he writes in the firſt ſeven cells of the firſt horizontal rank, the ſeven numbers propoſed, in what order he pleaſes, for that is abſolutely indifferent; and it is proper to obſerve here, that thoſe ſeven numbers may be ranged in 5040 different manners in the ſame rank. The order in which they are placed in the firſt horizontal rank, be it what it will, is that which determines their order in all the reſt. For the ſecond horizontal rank, he places in its firſt cell, either the third, the fourth, the fifth, or the ſixth number, from the firſt number of the firſt rank; and after that writes the ſix others in order as they follow. For the third horizontal rank, he obſerves the ſame method with regard to the ſecond, that he obſerved in the ſecond with regard to the firſt, and ſo of the reſt. For inſtance, ſuppoſe the firſt horizontal rank filled with the ſeven numbers in their natural order, 1, 2, 3, 4, 5, 6, 7; the ſecond horizontal rank may either commence with 3, with 4, with 5, or with 6: but in this inſtance it commences with 3; the third rank therefore muſt commence with 5; the fourth with 7, the fifth with 2, the ſixth with 4, and the ſeventh with 6. The commencement of the ranks which follow the firſt being thus determined, the other numbers as we have already obſerved, muſt be written down in the order wherein they ſtand in the firſt, going on to 5, 6, and 7 and returning to 1, 2, &c. All every number in the firſt rank be found in every rank underneath, according to the order arbitrarily pitched upon at firſt. By this means it is evident, that no number whatever can be repeated twice in the ſame rank; and by conſequence, that the

1	3	5	4	2	6	7

4	5	6	7	1	2	3
6	7	1	2	3	4	5

seven numbers 1, 2, 3, 4, 5, 6, 7, being in each rank, muſt of neceſſity make the ſame ſum.

It appears, from this example, that the arrangement of the numbers in the firſt rank being choſen at pleaſure, the other ranks may be continued in four different manners: and ſince the firſt rank may have 5040 different arrangements, there are no leſs than 20160 different manners of conſtructing the *magic ſquare* of ſeven numbers repeated.

1	2	3	4	5	6	7

2	3	4	5	6	7	1

The order of the numbers in the firſt rank being determined; if in beginning with the ſecond rank, the ſecond number 2, or the laſt number 7, ſhould be pitched upon, in one of thoſe caſes and repeated; and, in the other caſe, the other diagonal would be falſe, unleſs the number repeated ſeven times ſhould happen to be 4; for four times ſeven is equal to the ſum of 1, 2, 3, 4, 5, 6, 7: and, in general, in every ſquare conſiſting of an unequal number of terms, in arithmetical progreſſion, one of the diagonals would be falſe according to thoſe two conſtructions, unleſs the term always repeated in that diagonal, were the middle term of the progreſſion.

It is not, however, at all neceſſary to take the terms in an arithmetical progreſſion; for, according to this method, one may conſtruct a *magic ſquare* of any numbers at pleaſure, whether they be according to any certain progreſſion, or not. If they be in an arithmetical progreſſion, it will be proper, out of the general method, to except thoſe two conſtructions, which produce a continual repetition of the ſame term, in one of the two diagonals; and only to take in the caſe, wherein that repetition would prevent the diagonal from being juſt: which caſe being abſolutely diſcarded, when we computed, that the ſquare of 7 might have 20160 different conſtructions; it is evident, that by taking that caſe in, it muſt have vaſtly more.

To begin the ſecond rank with any other number beſides the ſecond and the laſt, muſt not, however, be looked on as an univerſal rule: it holds good for the ſquare of 7; but if the ſquare of 9, for inſtance, were to be conſtructed, and the fourth figure of the firſt horizontal rank were pitched on for the firſt of the ſecond, the conſequence would be, that the fifth and eighth horizontal ranks would likewiſe commence with the ſame number, which would therefore be repeated three times in the ſame vertical rank, and occaſion other repetitions in all the reſt. The general rule, therefore, muſt be conceived thus: let the number in the firſt rank pitched on, for the commencement of the ſecond, have ſuch an exponent of its quota, that is, let the order of its place be ſuch, as that if an unit be taken from it, the remainder will not be any juſt quota part of the root of the ſquare; that is cannot divide it equally. If for example, in the ſquare of 7, the third number of the firſt horizontal rank be pitched on for the firſt of the ſecond, ſuch conſtruction will be juſt; becauſe the exponent of the place of that number, viz. 3, ſubtracting 1, that is, 2 cannot divide 7. Thus alſo reckon the fourth number of the ſame firſt rank be choſen, becauſe 4—1, viz. 3, cannot divide 7; and, for the ſame reaſon, the fifth or ſixth number might be taken: but in the ſquare of 9, the fourth number of the firſt rank muſt not be taken, becauſe 4—1, viz. 3, does divide 9. The reaſon of this rule will appear very evidently, by conſidering in what manner the returns of the ſame numbers do or do not happen, taking them always in the ſame manner in any given ſeries. And hence it follows, that the fewer diviſions the root of any ſquare to be conſtructed has, the more different manners of conſtructing it there are; and that the prime numbers, i. e. thoſe which have no diviſions, as 3, 5, 7, 11, 13, &c. are thoſe whoſe ſquares will admit of the moſt variations in proportion to their quantities.

The ſquares conſtructed, according to this method, have ſome particular properties not required in the problem; for the numbers that compoſe any rank parallel to one of the two diagonals, are ranged in the ſame order with the numbers that compoſe the diagonal, to which they are parallel. And as any rank parallel to a diagonal, muſt neceſſarily be ſhorter, and have fewer cells, than the diagonal itſelf, by adding to it the correſpondent parallel, which has the number of cells by which the other falls ſhort of the diagonal, the numbers of thoſe two parallels, placed, as it were, end to end, muſt follow the ſame order with thoſe of the diagonal: beſides, that their ſums are likewiſe equal; ſo that they are magical on another account.

Inſtead of the ſquares, which we have hitherto formed by horizontal ranks, one might alſo form them by vertical ones: the caſe is the ſame in both.

All we have hitherto ſaid regards only the firſt primitive ſquare, whoſe numbers, in the propoſed example, were 1, 2, 3, 4, 5, 6, 7: here ſtill remains the ſecond primitive, whoſe numbers are 0, 7,

Firſt Primitive.

1	2	3	4	5	6	7
3	4	5	6	7	1	2
5	6	7	1	2	3	4
7	1	2	3	4	5	6
2	3	4	5	6	7	1
4	5	6	7	1	2	3
6	7	1	2	3	4	5

14, 21, 28, 35, 42. M. de la Hire proceeds in the ſame manner here as in the former; and this may likewiſe be conſtructed in 20160 different manners, as containing the ſame number of terms with the firſt. Its conſtruction being made, and of conſequence all its ranks making the ſame ſum, it is evident, that if we bring the two into one, by adding together the numbers of the two correſponding cells of the two ſquares, that is, the two numbers of the firſt of each, the two numbers of the ſecond, of the third, &c. and diſpoſe them in the forty-nine correſponding cells of a third ſquare; it will likewiſe be *magical*, in regard to its rank, formed by the addition of equal ſums to equal ſums, which muſt of neceſſity be equal among themſelves. All that remains in doubt is, whether or no, by the addition of the correſponding cells of the two firſt ſquares, all the cells of the third will be filled in ſuch manner, as that each not only contains one of the numbers of the progreſſion from 1 to 49, but alſo that this number be different from any of the reſt, which is the end and deſign of the whole operation.

Second Primitive.

0	7	14	21	28	35	42
21	28	35	42	0	7	14
42	0	7	14	21	28	35
14	21	28	35	42	0	7
35	42	0	7	14	21	28
7	14	21	28	35	42	0
28	35	42	0	7	14	21

As to this it muſt be obſerved, that if in the conſtruction of the ſecond *primitive ſquare*, care has been taken in the commencement of the ſecond horizontal rank, to obſerve an order with regard to the firſt, different from what was obſerved in the conſtruction of the firſt ſquare; for inſtance, if the ſecond rank of the firſt ſquare began with the third term of the firſt rank, and the ſecond rank of the ſecond ſquare commence with the fourth of the firſt rank, as in the example it actually does; each number of the firſt ſquare may be combined once, and only once, by addition with all the numbers of the ſecond. And as the numbers of the firſt are here 1, 2, 3, 4, 5, 6, 7, and thoſe of the ſecond 0, 7, 14, 21, 28, 35, 42, by combining them in this manner, we have all the numbers in the progreſſion from 1 to 49, without having any of them repeated, which is the *perfect magic ſquare* propoſed.

Perfect Square.

1	9	17	25	33	41	42
22	30	38	46	5	13	21
43	2	10	18	26	34	35
14	23	31	39	47	6	7
36	44	3	11	19	27	28
8	16	24	32	40	48	29
49	27	35	36	45	4	12

The neceſſity of conſtructing the two *primitive ſquares* in a different manner, does not at all hinder but that each of the 20160 conſtructions of the one may be combined with all the 20160 conſtructions of the other: of conſequence, therefore 20160 multiplied by itſelf, which makes 406425600, is the number of different conſtructions that may be made of the *perfect ſquare*, which here conſiſts of the 49 numbers of the natural progreſſion. But as we have already obſerved, that a *primitive ſquare* of ſeven numbers repeated may have above 20160 ſeveral conſtructions, the number 406425600 will come vaſtly ſhort of expreſſing all the poſſible conſtructions of a perfect *magic ſquare* of the 49 firſt numbers.

As to the *even ſquares*, he conſtructs them like the uneven ones, by two *primitive ſquares*; but the conſtruction of *primitives* is different in general, and may be ſo a great number of ways: and thoſe general differences admit of a great number of particular variations, which give as many different conſtructions of the ſame even ſquare. It ſcarce ſeems poſſible to determine exactly, either how many general differences there may be between the conſtruction of the primitive ſquares of an even ſquare, and an uneven one; nor how many particular variations each general difference may admit of: and, of conſequence, we are ſtill *fat* from being able to determine the number of different conſtructions of all thoſe that may be made by the primitive ſquares.

See the Memoirs of the Royal Academy of Sciences, for 1705 and 1710, where this ſubject is almoſt exhauſted by M. de la Hire and M. Sauveur. See alſo Saunderſon's Algebra, vol. 2. p. 354, &c.

The ingenious Dr. Franklin ſeems to have carried this

curious speculation farther than any of his predeceſſors in the ſame way. He has conſtructed not only a *magic* ſquare of ſquares, but likewiſe a *magic* circle of circles, of which we ſhall give ſome account for the amuſement of our readers. The *magic* ſquare of ſquares is formed by dividing the great ſquare, as *Tab.* III. *Analyſis, fig.* 64. The great ſquare is divided into 256 ſmall ſquares, in which all the numbers from 1 to 256 are placed, in 16 columns, which may be taken either horizontally or vertically. The properties are as follow:

1. The ſum of the ſixteen numbers in each column, vertical and horizontal, is 2056.

2. Every half column, vertical and horizontal, makes 1028, or half of 2056.

3. Half a diagonal aſcending, added to half a diagonal deſcending, makes 2056; taking theſe half diagonals from the ends of any ſide of the ſquare to the middle thereof; and ſo reckoning them either upward, or downward; or ſidewiſe from left to right hand, or from right to left.

4. The ſame with all the parallels to the half diagonals, as many as can be drawn in the great ſquare: for any two of them being directed upward and downward, from the place where they begin to that where they end, their ſums will make 2056. The ſame downward and upward in like manner: or all the ſame if taken ſideways to the middle, and back to the ſame ſide again.

N. B. One ſet of theſe half diagonals and their parallels, is drawn in the ſame ſquare upward and downward. Another ſuch ſet may be drawn from any of the other three ſides.

5. The four corner numbers in the great ſquare added to the four central numbers therein, make 1028; equal to the half ſum of any vertical or horizontal column, which contains 16 numbers; and equal to half a diagonal or its parallel.

6. If a ſquare hole (equal in breadth to four of the little ſquares) be cut in a paper, through which any of the ſixteen little ſquares in the great ſquare may be ſeen, and the paper be laid on the great ſquare; the ſum of all the 16 numbers, ſeen through the hole, is equal to the ſum of the ſixteen numbers in any horizontal or vertical column, viz. to 2056.

The *magic* circle of circles, *fig.* 65. is compoſed of a ſeries of numbers, from 1 to 75 inclufive, divided into eight concentric circular ſpaces, and ranged in eight radii of numbers, with the number 12 in the center; which number, like the center, is common to all theſe circular ſpaces, and to all the radii.

The numbers are ſo placed, that the ſum of all thoſe in either of the concentric circular ſpaces above mentioned, together with the central number 12, make 360; equal to the number of degrees in a circle.

The numbers in each radius alſo, together with the central number 12, make juſt 360.

The numbers in half of any of the above circular ſpaces, taken either above or below the double horizontal line, with half the central number 12, make 180; equal to the number of degrees in a ſemicircle.

If any four adjoining numbers be taken, as if in a ſquare, in the radial diviſions of theſe circular ſpaces; the ſum of theſe, with half the central number, make 180.

There are, moreover, included four ſets of other circular ſpaces, bounded by circles which are excentric with reſpect to the common center; each of theſe ſets containing five ſpaces. The centers of the circles which bound them are at A, B, C, and D. The ſet whoſe center is at A is bounded by dotted lines; the ſet whoſe center is at C is bounded by lines of ſhort unconnected ſtrokes, and the ſet round D is bounded by lines of unconnected longer ſtrokes, to diſtinguiſh them from one another. In drawing this figure by hand, the ſet of concentric circles ſhould be drawn with black ink; and the four different ſets of excentric circles with four kinds of ink of different colours; as blue, red, yellow, and green, for diſtinguiſhing them readily from one another.

Theſe ſets of excentric circular ſpaces interſect thoſe of the concentric, and each other: and yet, the numbers contained in each of the excentric ſpaces, taken all around through any of the 20, which are excentric, make the ſame ſum as thoſe in the concentric; namely 360, when the central number 12 is added. Their halves alſo, taken above or below the double horizontal line, with half the central number, make 180.

Obſerve, that there is not one of the numbers but what belongs at leaſt to two of the circular ſpaces; ſome to three, ſome to four, ſome to five: and yet they are all ſo placed, as never to break the required number 360, in any of the 28 circular ſpaces within the primitive circle.

To bring theſe matters in view, all the numbers as above mentioned are taken out: and placed in ſeparate columns, as they ſtand around both the concentric and excentric circular ſpaces, always beginning with the outermoſt and ending with the innermoſt of each ſet; and alſo the numbers as they ſtand in the eight radii, from the circumference to the center: the common central number 12 being placed the loweſt in each column.

1. In the eight concentric circular ſpaces.

40	55	33	53	35	
57	31	48	38	50	
12	12	12	12	12	
360	360	360	360	360	

If now, we take any four numbers, as in a ſquare form, either from N° 1. N° 2. (as ſuppoſe from N° 1.) as in the margin; and add half the central number 12 to them, the ſum will be 180; equal to half the numbers in any circular ſpace, taken above or below the double horizontal line; and equal to the number of degrees in a ſemicircle. Thus, 14, 72, 25, 63, and 6, make 180. See Franklin's Eſſays and Obſ. p. 350, &c. edit. 4to. 1769; or Ferguſon's Tables and Tracts, 1771, p. 318, &c.

	6

MAGICAL *picture*, in *Electricity*, was firſt contrived by Mr. Kinnerſley, and is thus made: having a large metzotinto with a frame and glaſs, e. gr. of the king, take out the print, and cut a pannel out of it, near two inches diſtant from the frame all round; with thin paſte or gum-water, fix the border that is cut off on the inſide of the glaſs, preſſing it ſmooth and cloſe: then fill up the vacancy by gilding the glaſs well with leaf gold, or braſs. Gild likewiſe the inner edge of the back of the frame all round,

round, except the top part, and form a communication between that gilding and the gilding behind the glass; then put in the board, and that side is finished. Turn up the glass, and gild the foreside exactly over the back gilding, and when it is dry, cover it, by passing on the pannel of the picture that hath been cut out, observing to bring the correspondent parts of the border and picture together, by which means the picture will appear of a piece, as at first, only part behind the glass and part before. Hold the picture horizontally by the top, and place a little moveable gilt crown on the king's head. If now the picture be moderately electrified, and another person takes hold of the frame with one hand, so that his fingers touch its inside gilding, and with the other hand endeavour to take off the crown, he will receive a terrible blow, and fail in the attempt. If the picture were highly charged, the consequence might be as fatal as that of high treason. The operator, who holds the picture by the upper end, where the inside of the frame is not gilt, to prevent its falling, feels nothing of the shock, and may touch the face of the picture without danger. If a ring of persons take the shock among them, the experiment is called the conspirators. Franklin's Exp. and Obf. p. 30.

MAGICIAN, is one who practifes the art of MAGIC. See DIVINATION and SORCERY.

The ancient *magicians* pretended to extraordinary powers of interpreting dreams, foretelling future events, and accomplifhing many wonderful things, by their fuperior knowledge of the fecret powers of nature, of the virtues of plants and minerals, and of the motions and influences of the ftars. And as the art of magic among the pagan nations was founded in this fyftem of theology, and the *magi* who firft exercifed it were the priefts of the gods, they pretended to derive thefe extraordinary powers from the affiftance of the gods; which affiftance they fought by a great variety of rites and facrifices, adapted to their refpective natures, by the ufe of charms and fuperftitious words, and alfo by ceremonies and fupplications: they pretended likewife, in the proper ufe of their art, to a power of compelling the gods to execute their defires and commands. A late excellent writer has fhewn, that the fcripture brands all thefe powers as a fhameleſs impofture, and reproaches thofe who aſſumed them with an utter inability of difcovering or accomplifhing any thing fupernatural. See Ifaiah xlvii. 11, 12, 13. chap. viii. 18, 19. chap. xii. 23, 24. chap. xliv. 25. Jerom. x. 2, 3, 8, 14. chap. xiv. 14. chap. xxvii. 9, 10. chap. l. 36. Pf. xxi. 6. Jonah ii. 8. Nevertheleſs many of the Chriſtian fathers, as well as fome of the heathen philofophers, aſcribed the efficacy of *magic* to evil DEMONS: and it was a very prevailing opinion in the primitive church, that *magicians* and necromancers, both among the Gentiles and heretical Chriſtians, had each their particular demons, perpetually attending on their perſons, and obſequious to their commands, by whofe help they could call up the ſouls of the dead, foretel future events, and perform miracles. In ſupport of this opinion, it has been alledged, that the names by which the ſeveral ſorts of diviners are deſcribed in ſcripture, imply a communication with ſpiritual beings; that the laws of Moſes (Exod. xxii. 18. Lev. xix. 26, 31. chap. xx. 27. Deut. xviii. 10, 11.) againſt divination and witchcraft, prove the efficacy of theſe arts, though in reality they prove nothing more than their execrable wickedneſs and impiety; and that pretenſions to divination could not have ſupported their credit in all the heathen nations and through all ages, if ſome inſtances of true divination had not occurred. But the ſtrongeſt argument is derived from the ſcripture hiſtory of the *Egyptian magicians* who oppoſed Moſes. With regard to the works performed by theſe *magicians*, ſome have ſuppoſed that God himſelf empowered them to perform true miracles, and gave them an unexpected ſucceſs; but the hiſtory expreſsly aſcribes the effects they produced, not to God, but to their own inchantments. Others imagine, that the devil aſſiſted the *magicians* not in performing true miracles, but in deceiving the ſenſes of the ſpectators, or in preſenting before them deluſive appearances of true miracles: againſt which opinion it has been urged that it tends to diſparage the credit of the works of Moſes. The moſt common opinion ſince the time of St. Auſtin, has been, that they were not only performed by the power of the devil, but were genuine miracles, and real imitations of thoſe of Moſes. In a late elaborate inquiry into the true ſenſe and deſign of this part of ſcripture hiſtory, it has been ſhewn, that the names given to the *magicians*, ſeem to expreſs their profeſſion, their affectation of ſuperior knowlege, and their pretences both to explain and effect ſigns and wonders, by obſerving the rules of their art; and therefore, that they are the perſons, whoſe ability of diſcovering or effecting any thing ſupernatural the ſcripture expreſly denies. The learned author farther inveſtigates the deſign, for which Pharaoh employed them on this occaſion; which, he apprehends, was to learn from them, whether the ſign given by Moſes was truly ſupernatural, or only ſuch as their art was able to accompliſh. Accordingly it is obſerved, that they did not undertake to outdo Moſes, or to control him, by ſuperior or oppoſite arts of power, but merely to imitate him, or to do the ſame works with his, with a view of invalidating the argument which he drew from his miracles, in ſupport of the ſole divinity of Jehovah, and of his own miſſion. The queſtion on this occaſion was not, are the gods of Egypt ſuperior to the God of Iſrael, or can any evil ſpirits perform greater miracles than thoſe which Moſes performed by the aſſiſtance of Jehovah? but the queſtion was, are the works of Moſes proper proofs, that the God of Iſrael is Jehovah, the only ſovereign of nature, and conſequently that Moſes acts by his commiſſion; or, are they merely the wonders of nature, and the effects of magic? In this light Philo, de Vita Moſis, lib. i. p. 616, and Joſephus, Antiq. Jud. lib. ii. cap. 13. place the ſubject. Moreover, it appears from the principles and conduct of Moſes, that he could not allow the *magicians* to have performed real miracles: becauſe the ſcripture repreſents the whole body of *magicians* as impoſtors; the ſacred writers, Moſes in particular, deſcribe all the heathen deities, in the belief of whoſe exiſtence and influence the magic art was founded, as unſupported by any inviſible ſpirits, and merely impotent and fenſeleſs: the religion of Moſes was built on the unity and ſole dominion of God, and the ſole divinity of Jehovah was the point which Moſes was now about to eſtabliſh, in direct oppoſition to the principles of idolatry; ſo that if he had allowed that the heathen idols, or any evil ſpirits ſupporting their cauſe, enabled the *magicians* to turn rods into ſerpents, and water into blood, and to create frogs, he would have contradicted the great deſign of his miſſion, and overthrown the whole fabric of his religion: beſides, Moſes appropriates all miracles to God, and urges his own, both in general and ſeparately, as an abſolute and authentic proof, both of the ſole divinity of Jehovah, and of his own miſſion; which he could not juſtly have done, if his oppoſers performed miracles, and even the ſame with his. On the other hand, it has been urged, that Moſes deſcribes the works of the *magicians* in the very ſame language he does his own. Exod. vii. 11, 12. chap. v. 22. chap. viii. 7. and hence it is concluded, that they were equally miraculous. To this objection it is replied, that it is common to ſpeak of profeſſed jugglers, as doing what they pretend and appear to do; but that Moſes does not affirm, that there was a perfect conformity between his works and thoſe of the *magicians*, but they did *ſo*, or in like manner, uſing a word which expreſſes merely a general ſimilitude; and he expreſſly refers all they did, or attempted in imitation of himſelf, not to the invocation or power of demons, or of any ſuperior beings, but to human artifice and impoſture. The original words tranſlated *inchantments*, Exod. vii. 11. 22. and chap. viii. 7, 18. import deception and concealment, and ought to have been rendered, *ſecret ſlights* or *jugglings*. Our learned writer farther ſhews, that the works performed by the *magicians* did not exceed the cauſe, or human artifice, to which they are aſcribed. Farmer's Diſſ. on Miracles, 1771, chap. 3. ſ. 3. chap. 4. ſ. 1.

MAGISTER, MASTER, a title frequently found in old writings; noting the perſon who bore it to have attained ſome degree of eminence *in ſcientia aliqua, præſertim in literaria*.

In old times, thoſe we now call *doctors*, were called *magiſtri*, or *maſters*.

MAGISTERY, MAGISTERIUM, in *Chemiſtry*, is a name given to almoſt all precipitates; ſo that *magiſtery* and precipitate are almoſt ſynonymous: but the term has been lately applied to ſome particular precipitates, which are uſed in medicine and the arts. Such are the *magiſteries* of biſmuth, coral, crabs-eyes, ſulphur, &c.

MAGISTERY *of biſmuth*, is a fine powder, made by diſſolving biſmuth in ſpirit of nitre, and pouring on it a large quantity of clear water, which precipitates the *magiſtery* to the bottom.

This is chiefly uſed in the compoſition of white paint for the ladies: it is preferred to all other whites on account of its ſuperior beauty, luſtre, and almoſt inſenſible tint of carnation, which renders it more ſimilar to the fineſt and whiteſt ſkin; but the ſkin will be conſiderably injured by a continued uſe of it. See BISMUTH.

MAGISTERY *of coral*, &c. Coral, crabs-eyes, pearl, ſhells, chalk, and other ſubſtances of that kind, are all abſorbent and calcareous earths, eaſily ſoluble in nitrous acid. If the ſolutions of theſe matters are precipitated by a fixed alkali, and afterwards well waſhed, they acquire the name of *magiſtery*, together with that of the ſubſtance which has been diſſolved and precipitated.

MAGISTERY *of lead*. See LEAD.

MAGISTERY is alſo uſed in ſpeaking of reſins, or the reſi-

nous

roots extracts of scammony, jalap, turbith, &c. which are made by drawing a tincture from the matter in spirit of wine, and precipitating it with water.

Mr. Boyle takes the proper notion of a *magistery* to consist in a preparation of a body, whereby it is wholly, or in part, reduced into a finer consistence, by means of some extraneous *adjutament*, converted into a body of a different kind: as when iron or copper is turned into crystals of Mars and Venus.

MAGISTRATE, is the name of any public officer or ruler, to whom the executive power of the law is committed, either wholly or in part. Of *magistrates*, some are supreme, in whom the sovereign power of the state resides; others are subordinate, deriving all their authority from the supreme *magistrate*, accountable to him for their conduct, and acting in an inferior secondary sphere. See KING, SHERIFF, JUSTICE, &c.

MAGMA, *Marc*, among *Chymists*, &c. the dregs or recrement of a composition, remaining after all the more fluid parts are expressed.

It is a word used by medical writers on many occasions, sometimes in a very lax, and sometimes in a more appropriated sense. Some writers use it to express a mass of any thing; others for a thick ointment made up with very little fluid matter to prevent its running; and others for the remains of an ointment after expression from its ingredients. Galen restrains the word *magma* to express only the feces of mitobalans.

MAGNA *arteria*. See AORTA.

MAGNA *assisa elisenda*, a writ directed to the sheriff to summon four lawful knights before the justices of assise, there, upon their oaths, to choose twelve knights of the vicinage, &c. to pass upon the *great assise* between A. B. plaintiff, and C. D. defendant, &c. See ASSISE.

MAGNA *Charta*, the *great charter* of liberties of England, granted in the ninth year of Henry the Third, and confirmed by Edward the First.

The reason of it's being termed *Magna*, or *great*, is either because of the excellency of the laws and liberties therein contained; or because there was another charter, called *Charta de Foresta*, established with it, which was the less of the two; or else because it contained more than any other charters; or in regard of the wars and troubles in the obtaining of it; or of a great and remarkable solemnity in the denouncing excommunications against the infringers of it.

Magna Charta may be said to derive its origin from king Edward the Confessor, who granted divers liberties and privileges, both civil and ecclesiastical, by charter: the same, with some others, were also granted and confirmed by king Henry I. by a celebrated great charter, now lost. His successors king Stephen, king Henry II. and king John, confirmed or re-enacted the same; but the last prince violating his charter, the barons took up arms, and his reign ended in blood. Henry III. who succeeded him, after having procured an inquisition to be made by twelve men in each county, what the liberties of England were in the time of Henry I. confirmed, with some alterations, the charter, obtained sword in hand from king John, in 1215, being the present *Magna Charta*; which he several times confirmed, and as often broke again; till, in the thirty-seventh year of his reign, he came to Westminster-hall; where, in the presence of the nobility and bishops, with lighted candles in their hands, *Magna Charta* was read, the king all the while laying his hand on his breast, and at last solemnly swearing faithfully and inviolably to observe all the things therein contained, as he was a man, a Christian, a soldier, and a king. Then the bishops extinguished their candles, throwing them on the ground, crying, Thus let him be extinguished and blak in hell who violates this charter.

Nevertheless, king Henry in the next year invaded the rights of his people, till the barons levied war against him; and, after various success, he confirmed this charter and the charter of the forest, in the parliament of Marlebridge, and in the fifty-second year of his reign. Afterwards, by the statute 25 Edw. I. called *confirmatio cartarum*, whereby the great charter is directed to be allowed as the common law, all judgments contrary to it are declared void; copies of it are ordered to be sent to all cathedral churches, and read twice a year to the people; and sentence of excommunication is directed to be as constantly denounced against all those that, by word, deed, or counsel, act contrary thereto, or in any degree infringe it. Sir Edward Coke observes, that it was confirmed no less than thirty-two times, from the fifth Edward to Henry IV. Then, after a long interval, by the *petition of* RIGHT, by many salutary laws, particularly the HABEAS *corpus act* of Charles II. by the *bill of* RIGHTS, and lastly by the *act of* SETTLEMENT.

The *Magna Charta* is the basis of the English laws and liberties: besides those provisions, which redressed many grievances incident to feodal tenures, care was also taken therein to protect the subject against other oppressions, frequently arising from unreasonable amercements, from illegal distresses or other process for debts or services due to the crown, and from the tyrannical abuse of the prerogative of purveyance, and pre-emption. It fixed the forfeiture of lands for felony in the same manner as it still remains; prohibited for the future the grants of exclusive fisheries, and the erections of new bridges so as to oppress the neighbourhood. With respect to private rights, it established the testamentary power of the subject over part of his personal estate, the rest being distributed among his wife and children: it laid down the law of dower, as it hath continued ever since; and prohibited the appeals of women, unless for the death of their husbands. In matters of public police and national concern: it enjoined an uniformity of weights and measures; gave new encouragement to commerce, by the protection of merchant-strangers; and forbad the alienation of lands in mortmain. With regard to the administration of justice: besides prohibiting all denials or delays of it, it fixed the court of Common Pleas at Westminster, that the suitors might no longer be harassed with following the king's person in all his progresses; and at the same time brought the trials of issues home to the very doors of the freeholders, by directing assizes to be taken in the proper counties, and establishing annual circuits; it also corrected some abuses then incident to the trials by wager of law and of battle; directed the regular awarding of inquests for life or member; prohibited the king's inferior ministers from holding pleas of the crown, or trying any criminal charge, whereby many forfeitures might otherwise have unjustly accrued to the Exchequer; and regulated the time and place of holding the inferior tribunals of justice, the county-court, sheriff's turn and court-leet. It confirmed and established the liberties of the city of London, and all other cities, boroughs, towns, and ports of the kingdom. And, lastly, (which alone would have merited the title that it bears of the *Great Charter*) it protected every individual of the nation in the free enjoyment of his life, his liberty, and his property, unless declared to be forfeited by the judgment of his peers or the law of the land. Blackst. Com. vol. iv. p. 417.

MAGNANINE, in *Ornithology*, the name of a small bird described by Aldrovand, Gesner, and some other authors, and seeming to be the same with our *hedge-sparrow*, commonly known among authors by the name *curruca*.

MAGNES *carneus*, in *Natural History*, a name given by Cardan, and some other authors, to a white earth dug in Italy and some other places, and called also by many CALAMITA *alba*. It is an indurated earthy substance of the hardness of otter-stone, and is of a white colour variegated with black lines. It adheres very firmly to the tongue, and is hence said to attract flesh in the same manner as the magnet does iron. It is even pretended, that if an iron stylus be rubbed over with this stony earth, and then plunged into the flesh, the virtue of the earth will heal the wound as soon as made, and when the weapon is taken forth, there will remain no appearance of hurt. Cardan affirms that he saw this tried with success, but suspects witchcraft in the case!

MAGNESIA *alba*, in *Chymistry* and *Medicine*, a fine white earth, which has not hitherto been found naturally pure or in a separate state. At Rome it bore the name of the Count of Palma, though many are of opinion, that the preparation was carried from Germany into Italy. It was, however, for several years, a celebrated secret, in possession of some particular persons, till the method of preparing it was made public by Lancisi, in the year 1717, and afterwards by Hoffman in 1722. It was then extracted from the mother-ley, or the liquor which remains after the crystallization of rough nitre; either by precipitation with a solution of fixed alcaline salts; or by evaporating the liquor, and calcining the dry residuum, so as to dissipate the acids by which the earth had been made soluble. The *magnesia*, in this mother-ley, proceeds from the vegetable ashes contained in it; but as quick-lime is commonly much employed in most of the German, French, and other European nitre-works, the substance obtained from the mother-leys of those works, is rather a calcareous earth than *magnesia*, and appears to be such by its burning into quick-lime, and forming a selenites with the vitriolic acid. *Magnesia* is called the *nitrum vitriolatum*, because from two pellucid liquors a coagulum is formed, which contains this substance.

From the experiments of Dr. Black, related in the Edinburgh Phys. & Lit. Ess. vol. ii. art. 8. we learn, that *magnesia* is soluble, with effervescence, in vitriolic, nitrous, marine, and acetous acids; forming with the vitriolic acid crystals, similar to those of the Epsom salt; and with the nitrous acids, crystals which deliquiated in a moist air: with marine acid it formed no crystals; but the saline matter being evaporated to dryness, soon deliquiated

liquiated by expoſure to air: with diſtilled vinegar it formed no cryſtals by evaporation, but a ſaline maſs, viſcid when warm, reſembling glue in colour and conſiſtence, and brittle when cold. *Magneſia* was found to loſe, by calcination, ſeven-twelfths of its weight, and was thus deprived of the power of effervefcing with acids; whence the ſubſtance loſt by calcination was GAS, or *fixable* AIR: nevertheleſs this gas, and almoſt the whole weight loſt by calcination, were reſtored to it by ſolution in vitriolic acid, and precipitation from them by a mild fixed alkali, the gas of which it abſorbed: in this laſt reſpect it ſeemed analogous to the calcareous earths, but differed from them in other properties; particularly in theſe, that when calcined, it was not ſoluble in water, nor communicated any ſenſible impregnation to it, and that it did not, like them, when calcined, become cauſtic or acrid.

Dr. Black alſo found, that *magneſia* was precipitated from acids by volatile alkali; that, when uncalcined, it precipitated calcareous earth from acids; but when calcined, or in any other way deprived of its gas, it did not precipitate theſe earths: when uncalcined, or united with gas, it precipitated lime from lime-water: which ſhews that the calcareous earth had a ſtronger power to combine with the gas, than the *magneſia* had, ſince the former earth took this gas from the latter; by which means the former was rendered ſolid and inſoluble in water, and therefore was precipitated. This property ſuggeſted to Dr. Alſton a method of procuring ſweet water at ſea, by adding *magneſia* to water, the putrefaction of which has been prevented by the previous addition of quick-lime. M. Monnet obſerves, that *magneſia* combined with ſulphur, generally inveſops ſtrata of coal: M. Margraaf has diſcovered that the ſerpentine earths in Saxony, contain *magneſia*: and M. Monnet adds, that the marly and alſo the alum earths contain it. Mr. Henry, aningenious apothecary at Mancheſter, has communicated the following proceſs for making the *magneſia*. Diſſolve any quantity of ſal cathartici amari in its own weight of water; filter and add to it by degrees a filtered ſolution of pearl or pot-aſhes, in an equal quantity of water, ſtirring them gently, until the mixed liquors have acquired the appearance of a complete coagulum; then deſiſt from adding any more of the alkaline lixivium, and immediately throw the mixture into a large veſſel of boiling water; keep it boiling for a quarter of an hour, then take it out, and put it into glazed earthen veſſels; as ſoon as the powder hath ſubſided, and before the water is quite cold, pour it off, and add a freſh quantity of boiling water; repeat theſe ablutions with hot water ſeveral times, till the liquor hath entirely loſt its ſaline taſte: then let it be ſo agitated as to ſuſpend the finer parts of the powder, in which ſtate decant it into other veſſels, and having ſeparated the water from the *magneſia*, by inclination, put it on large chalk-ſtones, till a conſiderable part of the humidity is abſorbed; then wrap it up in ſheets of white-paper, and dry it before the fire. Pour hot water upon the remaining powder, ſtir and decant it in its turbid ſtate, and ſeparate the *magneſia* from the water as before; thus the whole, or moſt of it, will be reduced to an equal degree of fineneſs. The larger the quantity of water into which the precipitated powder is caſt, the more ſpeedily and perfectly will the vitriolated tartar, which is formed by the union of the alkali with the acid of the ſal cath. be waſhed off. The neutral ſalt ſhould be waſhed off as quick as poſſible; otherwiſe, by allowing the mixture to ſtand for ſome time, the powder concretes into minute grains, which, when viewed with a microſcope, appear to be aſſemblages of needles diverging from a point. Theſe concretions cannot be re-diſſolved by any waſhing, however long continued. Dr. Black orders four times the quantity of water to that of the ſolution for throwing the coagulum into, but Mr. Henry obſerves, that this quantity is much too little. The water ſhould be pure, and diſtilled water is the beſt, provided it be kept till its empyreuma is gone off. Hard or impure water makes *magneſia* coarſe and diſagreeable. The chalk-ſtones on which the *magneſia* is dried ſhould be expoſed to a moderate heat, that the moiſture may evaporate quickly: and cleanlineſs ſhould be particularly attended to through the whole proceſs.

The *magneſia* is recommended by Hoffman, as an uſeful antacid, a ſafe and inoffenſive laxative in doſes of a dram or two, and a diaphoretic and diuretic, when given in ſmaller doſes of fifteen or twenty grains. It is now much in uſe, particularly in heart-burns, for correcting acidities in the prime viæ, and for preventing or removing the many diſorders to which children are ſubject on this account. It is preferred to all common abſorbents, on account of its laxative quality, which it manifeſts when it meets with an acid in the ſtomach and bowels. If it is mixed with rhubarb, it prevents the rhubarb from leaving a coſtiveneſs behind. If the *magneſia* is neither accompanied, nor met with by an acid, it is not purgative, but ſimply abſorbent.

Objection has been made to the uſe of *magneſia* by Hoffman and others, that it frequently produced flatulencies, gripings and other uneaſy ſenſations, particularly in weak bowels. It is now well known, that theſe ſymptoms muſt have been produced by the great quantity of fixed air contained in it, and diſcharged from it in conſequence of its meeting and effervefcing with an acid in the ſtomach or inteſtines. Dr. Percival, therefore, ſuggeſted to Mr. Henry the idea of depriving it of its air, with a view of obviating theſe troubleſome ſymptoms occaſionally attending the uſe of it. For this purpoſe the *magneſia* ſhould be calcined by putting it in a common crucible, placing it in a glowing fire and keeping it red-hot for the ſpace of two hours. The *magneſia* thus treated was found to be equally purgative, when given in half an former doſe, and is deprived, by this proceſs, of the diſagreeable qualities above mentioned, and acquires likewiſe new properties, which render it likely to anſwer ſome other important practical purpoſe. By calcination it is not only rendered incapable of generating air in the ſtomach and bowels, but it is qualified to abſorb, or render fixed, that which it finds there, and which is produced, ſometimes in too great quantities, in the proceſs of digeſtion; and it is conſequently adapted to relieve thoſe colics or other diſorders, which are commonly called flatulent. In this reſpect it promiſes, as Mr. Henry obſerves, to be much more efficacious than the whole tribe of carminatives, from which it eſſentially differs with regard to its mode of operation and effects. It appears likewiſe to be the moſt proper cathartic for patients afflicted with the ſtone, who are under a courſe of the ſoap-ley; as it cannot, like the vegetable purgatives, counteract the lixivium, by throwing air into it; but, on the contrary, muſt abſorb a part of that air, which is already in the *primæ viæ*, and which would otherwiſe be attracted by the cauſtic alkali and render it leſs capable of acting on the calculus. In order to produce theſe effects, it is of great importance, that the *magneſia* intended for calcination, ſhould be perfectly free from any admixture of calcareous earth; as in that proceſs, this laſt mentioned ſubſtance muſt neceſſarily be deprived of its air, or rendered cauſtic; and the *magneſia* which contains it will accordingly impregnate the water in which it is infuſed with the taſte and qualities of lime-water. Mr. Glaſe's *magneſia*, which has been ſo highly extolled, appears by Mr. Henry's experiments, to contain no inconſiderable portion of calcareous earth. Lond. Med. Tranſ. vol. ii. art. 16. Henry's Exp. and Obſ. 1773.

MAGNESIA *nigra*, or MANGANESE, is a native mineral found in iron mines, and in the lead mines of Mendip-hills, in Somerſetſhire, commonly conſidered as an ore of iron, though the experiments of Mr. Pott and Mr. Cronſtedt ſhew, that it contains little or no iron; and therefore, the latter author has made a diſtinct order of this earth, which he calls *terræ magnæ*. From ſome experiments of the former writer, it may be preſumed that this mineral conſiſts in great part of an earth, analogous to that of alum, which, in combination with acids, makes one of the ſtrongeſt ſyptics.

It is a denſe ponderous ſubſtance, in its fineſt and pureſt pieces, approaching greatly to the texture of the *lapis hæmatites*, being compoſed of regular parallel ſtriæ, diverging from a center to the circumference. This kind, however, is rare; beſide which there is another ſomewhat leſs pure kind, of an iron grey colour, and irregularly ſtreaked like the ſteel-grained lead-ores. But the common *manganeſe* is of a perfectly irregular ſtructure. It is very heavy, moderately hard, and of a deep duſky grey, approaching to black, though ſometimes of a ferruginous brown. It is found in large maſſes of no determinate ſhape, and of a rude, rugged, and unequal ſurface. *Manganeſe* gives fire but difficultly with ſteel, and makes no effervefcence with acids; though they diſſolve ſome part of it, eſpecially when it is calcined. Spirit of vitriol acquires from it a roſe colour; and aqua regia, alſo acquires colour, eſpecially from the black kind. From theſe ſolutions, fixed alkali precipitate a white earth. It is remarkable for communicating to a large proportion of glaſs in fuſion, a purpliſh or red tinge, which diſappears on a continuance of the fire; at the ſame time deſtroying the effects of many other colouring matters, and rendering foul or coloured glaſs clear. When fuſed with nitre or with fixed alkali, it gives to warm water various colours, green, purple, red, or blue, which change by agitating the water. Cronſtedt ſays, that he has ſometimes extracted a ſmall portion of tin from *magneſia*; and that the colours given by it to glaſs, are eaſily deſtroyed by calxes of arſenic or of tin.

Dr. Prieſtley, on putting an ounce of this ſubſtance finely powdered into a ſmall retort with a very long narrow neck, and expoſing it to a red hot heat, found,

that forty ounce measures of air were expelled from it in different portions. Part of this air in every portion, was fixed air, and at firſt almoſt wholly ſo; but four-fifths of the laſt produce was the pureſt dephlogiſticated air. Imagining that the nitrous acid, or at leaſt the influence of the atmoſphere, was neceſſary to the production of this latter kind of air, he was ſurpriſed at this reſult, from examining a ſubſtance, without the uſe of any nitrous acid, which, till it was dug out of the bowels of the earth, had not been expoſed to the influence of the external air; unleſs, as an ingenious writer ſuggeſts, we recur to ſome unknown and very diſtant æra, in which it may poſſibly have had a communication with the atmoſphere, and have acquired its dephlogiſticated air, in a manner ſimilar to that in which the precipitate per ſe, and red lead, at preſent acquire their pure air, during the act of calcination, in our laboratories. According to this idea, we may ſay that *manganeſe*, whoſe nature is little known, may probably be a metallic calx, which has undergone a calcination in volcanos, long ſince extinct; but which may formerly have had a communication with the atmoſphere. Prieſtley's Exp. and Obſ. relating to various Branches of Natural Philoſophy, 1779, p. 203, &c.

From ſome experiments of M. Sage, related in his Elemens de Mineralogie Docimaſtique, &c. Paris, 1777, he is led to infer, that *manganeſe* is compoſed of zinc and cobalt mineraliſed by the marine acid; and he obſerves, that the lead, copper, or iron, which are ſometimes found in it, are accidental additions. He accounts for the quality which this ſubſtance poſſeſſes of deſtroying the bluiſh or green tinge which glaſs may have received, and rendering it colourleſs, by obſerving, that the depuration of the glaſs is probably produced by the calx of the zinc contained in the *manganeſe*: this calx, he ſuppoſes, lays hold of the phlogiſton to which the glaſs owed its green colour. The zinc is thereby reduced, and diſſipated in the atmoſphere, while the ſmall portion of cobalt contained in the *manganeſe* gives the glaſs a ſlight bluiſh tinge, which contributes to its tranſparency.

This ſubſtance is of vaſt uſe in the glaſs-trade, but neither the induſtrious Neri, nor any others who have written of the art, can ever deliver the true proportions in which it is to be mixed with the glaſs-metal on the ſeveral occaſions. The ſame thing is alſo to be obſerved in regard to *zaffer*, another ſubſtance in continual uſe with them. And the reaſon of this is, that there is vaſt difference in the quality of theſe bodies, ſome of which are ſold being very pure and rich, others good for almoſt nothing, and much of middle degrees of purity between theſe. For this reaſon there is no determining how much of each is to be added to the glaſs, but the conciliator adds them at ſeveral times and in ſmall quantities, and takes frequent proofs by his eye, till he knows they are properly proportioned. See GLASS.

It is alſo uſed to give a GLAZING to pottery, and recommended medicinally, when calcined by a ſtrong fire, as an aſtringent.

MAGNESIA, *ſpatina*, *ſpatin*, or ruby coloured *magneſia* of antimony, is made, according to the directions of Lemery, of equal parts of antimony, nitre, and decrepitated ſea-ſalt. It is a much weaker emetic than the liver of *antimony*.

MAGNET, MAGNES, the *loadſtone*; a ſort of ferruginous ſtone, in weight and colour reſembling iron ore, and very hard and heavy; endued with divers extraordinary properties, attractive, directive, inclinatory, &c.

The *magnet* is alſo called *lapis Heraclaeus*, from Heraclea, a city of Magneſia, a port of the ancient Lydia, where it is ſaid to have been firſt found, and from which it is uſually ſuppoſed to have taken its name. Though others derive the word from a ſhepherd named *Magnes*, who firſt diſcovered it with the iron of his crook on mount Ida. It is alſo called *lapis nauticus*, by reaſon of its uſe in navigation; and *ferrites*, from its attracting iron, which the Greeks called σιδηρος.

The *magnet* is indeed a true iron ore, from which a conſiderable portion of iron may be extracted, and is uſually found in iron mines, and ſometimes in very large pieces, half *magnet*, half common ore. Its colour is different, white, blue, red, black, but moſtly ferruginous, according to the different countries it is brought from. Norman obſerves, that the beſt are thoſe brought from China and Bengal, which are of an iron or ſanguine colour; thoſe of Arabia are reddiſh; thoſe of Macedonia blackiſh; and thoſe of Hungary, Germany, England, &c. of the colour of unwrought iron. Neither its figure nor bulk are determined, but it is found of all forms and ſizes.

The ancients reckoned five kinds of *magnets*, different in colour and virtue; the Ethiopic, Magneſian, Bœotic, Alexandrian, and Natolian. They alſo took it to be of two kinds, male and female; but the chief uſe they made of it was in medicine; eſpecially for the cure of burns and defluxions on the eyes. The moderns, more happy, take it to conduct them in their voyages.

The moſt diſtinguiſhing properties of the *magnet* are, that it attracts iron, thus ſerving the purpoſes of the chemiſt in diſcovering or ſeparating ſmall particles of iron, mixed with other matters, and that it points to the poles of the world; and, in other circumſtances, alſo dips or inclines to a point beneath the horizon, directly under the pole; and that it communicates theſe properties, by touch, to iron. On which foundation are formed the mariners needles; both the horizontal, and the inclinatory, or dipping needles. See NEEDLE, DIPPING, &c.

MAGNET, *the attractive power of the*, was known to the ancients, and is mentioned even by Plato and Euripides, who call it the *Herculean ſtone*; becauſe it commands iron, which ſubdues every thing elſe. This property is finely deſcribed by Pliny: *Quid lapidis rigore pugnius? Ecce ſenſus manu ſpe tributi illi natura. Quid ferro durius pugnacius? Sed audit & potitur mores: trahitur namque a magnete lapide, domiteque illa rerum omnium materia ad inane ſeſe quid curret, atque ut proprius venit, aſſiſtit tenaturque, & complexu hæret.* lib. xxxvi. cap. 16.

The ancients ſeem alſo to have been acquainted with the communicative virtue of the *magnet*. Plato has deſcribed a chain of iron rings ſuſpended by one another, the firſt of which is ſuſtained by the load-ſtone: Lucretius, Philo, Pliny, Galen, and Nemeſius have likewiſe deſcribed the ſame phenomenon: but the knowledge of its directive power, whereby it diſpoſes its poles along the meridian of every place, and occaſions needles, pieces of iron, &c. touched with it, to point nearly north and ſouth, is of a much later date; though the exact time of its diſcovery, and the diſcoverer himſelf, are yet in the dark. The firſt tidings we hear of it, are in 1260, when Marco Polo, the Venetian is ſaid, by ſome, to have introduced the mariner's compaſs; though not as an invention of his own; but as derived from the Chineſe, who are ſaid to have had the uſe of it long before: though ſome imagine, that the Chineſe before that had borrowed it from the Europeans.

Flavio de Gioia, a Neopolitan, and a citizen of Amalfi, is the perſon uſually ſuppoſed to have the beſt title to the diſcovery, about the year 1302: and yet Sir G Wheeler mentions, that he had ſeen a book of aſtronomy much older, which ſpoke of the uſe of the needle; though not as applied to the uſes of navigation, but of aſtronomy. And in Guyot de Provins, an old French poet, who wrote about the year 1180, there is expreſs mention made of the *loadſtone*, and the compaſs; and their uſe in navigation is obliquely hinted at.

MAGNET, *the variation of the*, or its declination from the pole, was firſt diſcovered by Seb. Cabot, a Venetian, in 1500, who firſt ſerved our king Henry VII. then the king of Spain, and laſtly returning to England, was conſtituted grand pilot by king Edw. VI. with an annual ſalary of above 166*l.* though Ferdinand, the ſon of Columbus, aſſerts, that his father obſerved it on the 14th of September, 1492: and the variation of that variation by Mr. Gellibrand, an Engliſhman, who publiſhed his diſcovery in a ſmall quarto pamphlet, intitled A Diſcourſe Mathematical on the Variation of the Magnetic Needle, printed in 1635.

Laſtly, the dip or inclination of the needle, when at liberty to play vertically, to a point beneath the horizon, was firſt diſcovered by another of our countrymen, Mr. R. Norman, who in 1581, publiſhed the diſcovery he had long before made, in a ſmall pamphlet, called the *New Attractive*, where he ſhews how to determine its quantity. See DIPPING-*needle*.

MAGNET, *phenomena of the*. 1. In every *magnet* there are two poles, one whereof points northward, the other ſouthward; one of theſe is called the north pole, and the other the ſouth; and that is generally, and moſt properly be called the ſouth pole, which, if the *magnet* was put into a little boat of wood, or other materials, large enough to ſupport it, and ſet aſloat in water, would turn itſelf towards the north; and that is more properly called the north pole, which would turn towards the ſouth. The reaſon of calling them thus is, that the pole of the *magnet* which turns towards the ſouth, is of the ſame kind with the northern magnetic pole or poles of the earth, and contrarywiſe. The north pole of one *magnet* always attracts the ſouth pole, and repels the north pole of another, and *vice verſâ*. It is obſerved that the poles of *magnets* are not at their extremities but at a little diſtance from thence: and if the *magnet* be divided into ever ſo many pieces, the two poles will be found in each piece: we may add, that in ſome natural *magnets* there are more than two poles, inſtances having occurred of ſome in which there are eight, nine, and even ten. M. Muſchenbroeck ſays, that he has ſeen a cube, each ſide of which

was

was polar. The axis of a *magnet* is a right line which paſſes from one pole to another, and the equator is formed by a plane biſecting it in a direction perpendicular to the axis. By the following method, the ſituation of the poles, and the direction of the *magnetic* effluvia in paſſing out of the ſtone, may be exhibited to the ſight: let AB, CD, *Tab. Magnetiſm, fig.* 1. be the poles of the ſtone; about every ſide gently ſtrew ſome fleel-filings on a ſheet of white paper; theſe ſmall particles will be affected by the effluvia of the ſtone, and ſo diſpoſed as to ſhew the courſe and direction of the *magnetic* particles in every part. Thus in the middle of each pole between AB, and DC, it appears to go nearly ſtrait on; towards the ſides it proceeds in lines more and more curved, till at laſt the curve lines from both poles exactly meeting and coinciding form numberleſs curves on each ſide, nearly of a circular figure, as repreſented in the diagram. This ſeems to ſhew, that the *magnetic* virtue emitted from one pole circulates to and enters the other. The ſituation of the poles may be alſo determined by placing over the *magnet* a very fine needle, which will ſtand perpendicular over each pole, being more ſtrongly attracted by it, and no where elſe. 2. Theſe poles, in different parts of the globe, are differently inclined towards a point under the horizon. 3. Theſe poles, though contrary to one another, do help mutually towards the *magnet*'s attraction and ſuſpenſion of iron. 4. If two *magnets* be ſpherical, one will turn or conform itſelf to the other, ſo as either of them would do to the earth; and after they have ſo conformed or turned themſelves, they will endeavour to approach or join each other; but if placed in a contrary poſition, they will avoid each other. This property may be illuſtrated by placing two *magnets* on ſmall pieces of wood, formed in the ſhape of boats, and ſwimming freely on ſtagnated water, undiſturbed by wind, and at ſuch a diſtance as to be within the ſphere of each other's activity: both the boats will ſwim towards each other with an accelerated motion, and meet exactly in the middle of the diſtance between them, provided that the boats and magnets were exactly of the ſame weight and bulk: but if either boat be turned, ſo that its *magnet* may preſent a contrary end to that by which it was attracted by the other *magnet*, they will both recede from each other with an equal velocity. The ſame phenomenon may likewiſe be exhibited by ſuſpending a *magnet* C, from the end B of a balance, *Tab. Magnetiſm, fig.* 2. and forming an equilibrium with a weight in the ſcale A; place another *magnet* D under C, and C will be found to ruſh towards D, and to lift the weight in the ſcale A: but if the oppoſite end of D be preſented to C, C will be repelled by it, aſcend, and the ſcale A will deſcend: if D be placed above C, as in E, the effects will be juſt the contrary.

M. Muſchenbroeck has found by a variety of experiments, that two *magnets* attract one another with different forces at different diſtances; that they act moſt ſtrongly in mutual contact, in which caſe their force has been equal to the weight of three hundred and forty grains, but at the diſtance of twelve inches, equal only to twenty-three grains: nevertheleſs they obſerve no regular proportion in their decreaſe, but their ratio is leſs than the inverſe of their diſtances; and different in different *magnets* and at different times. There are ſome whoſe ſphere of activity reaches even to fourteen feet, and others in which it is not ſenſible at the diſtance of eight or nine inches. He has alſo found, that the ſphere of repulſion varies in different *magnets*, and at different diſtances; and that the repulſive force is much leſs than that of attraction; the latter in contact being equal to three hundred and forty grains, whereas the former is equal only to forty-four grains. It appears alſo from another experiment of the ſame author, that the repelling forces of both poles of the ſame *magnet*, are very conſiderable at the diſtance of twelve lines, being equal to thirty grains, that they increaſe to the diſtance only of ſeven lines, where they are equal to thirty-ſix, but that in immediate contact they are equal only to thirteen grains. Mr. Michell, however, differs much in his concluſions from thoſe above mentioned: he maintains, that each pole acts, attracts, or repels exactly equally, at equal diſtances, in every direction: and that the magnetical attraction and repulſion are exactly equal to each other. He adds, that the miſtake of thoſe who think otherwiſe, ariſe from their not attending to the different degrees of ſtrength, which *magnets* have in different circumſtances: for two *magnets* that are placed with their attracting poles towards each other, will have their power, by that means, increaſed: and, on the contrary, if their repelling poles be placed towards each other, their power will thereby be diminiſhed: and this increaſe or diminution of power will be in a greater or leſs degree, according as the *magnets* are nearer to, or farther from each other: whence in all the experiments made on this ſubject, the attraction and repulſion come perpetually nearer to an equality, the greater the diſtance of the two *magnets* is, with which the experiments are made, and *vice verſa*. And ſo great is the effect of *magnets* on each other, that, when the repellent poles of a large *magnet* and a ſmall one are brought into contact, the ſmall one ſhall ſometimes have its repellency changed into attraction. Mr. Michell alſo infers from other experiments, that the attraction and repulſion of *magnets* decreaſe, as the ſquares of the diſtances from the reſpective poles increaſe. The differences of opinion in this reſpect are aſcribed by him, to the want of making proper allowances for that property of *magnets*, in conſequence of which they attract or repel equally at equal diſtances, together with the increaſe and diminution of power in the *magnets* with which the experiments were tried. See *Laws of* MAGNETISM.

5. If a *magnet* be cut through the axis, the parts or ſegments of the ſtone, which before were joined, will now avoid and fly each other. 6. If the *magnet* be cut by a ſection perpendicular to its axis, the two points, which before were conjoined, will become contrary poles; one in one, the other in the other ſegment. 7. Iron is not only attracted by a *magnet*, even more than another *magnet*, and equally attracts it, but alſo receives virtue from the *magnet* by application to it, or barely from an approach near it, though it do not touch it; and the iron receives this virtue variouſly, according to the parts of the ſtone it is made to touch, or even but to approach to. In order to communicate the magnetic virtue more effectually, the following methods are made uſe of: viz. it has been diſcovered, that iron rubbed upon one of the poles of the *magnet* acquires much greater virtue than from any other part of it, and this is more conſiderable from an armed *magnet*, than from a naked one. Farther, the more gently the iron is preſſed, and the more it is preſſed againſt the pole, the more magnetical it becomes. Again, it is more convenient to impregnate iron on one pole, than on both poles ſucceſſively; becauſe the iron receives magnetic virtue from each pole, in contrary directions, which deſtroy each other's effects. Moreover, the iron is much better impregnated by preſſing it uniformly and in the ſame direction, according to its length, than by rubbing it by the middle; and the extremity which touches the pole laſt, retains the greateſt virtue: it is alſo of importance, that the length of the iron be conſiderable. Beſides, a piece of poliſhed ſteel, or of pointed iron, receives more virtue than mere iron, or iron of the ſame figure: and, *cæteris paribus*, a piece of iron that is long, ſmall and pointed, is more ſtrongly impregnated than that of any other form. 8. If an oblong piece of iron be any way applied to the ſtone, it receives virtue from it, only as to its length. 9. The *magnet* loſes none of its own virtue by communicating any to the iron; though this is doubted by Mr. Savery; and this virtue it can communicate to the iron very ſpeedily; though the longer the iron touches or joins the ſtone, the longer will its communicated virtue remain in it; and a better *magnet* will communicate more of it, and ſooner, than one not ſo good. The late Dr. Gowin Knight practiſed a method, which he never publiſhed, of communicating to iron a very conſiderable magnetic virtue, and alſo of increaſing that of feeble *magnets*. From a report delivered to the Royal Society, in 1744, it appears that he had prepared a ſmall eight-cornered bar of ſteel, three inches, and almoſt ½ long, and about half an ounce Troy in weight, which liſted by one of its ends about eleven of the ſame ounces: that another plain bar of ſteel of a parallelopiped form, 5⅛ inches long, 1/10 inch broad, and 1/20 inch thick, weighing two ounces 8¾ penny-weights, liſted, in like manner, by one of its ends, twenty Troy ounces: that a ſteel bar, almoſt of the ſame form as the laſt, but only four inches in length, capped or armed with iron at each end, cramped with ſilver, and weighing all together, one ounce fourteen penny-weights, liſted by the feet of the armour full four pounds Troy; and that a ſingle block of ſteel, of a parallelopiped form, almoſt four inches long, 1 2/10 high, and 4/10 inch thick, armed with iron, cramped with braſs, and ſuſpended by a ring of the ſame, and weighing all together fourteen ounces one penny-weight, liſted by the feet of the armour, fourteen pounds 2¼ ounces, Troy weight. He alſo exhibited a compound artificial *magnet*, conſiſting of twelve bars of ſteel armed, which liſted by the feet of the armour as the laſt, twenty three Troy pounds 2½ ounces. At the ſame time he preſented before the ſociety, a ſmall armed loadſtone, which, with its armour, weighed ſeven penny-weights fourteen grains, and which could ſcarce lift two ounces; but improved by his method, it ſuſtained ſix ounces eighteen penny-weights and three grains. See *Armed* MAGNET, and *Artificial* MAGNET.

10. Iron will receive magneſiſm more eaſily than ſteel; the ſoft ſteel receives it much more eaſily than the ſpring-tempered, and the ſpring-tempered much more eaſily than

the hard: but a piece of ſpring-tempered ſteel will not return near ſo much magnetiſm, and is therefore incapable of being excited to the ſame degree as hard ſteel; ſoft ſteel will retain it ſtill leſs; and iron, which is the ſofteſt of all, ſcarce retains any. Mr. Michell has evinced the truth of theſe obſervations both by reaſoning and experiment. There are other bodies, beſides iron and ſteel, which are ſuſceptible of magnetiſm; theſe are probably no other than iron in ſome ſhape or other, or bodies that have a mixture of them: ſuch are all ſorts of iron ore after ignition, and ſome before. It is obſervable, that ſeveral of the hard ores of iron, which are not affected in the leaſt by the *magnet* in their natural ſtate, are vigorouſly attracted by it, when moderately roaſted; that the calces of iron, by ſlight roaſting with inflammable additions, are made to obey the *loadſtone*, and revived into their metallic form, each particle appearing now to be perfect iron; whilſt the calces of other metals are in no degree revived, without being brought into fuſion. There are alſo ſeveral ſorts of *heavy*, ſhining, opake, black, or dark chocolate-coloured ſand, moſt of which, if not all, are iron ores, which are ſuſceptible of magnetiſm. Of this kind is the dark-*brown* ſand or EMERY: we may alſo refer to this claſs moſt braſs, and ſeveral other metals; and bricks that have been much burnt in the fire. The magnetiſm of theſe is probably owing to a ſmall quantity of iron mixed with them. What is in the braſs, Mr. Michell conjectures, may come from the lapis calaminaris, which is ſaid to have often a ſmall mixture of iron in it: but Mr. Anderſon, who has ſucceeded in giving magnetiſm and polarity to braſs, has doubts as to the mixture of iron with braſs; particularly, becauſe braſs fuzes with a much leſs degree of heat than iron, and iron naturally ſwims in fluid braſs. Phil. Tranſ. vol. l. p. 774.

11. A needle touched by a *magnet* will turn its ends the ſame way towards the poles of the world, as the *magnet* itſelf does. 12. Neither *loadſtone* nor needles touched by it do conform their poles exactly to thoſe of the world, but have uſually ſome variation from them: and this VARIATION is different in divers places, and at divers times in the ſame place. 13. A *loadſtone* will take up much more iron when armed or capped, than it can when naked. And though an iron ring or key be ſuſpended by the *loadſtone*, yet the *magnetical* particles do not hinder that ring or key from turning round any way, either to the right or left. See ARMS and *Armed* MAGNET.

14. The force of a *loadſtone* may be variouſly increaſed or leſſened by the various application of iron, or another *loadſtone*, to it. 15. A ſtrong *magnet*, at the leaſt diſtance from a leſſer, or a weaker, cannot draw to it a piece of iron adhering actually to ſuch leſſer or weaker ſtone; but if it come to touch it, it can draw it from the other: but a weaker *magnet*, or even a little piece of iron, can draw away or ſeparate a piece of iron contiguous to a greater or ſtronger *loadſtone*. 16. In theſe northern parts of the world, the ſouth pole of a *loadſtone* will raiſe up more iron than the north pole. 17. A plate of iron only, but no other body interpoſed, can impede the operation of the *loadſtone*, either as to its attractive or directive quality. Mr. Boyle found this true in glaſſes ſealed hermetically; and glaſs is a body as impervious, as moſt are, to any effluvia. The magnetic virtue is ſenſibly continued through the ſubſtance of ſeveral contiguous bodies or pieces of iron, as keys, &c. it pervades the pores of the hardeſt bodies; and equally attracts the iron in vacuo, as in open air. 18. The power or virtue of a *loadſtone*, and of iron or ſteel impregnated with the magnetic virtue, may be impaired by long lying in a wrong poſition, by an electrical ſtroke as alſo by ruſt, wet, &c. and it may be quite deſtroyed by fire, and by LIGHTNING. 19. A piece of iron wire, well touched, will, upon being bent round in a ring, or coiled round on a ſtick, &c. generally, quite loſe its directive virtue: but it will always have it much diminiſhed: and yet if the whole length of the wire were not entirely bent, ſo that the ends of it, though but for the length of one-tenth of an inch, were laſt ſtrait, the virtue will not be deſtroyed in thoſe parts; though it will in all the reſt. This was firſt obſerved by Meſſ. Grimaldi, and de la Hire; and is confirmed by the experiments of Dr. Derham; who adds further, that though coiling or bending the wire as above, would always deſtroy its virtue by day, yet it would not do it in the evening. 20. The ſphere of the activity of *magnets* is greater and leſs at different times: in particular that referred to in the repoſitory of the Royal Society will keep a key or other body ſuſpended to another, ſometimes at the height of eight or ten feet; and at others, not above four feet. See 4. above. To which we may add, that the variation of the *magnetical* needle from the meridian varies at various times of the day; as appears from ſome experiments of Mr. Graham. See VARIATION.

21. By twiſting a piece of wire touched with a *magnet*, its virtue is exceedingly diminiſhed, and ſometimes ſo diſordered and confuſed, that in ſome parts it will attract, and in others repel; and even in ſome places, one ſide of the wire ſeems to be attracted, and the other ſide repelled, by one and the ſame pole of the ſtone. 22. A piece of wire that has been touched, being ſplit or cleft in two, the poles are ſometimes changed; as in a cleft *magnet*; the north becoming the ſouth, and the ſouth the north: and yet ſometimes one half of the wire will retain its former poles, and the other half will have them changed. To which it may be added, that laying one or other ſide of the half uppermoſt, cauſes a great alteration in its tendency or averſion to the poles of the *magnet*. 23. A wire being touched from end to end with the ſame pole of the *magnet*, the end wherein you begin will always turn contrary to the pole which touched it: if it be again touched the ſame way with the other pole of the *magnet*, it will then be turned the contrary way. 24. If a piece of wire be touched in the middle with only one pole of the *magnet*, without moving it backwards or forwards; in that place will be the pole of the wire, and the two ends will be the other pole. 25. If a *magnet* be heated red-hot, and again cooled either with its ſouth pole towards the north in a horizontal poſition, or with its ſouth pole downwards in a perpendicular poſition, its poles will be changed. 26. Mr. Boyle (to whom we are indebted for the following *magnetical* phænomena) found he could preſently change the poles of a ſmall fragment of a *loadſtone*, by applying them to the oppoſite extremes ones of a large *magnet*. Dr. Knight diſcovered a method of changing the direction of the poles in natural *magnets*, multiplying and variouſly placing them at pleaſure. In the firſt inſtance, recorded in the Philoſophical Tranſactions, he inverted the poles of a *magnet* by a proceſs, which required only a minute's time; ſo that the ſame end, which before attracted the ſouth end of the needle, now attracted the north and repelled the ſouth, and *vice verſâ*: in the ſame time he again turned the direction of the polarity of the ſtone at right angles, to its former direction; and afterwards inverted this laſt direction of the poles. In the ſecond ſeries of experiments, he cut a piece of natural *loadſtone* into the ſhape of a parallelopiped, $1\frac{1}{2}$ inch long, $\frac{7}{10}$ inch broad, and $\frac{3}{4}$ in thickneſs: its weight was three drams and ten grains. In this ſtone he placed the magnetical virtue in ſuch a manner, that the two oppoſite ends became, both of them, ſouth poles, and the middle was quite round a north pole. The two oppoſite ends of another ſtone were made both north poles, and the two oppoſite ſides ſouth poles. At one end of another ſtone, he placed a north pole ſurrounded by a ſouth; and at the other end a ſouth ſurrounded by a north pole; ſo that the edges of each ſurface had a pole of a different denomination from that which occupied the middle. On another occaſion, he inverted the poles at the ends of a piece of *magnet*, and then tranſferred them to the ſides of the ſtone. All theſe changes of the poles are eaſily produced by ſteel bars A B, C D, *Tab. Magneti/m*, *fig.* 3. impregnated with a ſtrong magnetic virtue, by which the piece of *magnet* EF, placed between them is ſo affected, that the poles may be changed at pleaſure, and excited in places that are touched by the ends of the bars. Mr. Michell has ſhewn the method of doing this both in ſmall and large *magnets*. If a ſmall and ſhort *magnet* is to have its poles changed, lay the ſupporters deſcribed under *Armed* MAGNET; ſo, that the centre of their force ſhall, at each end, lie at the end of the line deſigned to be the axis of the *magnet*, and touch it double in the manner explained under *Artificial* MAGNET, as near as may be in that direction. If the poles are to be converted, and the *magnet* be long enough, touch it double according to the directions for converting the poles of an artificial *magnet*; then ſupport it, and touch it over again with freſh touches: or if the *magnet* is ſhort, apply bars as ſupporters only, and change them two or three times: or elſe make uſe of the following method, applicable to large *magnets*. If the poles of ſuch are to be changed, the middle of the end of the piece of iron placed at each end of the *magnet*, (ſee *Armed* MAGNET) is to be placed againſt the end of the line deſigned to be the axis. If the poles are to be converted, it ſhould be done firſt by touching double, if a ſufficient force of magnetical bars can be applied for this purpoſe: but if by touching double, the poles will not be converted, place the *magnet* between two pieces of iron, then keeping them ſteady at their diſtance, remove the *magnet*, and connecting the pieces of iron by wedges of iron, that may not ſtand in the way of it, when it is to be put in its place again, apply the ſupporters as before, and putting the *magnet* in its place, take off the iron wedges. This may be done two or three times, if it be found neceſſary, retouching the ſupporters every time. See *Artificial* MAGNET. It is well known, that LIGHTNING not only deſtroys, but reverſes in ſome caſes, the poles of

magnetic needles. 27. Hard iron tools well tempered, when heated by a brisk attrition, as filing, turning, &c. will, while warm, attract thin filings or chips of iron, steel, &c. though not when cold; though there are not wanting some instances of their retaining the virtue when quite cold. 28. The iron bars of windows, &c. which have a long time stood in an erect position, grow permanently *magnetical*; the lower end of such bars being the north pole, and the upper end the southern. 29. A bar of iron that has not stood long in an erect posture, if it be only held perpendicular, will become *magnetical*, and its lower end the north pole; as appears from its attracting the south pole of a needle: but then this virtue is transient, and, by inverting the bar, the poles will shift their places. In order therefore to render the quality permanent in an iron bar, it muſt continue a long time in a proper position. But the fire will produce the effect in a ſhort time: for as it will immediately deprive a *loadſtone* of its attractive virtue, ſo it ſoon gives a verticity to a bar of iron, if, being heated red-hot, it be cooled in an erect poſture, or directly north and ſouth. Nay, tongs and pokers, by being often heated and ſet to cool again in a poſture nearly erect, have frequently gained this *magnetical* property. The *magnetic* virtue may be excited in iron and ſteel by electricity and lightning. 30. Mr. Boyle found, that by heating a piece of Engliſh oker red-hot, and placing it to cool in a proper poſture, it manifeſtly acquired a *magnetic* virtue. And an excellent *magnet* of the ſame ingenious gentleman's having lain near a year in an inconvenient poſture, had its virtue ſurpriſingly impaired; as if it had been injured by fire. 31. A needle well touched, it is well known, will point north and ſouth: if it have one contrary touch of the ſame ſtone, it will be deprived of its faculty; and by another ſuch touch it will have its poles quite changed. 32. If a bar of iron have gained a verticity by being heated red-hot, and cooled again, north and ſouth, and then hammered at the two ends; its virtue will be deſtroyed by two or three ſmart blows on the middle. Mr. Martin ſays, that by a ſmart ſtroke of a hammer on the untouched end of the dipping-needle, he has often cauſed the whole *magnetic* virtue to come to that end from the other, ſo as to make it dip on that ſide as much as it did on the other before: on the contrary, by ſuch a ſtroke he has ſometimes made it dip much more on the touched end than before. Sometimes, by ſtriking it, the needle, which dipped before, will be reſtored to its equilibrium, as if the virtue had made its eſcape, or were uniformly diffuſed all over the needle. 33. By drawing the back of a knife, or long piece of ſteel wire, &c. leiſurely over the pole of a *loadſtone*, carrying the motion from the middle of the ſtone to the pole; the knife or wire will accordingly attract one end of a needle: but if the knife or wire be paſſed from the ſaid pole to the middle of the ſtone, it will repel that end of the needle which in the other caſe it attracts. 34. Either a *magnet* or a piece of iron being laid on a piece of cork, ſo as to ſwim freely in water; it will be found, that whichſoever of the two is held in the hand, the other will be drawn to it: ſo that iron attracts the *magnet* as much as it is attracted by it; action and reaction being always equal. In this experiment, if the *magnet* be ſet aſloat, it will direct its two poles to the poles of the world. 35. A knife, &c. touched with a *magnet*, acquires a greater or leſs degree of virtue, according to the part it is touched on. It receives the ſtrongeſt touch, when it is drawn leiſurely from the handle towards the point over one of the poles: and if the ſame knife thus touched, and thus in poſſeſſion of a ſtrong attractive power, be retouched in a contrary direction, viz. by drawing it from the point towards the handle over the ſame pole, it immediately loſes all its virtue. Laſtly, It is obſerved by ſome writers, that the power or force of *magnets* is generally greater in ſmall than in large ones, in proportion to their bulk. It is very rare that very large ones will take up more than three or four times their own weight, but a ſmall one, that is only tolerably good, will take up eight, ten, or twelve times its weight. Mr. Martin mentions one, whoſe weight with the armature is only forty three grains, that will take up twenty-four times its own weight, or one thouſand and thirty-two grains; and another wore in a ring, weighing ſcarce three grains, that will take up ſeven hundred and forty-ſix grains, or two hundred and fifty times its own weight.

MAGNET, in *Medicine*. Some writers of the middle ages have, from a miſtaken tranſlation of Theophraſtus, been induced to account the *loadſtone* poiſonous, which the ancients were ſo far from doing, that they gave it inwardly. Galen aſcribes a purgative quality to it, and recommends it in droppes; and Dioſcorides preſcribes it as a good medicine to evacuate groſs melancholic humours. It is doubtleſs poſſeſſed of the ſame virtues with the other ores of iron, though of late never uſed inwardly, being only made an ingredient in ſome plaſters.

It has been ſaid, that the application of the artificial *magnet*, or of a *magnetical-bar* to the teeth, will effectually cure the tooth-ache.

MAGNET, in *Metallurgy* and *Chemiſtry*. Iron ores may generally be diſcovered to be ſuch by the *magnet*; for almoſt all of them will be attracted by it either before or after ignition. A ſtrong *artificial* MAGNET, well hung, and uſed as a needle, will beſt ſerve for this purpoſe. It will alſo readily find, and ſeparate any little bits of iron or ſteel from other things, and particularly iron or ſteel from thoſe of other metals. It will likewiſe diſcover whether tools, &c. are made of ſteel, or whether they are iron caſe-hardened; for the ſteel will receive a ſtrong touch, when the other will hardly receive any. For the uſe of the *magnetic* needle, in *Mining*, ſee NEEDLE. According to Neumann, the *magnet* is almoſt totally ſoluble in ſpirit of nitre, and partially in the vitriolic and marine acids.

MAGNET, *armed*, denotes one that is capped, caſed, or ſet in iron or ſteel, in order to make it take up a greater weight, and alſo more readily to diſtinguiſh its poles. For the method of arming the natural *magnet*, ſee ARM. Mr. Michell directs to increaſe the power of a natural *magnet*, if it be ſmall and ſhort, by laying a great number of iron bars at its ends, after the manner of ſupporters, care being taken to apply the proper poles; if it be pretty long, ſo as to allow room for it, by touching it alſo double with ſeveral bars, according to its bulk, applying them to all ſides at once. To increaſe the power of a large *magnet*, inſtead of placing ſupporters, he adviſes to put a large piece of iron, of the thickneſs and breadth of the *magnet* at each end of it. This piece of iron ſhould be either three or four times as long as it is thick, or elſe ſhort, and three or four times as large at the end not touching the *magnet*, as at the other: in the former of theſe ways, there are to be placed on one ſide, in the other caſe at the broad end, as many ſupporters as can conveniently ſtand there. This, if the *magnet* be very ſhort, may be ſufficient; if it be long, it ſhould be ſides be touched double. If the *magnets* to be thus improved be very ſuſceptible of magnetiſm, they ſhould have much thicker armour than is generally uſed, becauſe they will thus retain more magnetiſm; and the armour ſhould be ſo faſtened, that the hoops, &c. uſed for that purpoſe may not ſtand in the way of applying any thing to the ends, or the ſides; for it is much the beſt way to make any ſhort *magnets* magnetical in their armour, becauſe they will retain more power by this means. But Mr. Michell apprehends, that the beſt way of managing very large *magnets*, would be to fit them, in a direction parallel to the axis, into ſeveral long bars of the length of the ſtone, and having made them magnetical ſingly, to put them into their armour, in the manner directed for compound artificial *magnets*. The ſteel bars uſed for artificial magnets, may be armed and made magnetical, like the natural *magnets*. Armed compound artificial *magnets* may be made of ſeveral bars exactly of a length, with armour nicely fitted to them. The bars ſhould have the ſame proportions as thoſe of ſingle unarmed *magnets*; they ſhould be touched ſingly, and put into their armour, as they are touched, with the poles of the ſame denomination the ſame way. The armour ſhould be pretty thick, and ſhould have a wedge of iron applied to it, whilſt the bars are putting in, and till the whole is bound together and finiſhed; for which reaſon the caſe, that keeps the armour together at bottom, ſhould be put on before any of the bars are put in. The iron wedge ſhould always continue applied to the *magnet*, but when it is uſed; for this will be a great preſervation to it; though with all this precaution, it will loſe a great deal of its firſt ſtrength, in a very little time. Mr. Michell directs an occaſional *magnet* of this kind to be made in the following manner: let there be a ſmall box, about an inch deep, ſix inches long, and three or four wide; in the bottom of this box fix two bars of iron, at each end one, about $\frac{1}{2}$ inch ſquare, reaching quite acroſs the ends and through holes in one ſide, and projecting a little way beyond; theſe projecting ends ſerve as feet to lift with like thoſe of the common armed natural *magnet*: the faces of theſe feet ſhould lie in the ſame plane with each other, and they may be reduced, by taking off the edges, to about half the breadth of the bar, in the flat way of the box. When the *magnet* is wanted, apply a wedge of iron to the two feet, that come through the ſide of the box; and having made any number of the ſix-inch bars as magnetical as may be, place them one by one with their edges againſt the two iron bars in the box, and with their poles of the ſame denomination the ſame way, puſhing them cloſe againſt the ſide of the box, which will keep them from turning over and lying flat-ways. Having placed as

many of the six-inch bars as are required, in this manner, lay two or three doubles of flannel, or something else that is soft and spungy, over them, and press them against the two iron bars with the lid of the box, and fasten it down. Such a *magnet* as this may be easily taken to pieces and retouched, and set together again, as occasion shall serve. A *magnet* of this kind, consisting of three dozen of six inch bars, will lift fifty pound avoirdupois.

MAGNET, *arsenical*, in *Chemistry*, MAGNES *arsenicalis*, denotes a mixture of equal parts of arsenic, sulphur, and antimony, melted together over the fire, and condensed in manner of a stone.

It is a very gentle caustic, and was first invented by Angelus Sala. It succeeds very well in taking down fungous flesh in wounds. It has its name *magnet*, because, being worn during malignant diseases, it is supposed to preserve the wearer from infection, by a *magnetical* power.

MAGNET, *artificial*, is a steel or iron bar, impregnated with the magnetic virtue, so as to possess all the properties, and be used instead of the natural *loadstone*. The method of making *magnets* of this kind, by means of a natural *magnet*, and even without the assistance of any *magnet*, was suggested many years ago by Mr. Servington Savery, and particularly described in the Phil. Transf. N° 414. See also Abridgement, vol. vi. part ii. p. 260, &c. But as his method was tedious and operose, though capable of communicating a very considerable virtue, it was little practised. Dr. Gowin Knight was the first who brought this kind of *magnets* to their present state of perfection, so as to be of much greater efficacy than the natural ones. The result of his method, though the process itself was kept secret, was first published in the Phil. Transf. for 1744, vol xliii. art. 8. and Phil. Transf. for 1745, art. 3. See also vol. xliv. for 1747. art. 2. Mr. Wilson has lately communicated to the public Dr. Knight's method; who informs us, that having provided himself with a large quantity of clean filings of iron, he put them into a large tub, that was more than one-third filled with clean water: he then, with great labour, worked the tub to and fro for many hours together, that the friction between the grains of iron by this treatment, might break off such smaller parts as would remain suspended in the water for some time. The obtaining of these very small particles in sufficient quantity, seemed to him, to be one of the principal desiderata in the experiment. The water being thus rendered very muddy, he poured the same into a clean earthen vessel, leaving the filings behind; and when the water had stood long enough to become clear, he poured it out carefully, without disturbing such of the iron sediment as still remained, which now appeared reduced almost to impalpable powder. This powder was afterwards removed, into another vessel, in order to dry it: and this process was several times repeated. When a sufficient quantity of this fine powder was procured, he made a paste of it with linseed oil; preferring this vehicle, because it contained a considerable quantity of the phlogistic principle. With these two ingredients he made a stiff paste, which he well kneaded, before he formed it into convenient shapes, and then put upon wood, and sometimes on tiles, in order to bake or dry it before a moderate fire, at about a foot distance from it. In about five or six hours it generally attained a sufficient degree of hardness. When these baked pieces were become cold, he gave them their magnetic virtue in any direction he pleased, by placing them between the extreme ends of his large magazine of artificial *magnets* for a few seconds or more, as he saw occasion. By this method, the virtue they acquired was such, that when any one of those pieces was held between two of his bett ten-guinea bars, with its poles purposely inverted, it immediately of itself turned about to recover its natural direction, which the force of those very powerful bars was not sufficient to counteract. Phil. Transf. vol. lxix. part. i. for 1779. art. 5. However, the method of making artificial *magnets* was discovered and published by Mr. John Michell, in a Treatise of Artificial *Magnets*, printed in 1750, and by Mr. John Canton, in the Phil. Transf. for 1751, vol. xlvii. art. 6. p. 31. The process for this purpose was also found out by others, particularly by Marsil Ultgeleeze Natuurkund. Verhandl. tom. ii. p. 261. and Du Hamel, Hist. Acad. Roy. 1745 and 1750.

Mr. Michell's method of making *magnets* is as follows: prepare a dozen bars of steel, of about 1¼ ounce weight each, six inches long, and half an inch broad: let these be hardened with a full, but not too great heat: let one end be nicked all round with a chissel, to distinguish it from the other; and the ends of the bars should be cleaned after hardening, either upon a smooth stone, or razor-grinder's wheel: the size and shape of the bars may be varied at pleasure, provided that the length be proportioned to the thickness. The best sort of steel is that which has no veins of iron in it, and Mr. Michell has found the common blistered steel at least equal to any other. When any *magnet* does not answer expectation, it will be proper to harden it over again, with a greater or less degree of heat, till it proves better. In order to preserve these bars, contrive a box, that shall have two pieces of iron, about an inch long each, fixed upright in the middle of each end, over against each other, at the distance of six inches from outside to outside. These pieces of iron may be about ¾ inch square, and should be filed pretty smooth on the sides. Against these are to be placed, with their edges towards them, the twelve magnetical bars, six on one side, with their south, or north poles one way, and six on the other side with the same poles the contrary way. It is necessary to observe that these bars must neither be taken out, nor put in, all, or too many on a side at once; for if two only be left, with their poles of the same denomination the same way, without one or more on the other side to counterbalance their effects, they will damage each other: and if two of the same side be taken out together, or laid with their poles of the same denomination together, after they are taken out, they will also damage one another: and if this be the case, it will be proper to restore them, before they are used, after the manner prescribed for making of *magnets*. In order to make the marked ends of these bars south poles, and the other ends north poles, place six of them in a line north and south, bringing the unmarked end of one, to touch the marked end of the next throughout; the marked ends lying towards the north, which will be some advantage to them. Then take an armed *magnet*, and placing it with both poles upon one of the bars, the north pole towards the marked end, which is to be a south pole, and the south pole towards the unmarked end, which is to be a north pole, slide it backwards and forwards, from end to end of the whole line of bars three or four times, taking care that they all touch. Then taking it off, remove the two endmost bars into the middle, and pass over them again three or four times. Having thus touched the bars, it will not be improper to turn them with the other side uppermost, and to touch them over again on that side as before, omitting the endmost bars, till they are removed into the middle, where they also are to be touched.

If an unarmed *magnet*, either natural or artificial be used, lay the bars in a line as before; place the south pole of the *magnet* upon the marked end of the endmost bar, and slide it over the whole line to the end; then taking that pole off, place the north pole upon the same bar in its room, not at the extremity of the bar, but towards the middle, and slide it back again; then, change the poles again, observing to set the *magnet* on at the middle of the bar, and slide it to the other end, as at first. Having done this four or five times, remove the two endmost bars into the middle, and placing the south pole of the *magnet* upon the marked end of them, slide it to the unmarked end; and then, placing the north pole upon the unmarked end, slide it to the marked end. Let this be repeated three or four times; and turning the bars with the other side upwards, repeat the same process again. When the *magnets* are weak, it may be necessary to touch the bars, according to the preceding directions, before they are hardened, when they will receive the magnetic virtue more easily; then, making the whole dozen magnetical, in the manner hereafter prescribed, till they are as strongly so as they will be in their soft state, harden one half; and having made these again magnetical with the remaining half that are soft, harden those also, and proceed. But if the *magnets* are too weak to perform properly, even in this case, recourse must be had to smaller bars of steel, which should also be soft; and if these fail, bars of iron must be used. Having communicated a small degree of magnetism to six of the bars, let the other six, which are unmagnetical, be laid in a line, in the same manner as the former: and let AB *Tab. Magnetism, fig.* 4. represent this line, consisting of six bars, though three only are delineated. The line drawn across at the end of each bar, represents the mark distinguishing that end which is to be made the south pole, from the other. Let CD, EF represent the six bars already made magnetical: these lean against each other at the top, and are separated by a piece of wood, or other matter except iron, about a tenth of an inch at the bottom. The three *magnets* in CD, have all their south poles downwards, and are placed towards the unmarked ends of the bars in the line, which are to be north poles; and the three *magnets* in EF, have all their north poles downward, and are placed towards the marked ends of the bars, which are to be south poles. Slide these six magnetical bars, thus placed, backward and forward three or four times, over the whole length of the line. Then taking them off, having first brought them to touch at the

bottom, remove the two endmoſt bars of the line into the middle, and replacing the magnetical bars upon them, as before, paſs over thoſe again. Then taking them off, and turning the bars in the line with the other ſide upward, go over them again in the ſame manner, excepting the endmoſt bars; which, when thoſe in the middle are touched, are to be removed thither, to be touched in their turn. Thus the bars in the line will give a ſtronger power to that of the other ſix, by which they were touched: and, therefore, theſe latter may now be laid down in a line, and retouched, after the ſame manner, with the latter; when this is done, lay thoſe down again, and retouch them with the others: repeat this operation a few times, firſt touching one ſet, and then the other, till they have acquired as much magneticiſm as they will retain; or till they will receive no additional force, by any farther repetition. The ſix-inch bars, made magnetical after this manner, when properly hardened, will ſingly lift by one pole, a piece of iron, weighing a pound or better, if it be of a proper form; and ſix ſuch bars will touch a line of freſh bars of the ſame ſize, to their full perfection, by three or four times ſliding over them; except the endmoſt which muſt always be removed into the middle. As ſeveral *magnets* laid together with their poles of the ſame denomination the ſame way, will greatly injure one another, unleſs they have ſomething to counteract them, it is abſolutely neceſſary, not to place two of them, of a ſide, on together; but ſingly, one on one ſide, and one on the other, making them to lean together, that they may reſt againſt one another at the top: at the bottom they are preſerved from injuring one another, by being placed upon the bar which is to be made magnetical. In like manner, they muſt not be taken off two of a ſide together, but ſingly, firſt on one ſide, and then on the other. But the readieſt way of taking them off is firſt to bring them to touch one another at the bottom, in the ſame manner as they do at the top, and then they may be removed at once, and upon occaſion ſet on again; only obſerving not to ſeparate them again at the bottom, till they are placed upon the bar, which they are to touch. The reaſon of removing the two bars at the ends of the line, in order to their receiving a greater virtue, ſeems to be, that the ſix *magnets*, employed in touching, are endeavouring to make that part of the bar which is not included between them magnetical, in a contrary direction from that which is included between them. As this laſt is the direction of magneticiſm deſigned, the former endeavour would be injurious; and it is prevented by two cauſes: one of which is the power, whereby the ſteel reſiſts in a degree every endeavour, either to make it magnetical, or to deſtroy its magneticiſm; and the other is the power of the bars already in ſome meaſure magnetical, which lie at both ends of the bar that is touched. Now this laſt power is wanting at one extremity of thoſe bars, that are placed at the ends; and conſequently not having a ſufficient force fully to reſiſt the contrary endeavour of the *magnets* employed in touching them, they become leſs magnetical than the others, which have a ſufficient force. Though in the line of bars, when making magnetical, each bar has only one at each end to ſupport it (thoſe *magnets* that are placed at the ends of the others to preſerve them being called *ſupporters*) againſt the contrary endeavour of the ſix, made uſe of to touch it; and this does very well: yet ſome will receive an additional force by being ſupported with larger *magnets*; or inſtead of theſe, two or three of their own ſize, at each end: thoſe at the marked end all with their north poles touching it, and thoſe at the unmarked end all with their ſouth poles touching it. And becauſe there will be two or three north poles, and as many ſouth poles together amongſt the ſupporters, at the other end from the bar to be touched, that have nothing to counteract them, it will be proper to place the ſouth pole of another *magnet* amongſt the north poles, and the north pole of another amongſt the ſouth poles, that they may not hurt one another, which they otherwiſe will do.

The manner above deſcribed is called the *double touch*: and Mr. Michell obſerves, that two *magnets* will give more ſtrength to a bar of their own ſize, when uſed after this manner, than a ſingle *magnet* equal to five of the former in ſtrength, when applied after the manner of the ſingle touch. This ingenious writer has deſcribed a frame, contrived for holding ſeveral of the ſix-inch bars, when they are uſed in touching large bars, and when they cannot be conveniently held in the hand; for an account of which we muſt refer to his excellent pamphlet, already cited, p. 45, &c. ed. 2.

He obſerves, that the form of *magnets* is of very little conſequence, with regard to their receiving the magnetic virtue, provided that they have a ſufficient length in proportion to their bulk. The ſtrait bars may be made ſquare, round, or flat; though the flat are moſt convenient for touching, and probably ſomewhat ſtronger. Theſe may alſo be pointed at the ends, as in *fig.* 5. in order to render them lighter and to increaſe their power of lifting; though pointed bars are not ſo proper for touching. The *magnet* may be made in the form of a horſe-ſhoe, as in *fig.* 6. where a wedge of iron is ſuppoſed to be applied to the poles of it; and it will thus lie in a mariner's compaſs, a wedge of iron may be applied to its two poles, and it will lift by both poles at once. The *magnet* may be alſo made annular, which is a plain flat bar, bent flatways inſtead of edgeways; and a ſemicircular *magnet* may be bent flatways like the annular, or edgeways like the horſe-ſhoe; and two *magnets* of this kind may be conveniently placed together, in order to preſerve each other.

The poles of a *magnet* may be converted by placing the bars which are to retouch it, with their north poles towards its north pole, and the ſouth poles towards its ſouth pole. In doing this, they ſhould be placed on at the middle, and ſlid once or twice backwards and forwards, before it is ſupported; and then, that which was the north pole muſt be ſupported as a ſouth pole, by north poles; and that, which was the ſouth pole, as a north pole, by ſouth poles. In order to make a bar magnetical, ſo that it ſhall have ſeveral poles, ſupport it at the places where the poles are deſigned to be, with poles of a contrary denomination from thoſe deſigned; and if any place is ſupported with ſouth poles, the next places on either ſide muſt be ſupported with north poles, and *vice verſa*. Having done this, conſider each piece included between any two ſets of ſupporters, as a ſeparate bar, to be made magnetical, with its ſouth pole towards the north ſet of ſupporters, and its north pole towards the ſouth ſet, and touch it accordingly. *Magnets* of this ſort will not do well, unleſs they are very long; and at beſt they are always weak, and will very ſoon be injured; ſo that they ſhould only be made occaſionally.

Mr. Michell has alſo publiſhed a method of obtaining magneticiſm by means of three iron bars, without the aſſiſtance of a natural loadſtone, for which we ſhall refer to his pamphlet, p. 60, &c. and proceed to deſcribe the method deſcribed by the ingenious Mr. Canton, the remembrance of whoſe knowlege and communicative diſpoſition has led the editor often to lament his death in the courſe of this work; and whoſe friendſhip demands this tribute of reſpect. This gentleman has ſucceeded ſo well in his attempts to convey a conſiderable magnetic virtue to bars of hardened ſteel, as to be able to impregnate ſuch bars with this virtue to as high a degree, at leaſt, as any bars of the ſame weight and dimenſions, which he had ſeen or heard of; and to as high a degree, as he apprehends, the ſame bars, in their preſent ſtate, are capable of being impregnated. Mr. Canton was able, in about half an hour's time, to communicate to ſix bars of hardened ſteel, at firſt entirely deſtitute of any magnetic virtue, the utmoſt virtue they were capable of receiving; and that without the mediation or aſſiſtance of any natural *loadſtone*, or of any artificial *magnet*. Mr. Canton has publiſhed the deſcription of his proceſs with ſuch directions, that any perſon may readily perform the ſame. For this purpoſe procure a dozen bars; ſix of ſoft ſteel, each three inches long, $\frac{1}{4}$ inch broad, and $\frac{1}{8}$ inch thick, with two pieces of iron, each half the length of one of the bars, but of the ſame breadth and thickneſs; and ſix of hard ſteel, each $5\frac{1}{2}$ inches long, half an inch broad, and $\frac{1}{8}$ of an inch thick, with two pieces of iron of half the length, but the whole breadth and thickneſs of one of the hard bars: and let all the bars be marked with a line quite round them at one end. Then take an iron poker and tongs, (or two bars of iron) *Tab. Magnetiſm. fig.* 7. the larger they are, and the longer they have been uſed, the better: and fixing the poker upright between the knees, hold to it near the top one of the ſoft bars, having its marked end downward, by a piece of ſewing ſilk, which muſt be pulled tight with the left hand, that the bar may not ſlide; then graſping the tongs with the right hand a little below the middle, and holding them nearly in a vertical poſition, let the bar be ſtroked by the lower end, from the bottom to the top, about ten times on each ſide, which will give it a magnetic power ſufficient to lift a ſmall key at the marked end; which end, if the bar was ſuſpended on a point, would turn towards the north, and is, therefore, called the north pole, and the unmarked end is, for the ſame reaſon, called the ſouth pole of the bar. Four of the ſoft bars being impregnated after this manner, lay the other two, *fig.* 8. parallel to each other, at the diſtance of about one-fourth of an inch, between the two pieces of iron belonging to them, with a north and a ſouth pole againſt each piece of iron; then take two of the four bars already made magnetical, and place them together, ſo as to make a double bar in thickneſs, the north pole of one being

being even with the south pole of the other; and the remaining two being put to these, one on each side, so as to have two north and two south poles together, separate the north from the south poles at one end by a large pin, and place them perpendicularly with that end downward, on the middle of one of the parallel bars, the two north poles towards its south, and the two south poles towards its north end: slide them backward and forward three or four times over the whole length of the bar, and removing them from the middle of this, place them on the middle of the other bar as before directed, and go over that in the same manner: then turn both the bars with the other side upward, and repeat the former operation: this being done, take the two from between the pieces of iron, and placing the two outermost of the touching bars in their room, let the other two be the outermost of the four to touch those with; and this process being repeated till each pair of bars has been touched three or four times over, which will give them a considerable magnetic power, put the half dozen together after the manner of the four, *fig.* 9. and touch with them two pair of the hard bars, placed between the irons at the distance of about half an inch from each other; then lay the soft bars aside; and with the four hard ones set the other two be impregnated, *fig.* 10. holding the touching bars apart at the lower end near two tenths of an inch, to which distance let them be separated after they are set on the parallel bar, and brought together again after they are taken off; this being observed, proceed according to the method already described, till each pair has been touched two or three times over. But as this vertical way of touching a bar will not give it quite so much of the magnetic virtue as it will receive, let each pair be now touched once or twice over, in their parallel position between the irons, *fig.* 11. with two of the bars held horizontally, or nearly so, by drawing at the same time the north of one from the middle over the south end, and the south of the other from the middle over the north end of a parallel bar: then bringing them to the middle again without touching the parallel bar, give three or four of these horizontal strokes to each side. The horizontal touch, after the vertical, will make the bars as strong as they can possibly be made; as appears by their not receiving any additional strength, when the vertical touch is given by a greater number of bars, and the horizontal by those of a superior magnetic power. This whole process may be gone through in about half an hour, and each of the larger bars, if well hardened, may be made to lift twenty-eight Troy ounces, and sometimes more. And when these bars are thus impregnated, they will give to a hard bar of the same size its full virtue in less than two minutes; and will, therefore, answer all the purposes of magnetism in navigation and experimental philosophy, much better than the *loadstone*, which is well known not to have sufficient power to impregnate hard bars. The half dozen being put into a case, *fig.* 12. in such a manner as that two poles of the same denomination may not be together, and their irons with them as one bar, they will retain the virtue they have received; but if their power should, by making experiments, be ever so far impaired, it may be restored without any foreign assistance in a few minutes. And if, out of curiosity, a much larger set of bars should be required, these will communicate to them a sufficient power to proceed with, and they may in a short time, by the same method, be brought to their full strength. Mr. Canton, by the same process, communicated magnetic virtue to two larger bars, each half an inch square, 10¼ inches in length, and weighing nearly ten ounces and twelve penny-weights, to such a degree, that one of them lifted, by one of its ends, seventy-nine ounces and nine penny-weights; and a flat semicircular steel *magnet*, weighing an ounce and thirteen penny-weights, was made to lift, by applying its two ends together to an iron wedge, ninety Troy ounces. The same ingenious gentleman could also readily deprive his bars of their virtue; and charge the poles of a natural loadstone, by placing it in an inverted direction, between the contrary poles of his larger bars, laid down at some distance from each other, in the same strait line continued at the distance of about a quarter of an inch from either of the poles, without touching the stone with either of the bars.

The method in which the steel be made use of was hardened is as follows: having cut a sufficient quantity of the leather of old shoes into very small pieces, an iron-pan is provided, which a little exceeds the length of a bar, is wide enough to admit of two bars side by side without touching each other on the pan, and at least an inch deep. This pan is nearly half-filled with the bits of leather, upon which are laid the two bars, having fastened to the end of each a small wire for taking them out: the pan is then quite filled with the leather, and placed on a gentle flat fire, being covered and surrounded with charcoal. The pan being brought to somewhat more than a red heat, is kept for about half an hour, and the bars are suddenly quenched in a large quantity of cold water. Mr. Horne, in his Essays on Iron and Steel, p. 147. claims the merit of directing this process for hardening Mr. Canton's bars. Artificial *magnets* are preferable to the natural ones in a variety of respects. Mr. Michell mentions particularly, that they may be had at much less expence and trouble, and in greater plenty; that they are much superior to natural *magnets* in strength, and better able to communicate the magnetic virtue in proportion to their strength; that they are more easily restored to their former strength when they are at any time damaged; that they furnish several poles; and that they may be had in every form.

MAGNETICAL *amplitude* and *azimuth*. See AMPLITUDE and AZIMUTH.

MAGNETICAL *line*, is that line in which a needle would place itself, if left at entire liberty to turn itself as well vertically, as horizontally.

MAGNETICAL *meridian*, in *Navigation*. See MERIDIAN.

MAGNETICAL *needle*, in *Navigation*, &c. See NEEDLE.

MAGNETIS *lapis*, in the *Natural History of the Ancients*, the name given in different ages to two very different substances. The earliest Greek authors expressed by it the loadstone, which became afterwards called *Heraclius lapis*; and then the word *magnes* was applied to a very different stone brought from the same place, the neighbourhood of Magnesia in Lydia.

This was a fine beautiful and bright substance, of a pure white, and so very bright and glossy, as to bear a resemblance to polished silver. It was dug in large masses, and was of a texture capable of being wrought into any figure. Accordingly it was in great esteem among the ancients, who had it wrought into vessels for the use of the table.

It seems to be wholly unknown at present among the nations we have commerce with. Hill's Theophrast. p. 79.

MAGNETISM, MAGNETISMUS, that quality or constitution of a body, and its pores, whereby it is rendered *magnetical*, or a *magnet*.

Magnetism is found to be a transient power, capable of being produced and destroyed again.

MAGNETISM, *the laws of*, are laid down by Mr. Whiston in the following propositions.—1. The *loadstone* has both an attractive and a directive power united together: whereas iron touched by it has only the former; i. e. the *magnet* not only attracts needles, or filings of steel, but directs them to certain different angles, with respect to its own surface and axis: whereas iron, touched with it, does little or nothing more than attract them; still suffering them to lie along or stand perpendicular to its surface and edges in all places; without any such special direction.

2. Neither the strongest nor the largest *magnets* give a better directive touch to needles, than those of a less size or virtue: to which it may be added, that whereas there are two qualities in all *magnets*, an attractive and a directive one; neither of them depend one or are any argument of the strength of the other.

3. The attractive power of *magnets*, and of iron, will greatly increase or diminish the weight of needles on the balance; nay, it will overcome that weight, and sustain other additional weights too: while the directive power has a much smaller effect. Gassendus, indeed, as well as Mersennus and Dr. Gilbert, maintain, it has none at all: but by mistake; for Mr. Whiston found, from repeated trials on large needles, that after the touch they weighed less than before. One of 4584 grains, lost 24 grains by the touch; and another of 63776 grains weight, no less than 74 grains.

4. It is probable, that iron consists almost wholly of the attractive particles; and the *magnet* of the attractive and directive together; mixed, probably, with other heterogeneous matter; as having never been purged by the fire, which iron has: and hence may arise the reason why iron, after it has been touched, will lift up much greater weights than the *loadstone* that touched it.

5. The quantity and direction of *magnetic* powers, communicated to needles, is not properly, after such communication, owing to the *magnet* which gave the touch; but to the goodness of the steel that receives it, and to the strength and position of the terrestrial *loadstone*, whose influence alone those needles are afterwards subject to, and directed by: so that all such needles, if good, move with the same strength, and point to the same angle; what *loadstone* soever (provided it be good) they have been excited by. Nor does the touch seem to do much more in *magnetical*, than attrition does in electrical cases; i. e. it serves to rub off some obstructing particles, that adhere to the surface of the steel, and open the pores of the body touched, and so make way for the entrance and exit of such effluvia as occasion or assist the powers we are

speaking of. Hence Mr. Whiston takes occasion to observe, that the directive power of the *loadstone* seems to be mechanical; and to be derived from *magnetic* effluvia, circulating continually round it.

6. The absolute attractive power of different armed *loadstones* is, *cæteris paribus*, according to the quantity, not of their diameters or solidities, but of the surfaces of the *loadstones*; or in a duplicate proportion of their diameters.

7. The power of good *magnets* unarmed, not sensibly different in strength, similar in figure and position, but unequal in magnitude, is sometimes a little greater, sometimes a little less, than in the proportion of their similar diameters.

8. The *loadstone* attracts needles that have been touched, and others that have not been touched, with equal force, at distances unequal; viz. where the distances are to one another as 5 to 2.

9. Both poles of a *loadstone* equally attract needles, till they be, though roughly, touched; then it is, and then only, that one pole begins to attract one end, and repel the other: though the repelling pole will still attract upon contact, nay, at very small distances, notwithstanding.

10. The attractive power of *loadstones*, in their similar position to, but different distances from, *magnetic* needles, is in the sesquiduplicate proportion of the distances of their surfaces from their needles reciprocally; or as the mean proportionals between the squares and the cubes of those distances reciprocally; or as the square roots of the fifth powers of those distances reciprocally. Thus the *magnetic* power of attraction, at twice the distance from the surface of the *loadstone*, is between a fifth and sixth part of that power at the first distance; at thrice the distance, the power is between the fifteenth and fifteenth part; at four times the distance, the power is thirty-two times as small; and at six times the distance, eighty-eight times as small. Where it is to be noted, that the distances are not taken, as in the laws of gravity, from the centre; but from the surface: all experience assuring us, that the *magnetic* power resides chiefly, if not wholly, in the surfaces of the *loadstones* and iron; without any particular relation to any centre at all. The proportion here laid down was determined by Mr. Whiston, from a great number of experiments of Mr. Hawksbee, Dr. Brook Taylor, and himself. The force they measured by the chords of those arcs, by which the *magnet*, at several distances, draws the needle out of its natural direction, to which chords (as he has demonstrated) it is ever proportional. The numbers in some of their most accurate trials he gives us in the following table; setting down half the chords, or the sines of half those arcs of declination, as the true measures of the power of *magnetism*.

Distances in inches.	*Degrees of inclination.*	*Sines of ½ arcs.*	*Rat. sesquidupl.*
20	2	175	466
14½	4	349	216
13¾	6	523	170
12⅛	8	697	138
11½	10	871	105
10¼	12	1045	87
9½	14	1219	70

Sir Isaac Newton supposes magnetic attraction to decrease nearly in the triplicate ratio of the distance: Mr. Martin observes, that the power of his loadstone decreases in the sesquiplicate ratio of the distances inversely. Dr. Hellham found it to be as the squares of the distances inversely, which ratio agrees with that of the ingenious Mr. Michell: others as Dr. Brook Taylor, and Mr. Musschenbrock are of opinion, that this power follows no certain ratio at all, but that it is much quicker at greater distances than at small ones, and that it is different in different stones. See *Phenomena of the* MAGNET, N° 4.

11. An inclinatory, or dipping-needle, of six inches radius, and of a prismatic or cylindric figure, when it oscillates along the *magnetic* meridian, performs there every mean vibration in about 6′ or 360″; and every small oscillation in about 54″, or 330″; and the same kind of needle, four feet long, makes every mean oscillation in about 24′, and every small one in about 22″.

12. The entire power of *magnetism* in this country, as it affects needles a foot long, is to that of gravity nearly as 1 to 300; and as it affects needles four feet long, as 1 to 600.

13. The quantity of *magnetic* power accelerating the same dipping needle, as it oscillates in different vertical planes, is ever as the cosines of the angles made by those planes, and the *magnetic* meridian, taken on the horizon.

Thus if we would estimate the quantity of forces in the horizontal and vertical situations of needles at London; we shall find, that the latter, in needles a foot long, is, to the entire force along the *magnetic* meridian, as 96 to 1005; and in needles four feet long, as 9667 to 10000: whereas in the former, the entire force in needles a foot long, is as 28 to 1005; and in those four feet long, as 2569 to 10000.

Whence it follows, that the power by which horizontal needles are governed in these parts of the world, is but one quarter of the power by which the dipping needle is moved.

Hence, also, since the horizontal needle is moved only by a part of the power which moves the dipping-needle; and that it only points to a certain place in the horizon, because that place is the nearest its original tendency of any its situation will allow it to tend to; whenever the dipping-needle stands exactly perpendicular to the horizon, the horizontal needle will not respect one point of the compass more than another, but will wheel about every way unerringly.

14. The time of oscillation and vibration, both in dipping and horizontal needles equally good, is as their length directly; and the actual velocity of their points along their arcs is always equal.

Hence *magnetic* needles are, *cæteris paribus*, still better, the longer they are; and that in the same proportion with their length.

15. The earth on which we live, includes within it a vast spherical *magnet*, concentrical thereto, having its own poles, meridians, equator, and parallels; and all much of the same general nature with those of small *terrellæ*, or spherical *loadstones*, in the possession of the curious among us.

16. The power of a good *terrella*, or a spherical *loadstone*, as it affects a needle a foot long, is equal to the *magnetic* power of that internal *loadstone* about two and a half, or three diameters of such *loadstone*. From which consideration, the quantity of *magnetic* attraction, at all distances from the internal *loadstone*, for needles a foot long, may be determined; and from the same consideration it appears, that the diameter of this internal *loadstone* is about eleven hundred and fifty miles. To which we add, that, in regard Sir Isaac Newton has demonstrated, that the power of gravity diminishes within the earth, and is less there than at its surface, nearly in the proportion of its greater nearness to the centre, the *magnetic* power, at two thousand nine hundred miles distance from us, and nearly one thousand and sixty from the earth's centre, which is ⅛ of the power of gravity here, will be somewhat greater than the power of gravity there: which limit is worthy our attention, gravity being stronger than *magnetism* on the one side of it, and weaker on the other; we mean, as it affects needles of one foot diameter. At that limit, therefore, at least near the *magnetic* poles, iron a foot long will be twice as heavy, and fall twice as fast, as any other natural body, viz. by the union of those two equal powers, gravity and *magnetism*; and of consequence, above that limit, such an iron will be less than twice as heavy, below it more than twice as heavy, as any other natural body.

17. The earth's internal *loadstone* is not fixed to our upper parts, but is moveable with respect to them, and actually revolves on the earth's axis, from east to west, in a certain long period of time; as appears, beyond contradiction, from the constant variation of the horizontal needle westward, as well as the regular increase of inclination of the dipping needle.

The only way to render this motion, i. e. the variation, possible and intelligible (to use Dr. Halley's words), is to suppose it to turn about the centre of a globe, having its centre of gravity fixed and immoveable in the same common centre of the earth. This moveable internal surface must likewise be loose, and detached from the external parts of the globe, which may be reckoned the shell, and the other the nucleus, or inner globe, included within it, with a fluid medium between. Now, from the variation's moving westward, it is plain, that the forefaid nucleus has not precisely attained the same degree of velocity with the exterior parts in their diurnal revolution: but so nearly equals it, that in three hundred and sixty-five revolutions, the difference is scarce sensible; and must probably have arisen from hence, that the impulse, whereby the diurnal motion was impressed on the earth, was given to the external parts, and thence communicated to the internal.

18. This internal *magnet* has one central pole northward, in the nature of the poles of our common *loadstones*; but its southern pole appears not to be central, but rather circular, and that at a great distance from the southern pole of the earth.

19. The northern *magnetic* pole is now situate, says Mr. Whiston, about the latitude of 76 degrees ½; i. e. thirteen degrees ½ from the north pole of the earth, and about 30 degrees eastward from the meridian of London.

20. The southern *magnetic* circular pole has its centre, or central pole, nearly in the parallel of 60 degrees: and, in a meridian passing along the east coast of Borneo, about 117 degrees eastward of London. Its radius is also an arc of a great circle of about 44 degrees.

21. The respective motion of the internal *magnet*, or the velocity v.s. of its north pole, appears to be 27 deg. 0 min. 21. 144 years, *i. e.* upwards of one degree in five years; so that it makes an entire revolution in 1920 years.

Hence, as the number of degrees in the upper earth's diurnal revolution is to the number of days in the revolution of the internal *magnet*, *i. e.* as 1 is to 360000, so is the respective motion of this *magnet* from east to west, to the real motion of the upper earth from west to east; or, to speak strictly, so is the difference of their motions from west to east to the entire motion of the upper earth the same way. This external fixed earth has therefore communicated almost all its motion already to the internal *magnet*; and can communicate no more than this difference of their motion, and that only in an infinite term of years; or, in other words, this real internal motion can never be the seven hundred thousandth part swifter than it is apprehended. This internal motion, therefore, began with the commencement of the diurnal motion of the upper earth; and has gone on still faster and faster by the communication of that motion through the intermediate fluid. Since, therefore, action and re-action are equal, and tend to contrary parts, this internal *loadstone*, thus accelerated by the upper part, must have all along retarded that upper earth, and made the diurnal rotation still slower and slower. This acceleration on one side, and retardation on the other, must have been very great at the first beginning of the diurnal motion, when the difference of their motion was equal to the entire motion itself, and must have been diminishing ever since. To which cause is probably owing that acceleration of the moon's motion with respect to that of the earth, since the time of the old astronomers, first taken notice of by Dr. Halley, and embraced by Sir Isaac Newton. And the same consideration seems to suggest a method for determining the age of the world; for, were the proportions of the quantity of matter in the upper earth to the internal *magnet*, with the tenacity of the intermediate fluid, &c. known, one might go back from the known difference of their velocity now, and find those differences and quantities of motion themselves, *a priori*, in all past ages; or, were the velocity of the first diurnal rotation of the upper earth known, we might geometrically determine, *a priori*, how long ago that rotation began, or how ancient our earth is.

22. The variation of *magnetic* needles from the azimuth of the meridians of the internal *magnet* is derived from the difference of the strength of the several parts of the internal *magnet*'s surface; which as it is only to be known by experience, that variation cannot be determined beforehand, unless where there are good accounts how much it had formerly been; it being probable, that it returns round, and will be the same in any year of the next revolution of the internal *magnet*, that it has been in the like year of any former revolution, or will itself have a revolution in about 1920 years.

23. The two fixed *magnetic* poles in our upper earth first introduced by Dr. Halley, as necessary to solve the irregularity of the variation of the horizontal needle from the meridians of the moveable internal *magnet* seem not to have any just foundation in nature, the like irregularities being found in the common *terrestrial*, or spherical *loadstones*, and being both accounted for from the composition of the *magnet*, which are found to have parts of different degrees of purity, strength and perfection; so that where the parts are weaker than ordinary, the stronger neighbouring parts prevail, and draw the needle that way: not but Dr. Gilbert's notion of prominent and depressed parts on *magnets* may have some room, and be allowed to contribute somewhat to such variations. See VARIATION.

MAGNETISM, *on the cause of*, or the manner in which these phænomena of the *magnet* are produced, we have yet no hypothesis that will satisfactorily account for them. Plutarch tells us, the *magnet* attracts iron, by emitting some spherical effluvia, whereby the contiguous air being opened and driven on either side, does again drive that contiguous to it; and thus the action being communicated round, the iron is thereby protruded: but this is contradicted by the equally vigorous action of the *loadstone* in vacuo, and in the open air. Others of the ancients ascribe the action of the *magnet* to a soul that animates it; and others to an unknown sympathy between the effluvia of the iron and those of the *magnet*.

An opinion that has much prevailed among the moderns, is that of Descartes, maintained by Malebranche, Rohault, Regis, &c. and even admitted and confirmed by Mr. Boyle, &c. In this it is supposed, that there is continually flowing, from the poles of the world, a subtile, impalpable, and invisible matter, channelled or striated: which matter, circulating round the earth, in the planes of the meridians, re-enters at the pole, opposite to that from which it issued, and passes again through the poles parallel to its axis: that the *magnet* has two poles answerable to those of the earth; and that out of these there issues a matter like that just mentioned; and that this matter, entering at one of the poles, gives the impulse whereby iron tends to the *magnet*, and produces what we call *attraction*. Now, besides the *magnetical* matter re-entering the poles of the *magnet*, there is always a certain quantity thereof circulating round the *magnet*, composing a kind of vortex about it. The space wherein this matter moves, is the sphere of activity of the *magnet*, within which its attractive faculty is confined.

Dr. Gilbert, in his work De Magnete, folio, printed 1600, concludes, from some experiments which he made, that the needle is not attracted by the *magnet*, but turned into its position, by what he calls a disponent virtue; which he supposed to surround the stone, somewhat in form of an atmosphere.

As to its directive faculty, or the inclination of a needle touched with it to the poles of the world, and its dip to a point beneath the horizon, they follow from the same principle; since were the *magnet* or needle to have any other situation, the *magnetic* matter would strike on its other surfaces in vain; and, not being able to get admission, would, by degrees, change its situation, till such time as its pores corresponded to the course of the *magnetical* matter; which situation having once acquired, it would cease to move, the *magnetical* matter then ceasing to disturb it.

The form or essence of a *magnet* therefore is supposed to consist in its being perforated by an infinite number of parallel pores; some whereof are disposed to admit the striated matter from the north pole of the world, others that of the south: hence the north and south poles of the *magnet*.

Mr. Harsfocker maintains, that the *magnet* is no more than a common stone, full of an infinite number of hollow prisms; which, by the diurnal motion of the earth, are ranged parallel to each other, and nearly parallel to the axis of the earth. These prisms have their cavities filled with an extremely subtile matter, which, by the diurnal motion of the earth, is passed from prism to prism; thus making a circulation, and returning into the prisms where it first began. From these principles he deduces all the phænomena of the *magnet*; and M. Andry does the same, from the doctrine of alkali and acid.

For the directive power of the *magnet*, Mr. Whiston, from the first, second, third, &c. laws of *magnetism*, inclines to think it mechanical; and ascribes it to *magnetic* effluvia circulating continually round the *loadstone*; of which circulations, he thinks, there are evident indications in *magnetic* experiments; as Mr. Boyle thinks there are of the *magnetism*, or *magnetic* effluvia, of the earth; though these effluvia are never yet rendered sensible, as electric effluvia began to be in his time. But the attractive power Mr. Whiston thinks entirely unmechanical, as the power of gravity is; not being able to devise any such motion of a subtile fluid belonging to the *loadstone*, as will account for the attractive power in the reciprocal ratio proportion of the distances reciprocally; though if he could, yet would that be no more than to remove the immediate power of the Supreme Being one step farther; the last resort of all mechanical principles whatever being in the unmechanical power and efficacy of the Deity.

Dr Knight deduces from several experiments the following propositions, which he offers not so much to explain the nature of the cause of *magnetism*, as the manner in which it acts: the *magnetic* matter of a *loadstone*, he says, moves in a stream from one pole to the other internally; and is then carried back in a curve line externally, till it arrive again at the pole where it first entered, to be again admitted; the immediate cause why two or more *magnetical* bodies attract each other in the first degree and the same stream of *magnetical* matter thro' them: and the immediate cause of *magnetic* repulsion is the endless and accumulation of the *magnetic* matter. Phil. Trans. vol. xliv. p. 671. See Mr. Michel reflects the notion of a subtile fluid, but though he proposed to publish a theory of *magnetism* established by experiments, no such theory has appeared. Signior Beccaria, from observing that a sudden stroke of LIGHTNING gives polarity to *magnets*, conjectures, that a regular and constant circulation of the whole mass of the electric fluid from north to south may be the original cause of *magnetism* in general. This current he would not suppose to arise from one source, but from several, in the northern hemisphere of the earth: the aberration of the common centre of all the currents from the north point, may be the cause of the *variation* of the needle; the period of this declination of the centre of the currents may be the period of the variation; and the obliquity with which the currents strike into the earth may be the cause of the dipping of the needle, and also why bars of iron

more easily receive the *magnetic* virtue in one particular direction. Lettie dell' Elettricismo p. 269. or Priestley's Hist. Elec. vol. i. p. 409, &c. For the principal properties, with respect to which *magnetism* and electricity differ from or resemble each other, see ELECTRICITY.

MAGNETISM is also used, by some *Chemists*, to signify a certain nature whereby one thing becomes affected at the same time with another, either in the same, or in a different manner. This amounts to the same with what they otherwise call SYMPATHY.

MAGNIFYING, among *Philosophers*, is chiefly used in speaking of microscopes, which are said to *magnify* objects, that is, to make them appear bigger than they really are, though, in reality, they do not, nor can, *magnify* any object, but only shew it nearer, and discover more of its parts, than before were taken notice of.

The *magnifying* power of denſe mediums of certain figures was known to the ancients, though they were far from underſtanding the cauſe of this effect. Seneca ſays, that ſmall and obſcure letters appear larger and brighter through a glaſs globe filled with water; and he abſurdly accounts for it by ſaying, that the eye ſlides in the water, and cannot lay hold of its object. Nat. Queſt. lib. i. c. 6.

Alexander Aphrodiſienſis, the great commentator upon Ariſtotle, who flouriſhed near two centuries after Seneca, ſays, that the reaſon why apples appear large when they are immerſed in water is, that the water which is contiguous to any body is affected with the ſame quality and colour; ſo that the eye is deceived in imagining the body affected to be larger. But the firſt diſtinct account we have of the *magnifying* power of glaſſes is in the writings of Alhazen, who flouriſhed in the twelfth century; and he was preceded by our own countryman Roger Bacon, who, in his Opus Majus, demonſtrates, that if a tranſparent body interpoſed between the eye and an object be convex towards the eye, the object will appear magnified; nor is it improbable that from the obſervations of Alhazen and Bacon the conſtruction of SPECTACLES was derived.

MAGNIFYING *glaſs*, in *Optics*, denotes a little ſpherical convex lens; which, in tranſmitting the rays of light, inflects them ſo, as that the parallel ones become converging, and thoſe which were diverging become parallel; by means whereof, objects viewed through them appear larger than when viewed by the naked eye. See MICROSCOPE.

MAGNISSA, in *Mineralogy*, a name given by ſome of the ancients to the white pyrites, called by others *lenadithes* and *oppobalſus*. See MARCASITE.

MAGNITUDE, any thing that has parts without (or *extra* to) parts connected together by ſome common term.

Magnitude is any thing locally extended, or continued; or that has ſeveral dimenſions.

The origin of all *magnitude* is a point, which, though void of parts itſelf, yet its flux forms a line, the flux of that a ſurface, and of that a body.

Magnitude amounts to much the ſame with what is otherwiſe called *quantity*.

MAGNITUDE *geometrical* may be uſefully conſidered as generated or produced by motion. Thus lines may be conceived as generated by the motion of points; ſurfaces, by the motion of lines; ſolids, by the motion of ſurfaces; angles may be ſuppoſed to be generated by the rotation of their ſides.

Geometrical magnitude is always underſtood to conſiſt of parts; and to have no parts, or to have no *magnitude*, are conſidered as equivalent in this ſcience. There is, however, no neceſſity for conſidering *magnitude* as made up of an infinite number of ſmall parts; it is ſufficient that no quantity can be ſuppoſed to be ſo ſmall, but it may be conceived to be farther diminiſhed: and it is obvious, that we are not to eſtimate the number of parts that may be conceived in a given *magnitude*, by thoſe which in particular determinate circumſtances may be actually perceived in it by ſenſe, ſince a greater number of parts become ſenſible, by varying the circumſtances in which it is perceived. See Mac-Laurin's Fluxions, art. 290, &c.

Many of late have ſuppoſed geometrical *magnitude* to be compoſed of infinitely ſmall parts, and infinite in number; and hence have raiſed many paradoxes and myſteries in a ſcience wherein there ought to be none. Nay, infinitely ſmall parts of infinitely ſmall parts, &c. *ad infinitum*, have been introduced without the leaſt neceſſity. See Mac-Laurin's Fluxions in the Introduction, where he makes ſeveral remarks on Monſieur de Fontenelle's *Geometrie de l'Infini*. See EXTENSION.

MAGNITUDE, *literal*, denotes a *magnitude* expreſſed by letters.

MAGNITUDE, *numerical*, is that expreſſed by numbers.

MAGNITUDE, *broken*, denotes a fraction.

MAGNITUDE, *complex*, is that formed by multiplication.

MAGNITUDE *incommenſurable* is that which has no proportion to unity.

MAGNITUDE *apparent* of a body, in *Optics*, is that meaſured by the optic or viſual angle, intercepted between rays drawn from its extremes to the centre of the pupil of the eye. It is one of the fundamental maxims in this ſcience, that whatever things are ſeen under the ſame or equal angles, appear equal; and *vice verſa*.

The *apparent magnitudes* of an object, at different diſtances are in a ratio leſs than that of their diſtances reciprocally.

The *apparent magnitudes* of the two great luminaries the ſun and moon, at riſing and ſetting, are a phenomenon that has extremely embarraſſed the modern philoſophers. According to the ordinary laws of viſion, they ſhould appear the leaſt when neareſt the horizon, as being then fartheſt diſtant from the eye; and yet we find the contrary to be true in fact.

Thus, it is well known, that the mean *apparent magnitude* of the moon is 30′ 20″, in round numbers 30′, at a full moon in the midſt of winter, and when ſhe is in the meridian, and at her greateſt northern latitude, and conſequently at her leaſt elevation above our horizon: it is alſo as well known, that when ſhe is in this ſituation, being looked upon by the naked eye, ſhe appears to be, accommodating her *magnitude* to our ſenſible meaſures, about a foot broad. But when ſhe is looked upon as ſhe riſes, ſhe appears to be three or four foot broad, and yet if we take her diameter with an inſtrument, both in the one ſituation and the other, we ſhall find that ſhe is only 30′.

Ptolemy, in his Almageſt, lib. i. cap. 3, has aſcribed this appearance to a refraction of the rays by vapours, which actually enlarge the angle under which the moon appears; juſt as the angle is enlarged by which an object is ſeen from under water: and his commentator Theon explains diſtinctly how the diſtortion of the angle in the object immerſed in water is cauſed. But it was afterwards diſcovered, that there is no alteration in the angle: upon which another ſolution was ſtarted by the Arab Alhazen; and followed and improved by Vitello, Kepler, Peckham, Rog. Bacon, and others. According to Alhazen, the ſight apprehends the ſurface of the heavens as flat, and judges of the ſtars as it would of ordinary viſible objects extended upon a wide plain; the eye ſees them under equal angles, but withal perceives a difference in their diſtances, and (on account of the ſemidiameter of the earth, which is interpoſed in one caſe, and not in the other) that it is hence induced to judge thoſe which appear more remote to be greater. Some farther improvement was made in this explanation by Mr. Hobbes, though he fell into ſome miſtakes in his application of geometry to this ſubject. For he obſerves, that this deception operates gradually from the zenith to the horizon; and that if the apparent arch of the ſky be divided into any number of equal parts, thoſe parts, in deſcending towards the horizon will gradually ſubtend a leſs and leſs angle; and he was the firſt who expreſly conſidered the exalted appearance of the ſky as a real portion of a circle. Deſcartes, and from him Dr. Wallis, and moſt other authors, account for the appearance of a different diſtance under the ſame angle, from the long ſeries of objects interpoſed between the eye and the extremity of the ſenſible horizon; which makes us imagine it more remote than when in the meridian, where the eye ſees nothing in the way between the object and itſelf. This idea of a great diſtance makes us imagine the luminary the bigger; for any object being ſeen under any certain angle, and believed at the ſame time, very remote, we naturally judge it muſt be very large, to appear under ſuch an angle, at ſuch a diſtance. And thus a pure judgment of the mind makes us ſee the ſun, or the moon, bigger in the horizon than in the meridian; notwithſtanding their images painted on the retina are really leſs in the former ſituation than the latter.

James Gregory Geom. Par. Univerſ. p. 141. ſubſcribes to this opinion: Father Malebranche alſo, in the firſt book of his Recherche de la Verité, printed in 1673. has explained this phenomenon almoſt in the expreſſion of Des Cartes: and Huygens, in his Treatiſe on the Parhelia, tranſlated by Dr. Smith, Optics, art. 436, has approved, and very clearly illuſtrated the received opinion. The cauſe of this fallacy, ſays he, in ſhort, is this; that we think the ſun or any thing elſe in the heavens, to be remoter from us, when it is near the horizon, than when it approaches towards the vertex, becauſe we imagine every thing in the air that appears near the vertex to be no farther from us than the clouds that fly over our heads;

heads; whereas, on the other hand, we are uſed to obſerve a large extent of land lying between us and the objects near the horizon, at the far end of which the convexity of the ſky begins to appear; which, therefore, with the objects that appear in it, is uſually imagined to be much farther from us. Now when two objects of equal magnitudes appear under the ſame angle, we always judge that object to be larger which we think is remoter. And this is the true cauſe of the deception we have been ſpeaking of. It is a wonder that an hypotheſis ſo rational as this ſhould ever loſe its credit, after having been maintained by writers of reputation, and for a great number of years. But it was generally imagined, that the actual perception of thoſe objects which divide the ſpace that is intercepted betwixt the eye and the horizon was neceſſary, in order to its ſuggeſting the idea of its extraordinary diſtance: and thus philoſophers were led to form much more objectionable ſolutions of the phenomenon. Accordingly Gaſſendus was of opinion, that the pupil of the eye, which is always more open as the place is more dark; being more ſo in the morning and evening than at other times, by reaſon the earth is covered with groſs vapours; and beſides, being obliged to paſs through a longer column or ſeries of vapours to reach the horizon; the image of the luminary enters the eye at a greater angle, and is really painted there larger at the former times than the latter. In anſwer to which, it may be ſaid, that, notwithſtanding this dilatation of the pupil, occaſioned by the obſcurity, if the moon be viewed through a little pin-hole made in a paper, ſhe appears leſs when in the horizon, than in the meridian. Nor can any thing be more abſurd, than the poſition of Gaſſendus, who aſſerts, that a dilated pupil magnifies an object for the ſame reaſon as a convex glaſs does.

F. Gouye advances another hypotheſis, which is, that when the luminaries are in the horizon, the neighbourhood of the earth, and the groſs vapours wherewith they then appear enveloped, have the ſame effect with regard to us, as a wall, or other denſe body, placed behind a column; which, in that caſe, appears bigger than when inſulate, and encompaſſed on all ſides with an illumined air. Farther, it is obſerved, that a column, when fluted, appears bigger than before, when it was plain; the flutes being ſo many particular objects, which, by their multitude, occaſion the mind to imagine the whole object, whereof they are compoſed, of a larger extent. The ſame thing may be ſaid of the ſeveral objects ſeen towards the horizon, to which the ſun or moon correſpond at their riſing and ſetting. And hence it is, that they appear larger ſtill, when they riſe or ſet between trees; the narrow, yet diſtinct, intervals whereof have the ſame effect with regard to the apparent diameter of the luminary, as a greater number of flutes with regard to the ſhaft of a column.

Biſhop Berkeley ſuppoſed, that the moon appears larger near the horizon, becauſe her appearance is then fainter, and her beams affect the eye leſs; but this hypotheſis is refuted by Dr. Smith. Mr. Robins has recited ſome other opinions on this ſubject, Math. Tracts, vol. ii. p. 242. The commonly received opinion has been diſputed not only by F. Gouye, who obſerves, Acad. Par. 1700, p. 11, that the horizontal moon appears equally large acroſs the ſea, where there are no objects to produce the effect aſcribed to them; but alſo by Mr. Molyneux, who ſays, Phil. Tranſ. abr. vol. i. p. 221. that if this hypotheſis be true, we may at any time increaſe the apparent magnitude of the moon, even in the meridian; for, in order to divide the ſpace between it and the eye, we need only to look at it behind a cluſter of chimnies, the ridge of a hill, or the top of a houſe. He alſo makes the ſame obſervation with F. Gouye, above mentioned, and farther obſerves, that when the height of all the intermediate objects is cut off, by looking through a tube, the imagination is not helped, the moon being ſtill conceived to be as large as before. However, Mr. Molyneux advances no hypotheſis of his own. Dr. Deſaguliers has well illuſtrated the doctrine of the horizontal moon, Phil. Tranſ. abr. vol. viii. p. 130, upon the ſuppoſition of our imagining the viſible heavens to be only a ſmall portion of a ſpherical ſurface, and conſequently ſuppoſing the moon to be farther from us in the horizon than near the zenith, and by ſeveral ingenious contrivances he demonſtrated how liable we are to ſuch deceptions. But the moſt complete illuſtration of this curious ſubject is given us by Dr. Smith. The concavity of the heavens, he ſays, appears to the eye, which is the only judge of an apparent figure, to be a leſs portion of a ſpherical ſurface than a hemiſphere. In other words, the centre of the concavity is much below the eye, and by taking a medium among ſeveral obſervations, he found that the apparent diſtance of its parts at the horizon was generally between three or four times greater than the apparent diſtance of its parts over head. This he determined by meaſuring the actual height of ſome of the heavenly bodies, when, to his eye, they ſeemed to be half way between the horizon and the zenith. In this caſe their real altitude was only twenty-three degrees. When the ſun was but 30° high, the upper arch always appeared leſs than the under, and he thought that it was always greater when the ſun was about 18° or 20° high. Mr. Robins, in his Tracts, vol. ii. p. 245, ſhews how to determine the apparent concavity of the ſky in a more accurate and geometrical manner; by which it appears, that if the altitude of any of the heavenly bodies be 20° at the time when it ſeems to be half way between the horizon and the zenith, the horizontal diſtance will be hardly leſs than four times the perpendicular diſtance; but if that altitude be 28°, it will be little more than two and a half. Dr. Smith, having determined the apparent figure of the ſky, is able to give a ſatisfactory explanation of the phenomenon of the horizontal moon, and other ſimilar appearances in the heavens. For ſuppoſing the arc A B C, *Tab. III. Optics fig.* 43, to repreſent that apparent concavity, he found that the diameter of the ſun and moon would ſeem to be greater in the horizon that at any propoſed altitude, meaſured by the angle A O B, in the proportion of its apparent diſtances O A, O B. The numbers that expreſs theſe proportions he reduced into the following table, anſwering to the correſponding altitudes of the ſun or moon, which are alſo exactly repreſented to the eye in the figure, in which the moon, placed in the quadrantal arc F G deſcribed about the center O, are all equal to each other, and repreſent the body of the moon in the heights there noted, and the unequal moons in the concavity A B C are terminated by the viſual rays that come from the circumference of the real moon, at O. Thoſe diameters of theſe unequal moons at A and B do, therefore, bear the ſame proportion to each other, as their apparent diſtances O A, O B; and they muſt appear in the ſame proportion that they really have in this concave, becauſe we judge all objects in the heavens to be in this ſurface: ſo that the appearance to the eye is exactly the ſame, as if ſeveral moons were painted upon a real ſurface A B C in the proportions here aſſigned; in which caſe we ſhould certainly judge the real magnitudes of the larger paintings of the lower moon to be really larger, though the viſible *magnitudes* of them all, anſwering to their equal images upon the retina, were exactly equal. For the ſame reaſon Dr. Smith obſerves, that all the objects and diſtances of ſtars in the heavens, as well as the ſun and moon, muſt ſeem to be greater in the horizon than in higher ſituations; which is known to be the caſe. He alſo obſerves, that the apparent concave of the ſky being leſs than an hemiſphere is the cauſe that the breadths of the colours in the inward and outward rainbows, and the interval between the bows appear leaſt at the top, and greater at the bottom; and by an eſtimate of the apparent breadths of the inward rainbow, at two different heights, made by a friend, he determined the apparent concavity of the ſky to be much the ſame as by the former methods. See HALO. This theory of the horizontal moon is alſo confirmed by the appearances of the tails of comets, which, whatever be their real figure, *magnitude*, and ſituation in abſolute ſpace, do always appear to be an arc of the concave ſky; and in farther confirmation of it, he gives us Mr. Cotes's explanation of the optical appearance of a remarkable meteor, ſeen in the year 1716. Beſides the general cauſe above ſtated of the appearance of the horizontal moon, Dr. Smith acknowledges, that, at different times, the moon appears of different magnitudes even in the ſame horizon, and occaſionally of an extraordinary large ſize. This, he is inclined to believe is chiefly owing to an extraordinary largeneſs of her picture upon the retina, which, in the preceding general theory, was ſuppoſed to be invariable. This, he ſays, might beſt be examined by taking the diameter of the moon with a micrometer, or by noting the year and day of the month, together with the heights of the barometer and thermometer. For if it ſhould appear, by many ſuch obſervations, that the largeſt horizontal moons generally happen at her perigee, in the warmeſt ſummer evenings, the barometer being low, and the thermometer high; ſince theſe cauſes are independent of one another, and all conſpire to enlarge the picture of the moon, we may reaſonably conclude that theſe extraordinary moons are chiefly owing to the concurrence

of these circumstances. But since the difference in the apparent magnitude of the moon is not increased $\frac{1}{30}$th part of the whole in consequence of her being in her perigee, and the enlargement of the image in all the other cases here mentioned is very inconsiderable, it is probable that when the moon is imagined to be so much larger than usual, the imagination is farther imposed upon by some circumstances, which have not been attended to. Smith's Optics, vol. i. p. 63, &c. Remarks, p. 53.

MAGNOLIA, in *Botany*. See *Laurel-leaved* TULIP-*tree*.

MAGNUM *os carpi*. This is the third bone of the second row in the carpus, and is the largest of all the bones of that part. It is of a considerable length, and has a kind of articular round head, which is received into the cotyloide cavity formed by the two first bones of the first row; and this articulation is capable of a small degree of flexion and extension. The digital side is a cartilaginous basis unequally and obliquely triangular, the apex being turned inward. It is articulated with the second metacarpal bone, and is also a little notched on the radial edge for its articulation with the small edge of the metacarpal bone. The radial side is very small, and near the basis, being articulated with the os pyramidale; the rest of this surface is without cartilage; the cubital side is double, answering to a like side in the os uniforme with which it is articulated. The outer surface, which forms a part of the outer surface of the carpus, is broad, rough, and uneven, for the insertion of ligaments: the inner surface is likewise rough, but narrower, and round both surfaces are several depressions, which, while the bone is in the body, are filled with small glands, ligaments, &c. Winslow's Anatomy, p. 83.

MAGODUS, among the Romans, a name given to those players who sometimes acted the part of men, and sometimes of women: the word is derived from μαγος, *magus*, and ωδη, *ode*, properly denotes those players who performed extraordinary feats and gestures.

MAGOPHONIA, formed from μαγος, *magus*, and φονος, *slaughter*, the name of a feast among the ancient Persians, held in memory of the expulsion of the Magians.

The Magus Smerdis having usurped the throne of Persia, upon the death of Cambyses, 521 years before Jesus Christ, seven of the principal lords of the court conspired to drive him out of it. Their design was executed with good success: Smerdis, and his brother, another Magus, called Patizithes, were killed. Upon which the people also rose, and put all the Magi to the sword; insomuch that there would not one have escaped, had not night come upon them. Darius, son of Hystaspes, was then elected king: and, in memory of this massacre of the Magi, a feast was instituted, says Herodotus, called *Magophonia*. See MAGI.

MAGPYE, in *Ornithology*, a well known species of the CORVUS, or the *corvus pica*, in the Linnean system. The colours of this bird are remarkable: its beak, white, green, and purple, and the rich and gilded combination of the glosses on the tail are at least equal to those that adorn the plumage of any other: it feeds on worms, insects, and small birds, and will destroy young chickens: it is a crafty, restless, noisy bird, called by Ovid *nemorum custodia picta*. This bird is easily tamed, and may be taught to imitate the human voice: its nest is entirely covered with thorns, except one small hole for admittance: it lays six or seven eggs, of a pale green colour spotted with brown. Pennant.

MAGRA, a word used by some writers for a sort of red earth, and by others for the cornelian, the red jasper, or any other stone of a red colour.

MAGUDARIS, a name by which Dioscorides calls the HIERBIUM.

MAGYDARIS, in *Botany*, a name used by Theophrastus, and other of the old authors, for the lasserpitium or LASERWORT.

MAHALEB, in the *Materia Medica*, the name of the fruit of a sort of wild CHERRY called *cerasus sylvestris amara*, or the wild bitter cherry, by Bauhine. The wood of the tree is of a greyish cast, and fine grain, with a mixture of red in the veins, and is very firm, and of a sweet smell, and used by the French in making cabinets; the leaves and flower carry a rude resemblance of those of the common cherry; the fruit is round, black, and resembles a cherry, having the same sort of stone in it, the kernel of which is like the bitter almond in taste. It is commended in external applications, and the perfumers of France use it in their washballs. It is to be chosen fresh and sweet, for it very often has an intolerable stinking smell, like that of bugs.

MAHERNIA, in *Botany*, a genus of the *pentandria polygynia* class: the characters of which are, that the calyx is dentated into five horizontal points, that it has five petals, and five heart-shaped nectaria, and the fruit is a capsule with five cells. There are two species.

MAHIE, the name given by the inhabitants of Otaheite, or George's island, to their BREAD-FRUIT when made into a kind of sour paste, which, in consequence of having undergone a fermentation, will keep a considerable time, and supply them with food when no ripe fruit is to be had. When therefore they see a great shew of new fruit on the trees, they strip them all at once of their former crop, of which they make *mahie*. This *fuccinneum* for ripe bread-fruit is thus made. They gather the fruit before it be perfectly ripe, and laying it in heaps cover it closely with leaves. In this state it ferments, and becomes disagreeably sweet; the core is then taken out entire, and the rest of the fruit thrown into a hole in their houses, dug on purpose, and neatly lined in the bottom and sides with grass. The whole is then covered with leaves, and heavy stones are laid upon them. In this state it undergoes a second fermentation, and becomes sour, after which it will suffer no change for many months. It is taken out of this hole, as it is wanted for use, and being made into balls, it is wrapped up in leaves and baked, and thus dressed it will keep for five or six weeks. It is eaten, both cold and hot, and the natives of those countries seldom make a meal without it; but to captain Cook and his company the taste was as disagreeable, as that of a pickled olive generally is, the first time it is eaten. Hawkesworth's Account, &c. vol. ii. p. 143, 196.

MAHIM, MAHEM, MAIHEM, or MAYHEM, in *Law*, a *maim*, or corporal hurt, whereby a man loseth the use of any member, that is, or may be, of defence to him in battle; as the eye, hand, foot, scalp of the head, foretooth, or, as some say, a finger, or toe: but the cutting off his ear or nose are not held to be *mayhems* at common law, because they do not weaken but only disfigure him. The word comes from the French *mehain*, of *mehaigner*, *to mutilate*: the canonists call it *membri mutilatio*; and all agree, it consists in the loss of a member, or of the use thereof.

By the ancient law of England he that *maimed* any man was sentenced to lose the like part, which is still the law in Sweden: but this was disused, and *mayhem*, by the common law, was only punishable by fine and imprisonment; unless perhaps the offence of *mayhem* by castration, which all our old writers held to be felony. But by subsequent statutes the crime and punishment of *mayhem* were put more out of doubt. 5 Hen. IV. cap. 5. 37 Hen. VIII. cap. 6. and by 22 and 23 Car. II. cap. 1. called the Coventry Act, it is enacted, that if any one shall, of malice aforethought, or by lying in wait, cut or disable the tongue, put out an eye, slit the nose, cut off the nose or lip, or cut or disable any limb or member of another person, with intention in so doing to *maim* or disfigure him, it is felony without benefit of clergy; and, when the case is difficult to judge whether it be a *mayhem*, or not, the judges commonly view the party wounded, and sometimes take the opinion of the *surgeons*.

A person who *maims* himself, for the purpose of begging, and also a person who disables himself, that he may not be impressed for a soldier, may be indicted and fined. The offence of wilfully and maliciously shooting at any person, which may endanger either killing or *maiming* him, though no such evil consequence ensue, is made felony without benefit of clergy, by 9 Geo. I. cap. 22. Maliciously *maiming* of cattle in the night time incurs a forfeiture of treble damages, by action of trespass, or upon the case, 22 and 23 Car. II. c. 7.

MAYHEM, *appeal of*. See APPEAL.

MAHO *Tree*. See *Spinus* MALLOW.

MAHOGANY. See CEDAR.

MAHOMET *Pigeon*, the common English name of a species of pigeon, called by Moore the *columba Numidica alba*. It is of the same shape and size with the Barbary pigeon, and has all the characters of that species, but is always perfectly white, which gives the red circle about the eyes a more lively look.

MAHOMETANISM, MAHOMETISM, or MOHAMMEDISM; the system of religion broached by *Mahomet*, and still adhered to by his followers.

Mahomet was born at Meccain Arabia, in the year of Christ 571 or 572 according to the most probable opinion: in the thirty-eighth year of his age he began to withdraw himself into a solitary cave near Mecca, called the cave of Hira, for the purpose of forming his system of imposture; the propagation of which he commenced in the fortieth year of his age, when he assumed the title of the apostle of God: and having gained nine disciples, some of whom were the principal men of the city, in the forty-fourth year of his age he openly published his imposture to the people of

Mecca, and declared himself a prophet sent by God to recover them from Paganism, and to teach them the true religion. However, he was obliged to abandon Mecca, and to settle at Medina, on the 16th of July, A.D. 622, the year of the hegira or *Mahometan* epocha: here his party confiderably increased, and having made feveral fucceisful excurfions againit the Arab tribes, and conitrained them by force to embrace his religion, his fovereignty was eitablished in 628, and he united in himfelf the facred character of chief pontiff of his religion, as well as the royal; both which characters he tranfmitted to all his fucceffors, who, by the title of caliphs, reigned after him. But they were afterwards deprived of the regal authority, firit by the governors of the provinces, who, about the year of hegira 325, aflumed it to themfelves, and made themfelves kings in their refpective governments; and then by others who arofe on this diftraction of the empire to ufurp upon them, till at laft they had nothing left but the name and fhadow of what they had once been. In the year of Chriit 629 *Mahomet*, at the head of an army of ten thoufand men, reduced Mecca, and extended his conquefts, with his religion, through moft parts of Arabia: and the remaining Arabs fubmitted and embraced his impofture in 631. In the next year he died at Medina, being, according to fome hiitorians, fixty-three years of age. It has been faid by many, that *Mahomet*'s tomb, being of iron, under a vault of loadftones, hangs in the air, and that this paffes for a great miracle in the opinion of his followers. But this is a mere fable. Pliny informs us, lib. xxxiv. cap. 14, that Dinocrates the architect, had begun to roof the temple of Arfinoe at Alexandria with loadftone, that her image made of iron, might feem to hang there in the air; but the defign was interrupted by his own death, and that of Ptolemy, who had ordered it to be done in honour of his fifter.

Mahometanifm is embraced by the Turks, Perfians, and feveral nations among the Africans, and many among the Eaft Indians.

Brerewood fays, that if we divide the known countries of the earth into thirty equal parts, five of them are Chriftians, fix *Mahometan*, and nineteen Pagan.

The fyftem of *Mahometanifm* is contained in the Koran, commonly called the Alcoran.

The firft and chief article of the *Mahometan* creed is, that *there is no other god but one God*; which they have from the Koran, where thefe words are repeated inceffantly: *there is no other god but he. Your God is the only God. I am God, and there is no other God but I.* This grand axiom of their theology feems to have been taken from the Jews, who were continually rehearfing thofe words of Deuteronomy, *Hear, O Ifrael; the Lord our God is One.*

For this reafon, the *Mahometan* account all fuch as own any thing of number in the deunity, to be infidels or idolaters. And accordingly, one of the firft leffons they teach their children is, that God is neither male nor female, and confequently can have no children.

The fecond article of *Mahometanifm* conffits in this, *that Mahomet was fent from God.* By which they exclude all other religions; under pretence that their prophet was the laft and greateft of all the prophets that God would ever fend, and that as the Jewifh religion ceafed with the coming of the Meffiah, fo likewife the Chriftian religion was to be abrogated with the coming of *Mahomet.* Not but they own Mofes and Jefus Chriit to have been great prophets; but *Mahomet* they hold to be *The Prophet*, by way of excellence, commiffioned to purge the holy fcriptures of the Old and New Teftament, which they allow, from the corruption introduced in them by Jews and Chriftians, and to reftore the law of God to its original purity; and the paraclete or comforter promifed in the fcriptures.

The *Mahometans* call their religion *Islam*, denoting as fome fay, *refignation* or *fubmiffion* to the fervice and commands of God, but, according to others, formed from the root *falama*, fignifying *to be fawed*, and therefore the fame with *the religion* or *ftate of falvation*; and they divide it into two diftinct parts, *viz. iman*, i. e. *faith* or *theory*; and *din*, i. e. *religion* or *practice*: and teach, that it is built on five fundamental points, one belonging to faith, and the other four to practice.

Under the confeffion of faith already recited, they comprehend fix diftinct branches, viz. belief in God; in his angels; in his fcriptures; in his prophets; in the refurrection and day of judgment; and in God's abfolute decree and predeftination both of good and evil. The four points relating to practice, are prayer, under which are comprehended thofe waihings or purifications which are neceffary preparations required before prayer; alms; faiting; and the pilgrimage to Mecca. Their faith in God has been already mentioned: with refpect to the r

opinion of angels, they believe them to have pure and fubtil bodies, created of fire, and that they are differently employed, in writing down the actions of men, or in carrying the throne of God, and other fervices. The four angels whom they regard as moft diftinguifhed by God's favour, and on account of the offices affigned them, are Gabriel, Michael, Azrael the angel of death, who feparates men's fouls from their bodies, and Ifrafil, whofe office it will be to found the trumpet at the refurrection. They alfo believe that two guardian angels, changed every day, attend on every man, to obferve and write down his actions. Their whole doctrine concerning angels they have borrowed from the Jews, who learned the names and offices of thofe beings from the Perfians. The devil, called by *Mahomet Eblis* from his defpair, was one of thofe angels who are neareft to God's preference, called Azazil, and fell, according to the doctrine of the Koran, for refufing to pay homage to Adam at the command of God. They alfo admit an intermediate order of beings, called genii, fome of which are good and others bad.

As to the fcriptures, the *Mahometans* are taught by the Koran, that God, in divers ages of the world, gave revelations of his will in writing to feveral prophets, the whole, and every word of which, it is abfolutely neceffary for every good Moflem to believe. *Mahomet* acknowledges the divine authority of the Pentateuch, Pfalms, and Gofpel, and often appeals to the conformity of the Koran with thofe writings, and to the prophecies which he pretended were contained concerning himfelf, which the Jews and Chriftians have fuppreffed.

At death, they maintain, that the bodies of thofe who believe the unity of God, and the miffion of *Mahomet*, reft in peace, and are refrefhed with the air of paradife; otherwife they are grievoufly tormented. The fouls of the former are conveyed to heaven, where a place is affigned them according to their merit and degree; thofe of the wicked are tormented, till they are rejoined to their bodies at the refurrection; the approach of which will be known by certain figns that precede it: thefe are the leffer and the greater figns: the latter of which are the fun's rifing in the weft; the appearance of a monftrous beaft, which fhall rife out of the earth in the temple of Mecca; war with the Greeks and the taking of Conftantinople; the coming of Anti-chriit; the defcent of Jefus on earth; war with the Jews; the eruption of Gog and Magog; a fmoke which fhall fill the whole earth; an eclipfe of the moon; the return of the Arabs to the worfhip of their ancient idols; the difcovery of a vaft heap of gold and filver by the retreat of the Euphrates; the demolition of the temple of Mecca by the Ethiopians; the fpeaking of beafts and inanimate things; the breaking out of fire; the appearance of a man, who fhall drive men before him with his ftaff; the advent of the Mhodi, or director, a perfon of the family of *Mahomet*, to govern the Arabians, and fill the world with righteoufnefs; and a wind that fhall fweep away the fouls of all who have but a grain of faith in their hearts. But the immediate fign of the refurrection will be the firft blaft of the trumpet, which will be founded three times. The day of judgment will continue, as the Koran fays in one place, one thoufand years, but according to another paffage, fifty thoufand years: the refurrection, fay they, will be general, extended to all creatures, angels, genii, men, and animals; who will be aflembled on the earth, give an account of their actions, and receive retribution. On this occafion each perfon will have the book wherein all the actions of his life are written delivered to him, and their works will be weighed in a balance, which they minutely defcribe. When the examination is finifhed mutual retaliation will follow; which will be executed by taking away a proportionable part of the good works of him who offered injury to another, and adding it to him who fuffered it. Brutes will be changed into duft; and the believing genii be afligned a place near the confines of paradife, and the unbelieving punifhed eternally and caft into hell, with the infidels of mortal race. After this procefs, the good and wicked are conducted to a bridge, called ALSIRAT; over which the former fhall fafely pafs, while *Mahomet* and his Moflems lead the way, but the latter will fall down headlong into hell; where there are feven different apartments, adapted to as many diftinct claffes of the damned, who will fuffer both from intenfe heat and exceffive cold. In this ftate infidels only will be liable to eternal punifhment; but the Moflems, or believers will be delivered thence, after they have expiated their crimes by their fufferings. This place of punifhment is feparated from paradife by a wall, fo fmall in breadth as to admit the bleffed and damned to converfe together. The righteous, after having paffed the bridge above mentioned, will be refrefhed by drinking at the pond of their prophet, and then admitted into paradife, fituated

situated in the seventh heaven, and next to the throne of God; where they will feed on the most delicious fruits, be clothed in the most splendid silken garments, refreshed with rivers of water, wine, milk, and honey, and entertained with the most delightful music, and the ravishing girls of paradise with black eyes, the enjoyment of whose company will be a principal felicity of the faithful.

It appears from the Koran, that women as well as men will not only be punished for their evil actions, but also receive the reward of their good deeds, and that both will enjoy a perpetual youth.

Farther, the orthodox doctrine with respect to predestination is, that every thing which happens in this world proceeds entirely from the divine will, and is irrevocably fixed from all eternity in the preserved table; God having secretly predestinated not only the adverse and prosperous fortune of every person in this world, in the most minute particulars, but also his faith and infidelity, his obedience or disobedience, and consequently his everlasting happiness or misery after death; which fate or predestination it is not possible for any foresight or wisdom to avoid.

In regard to the four fundamental points of religious practice, *Mahomet* is said to have declared, that the practice of religion is founded on cleanliness, which is one half of the faith, and the key of prayer, without which it will not be heard by God. Such is the opinion which the *Mahometans* entertain of cleanliness, that it is purely on this account they seem to have adopted circumcision, though it be not mentioned in the Koran. *Mahomet* has obliged his followers to pray five times every twenty-four hours, at certain stated times, turning their faces towards the temple of Mecca, which is pointed to by a niche in their mosques: the life and spirit of prayer, they hold, is the inward disposing of the heart; nor do they ever perform this duty in sumptuous apparel, nor suffer their women to attend them on these occasions.

Alms, among the *Mahometans*, are legal and voluntary; the giving of which is frequently inculcated in the Koran. Fasting is called by *Mahomet*, the gate of religion; and his followers are expressly required to fast during the month of Ramadan; which they observe by abstaining from meat, drink, and women, from day-break till sunset. Besides this, they have several other voluntary fasts. The pilgrimage to Mecca is so necessary a point of practice, that, according to a tradition of *Mahomet*, he who dies without performing it may as well die a Jew or a Christian; and it is expressly commanded in the Koran. The various ceremonies prescribed to those who perform this pilgrimage are extremely absurd and ridiculous, and appear to be relicks of idolatrous superstition.

Besides the fundamental points of faith and practice above recited, the *Mahometans* are required by the Koran, to abstain from wine, gaming, usury, divining by arrows, the eating of blood and swine's flesh, and whatever dies of itself, or is slain in honour of any idol, or strangled, or killed by accident, or by any other beast. The Koran allows polygamy within certain limits; forbidding any man to have more than four, whether wives or concubines: but *Mahomet* had the privilege of marrying as many wives, and keeping as many concubines as he pleased. It allows also of divorce; but severely punishes fornication and adultery. The day of the week which *Mahomet* has set apart for public worship is Friday; besides which they have two annual feasts called BEIRAM.

After the death of *Mahomet*, a schism arose among his followers, which divided them into two great factions, whose separation not only gave rise to a variety of opinions and rites, but also excited the most implacable hatred, and the most deadly animosities. Of these factions, the one acknowledged Abubeker, the father-in-law of *Mahomet*, as his successor, or the true caliph, and its members were distinguished by the name of SONNITES; while the other adhered to Ali, his son-in-law, and were known by the title of SCHIITES. Both, however, adhered to the Koran as a divine law, and the rule of faith and manners; to which indeed the former added, by way of interpretation, the Sonna, i. e. a certain law, which they looked upon as descended from *Mahomet* by oral tradition, and which the Schiites refused to admit. Among the Sonnites we are to reckon the Turks, Tartars, Arabians, Africans, and the greatest part of the Indian *Mahometans*; whereas the Persians, and the subjects of the grand mogul are generally considered as the followers of Ali, though the latter indeed seem rather to observe a strict neutrality in this contest. Besides these two grand factions, there are other subordinate sects among the *Mahometans*, which dispute with warmth concerning several points of religion, though without violating the rules of mutual toleration. Of these sects there are four, which far surpass the rest in point of reputation and importance, viz. the Hanefites, the sect of Malec, the sect of Al Shafei, and that of Ebn Hanbal, which are called the orthodox *Mahometans*. Sale's Preliminary Discourse. See ALCORAN.

The rapid success, which attended the propagation of this new religion, was owing to causes that are plain and evident, and must remove, or rather prevent, our surprize, when they are attentively considered. The terror of *Mahomet*'s arms, and the repeated victories which were gained by him and his successors, were, no doubt, the irresistible arguments that persuaded such multitudes to embrace his religion, and submit to his dominion. Besides his law was artfully and marvellously adapted to the corrupt nature of man; and, in a more particular manner, to the manners and opinions of the eastern nations, and the vices to which they were naturally addicted: for the articles of faith which it proposed were few in number, and extremely simple; and the duties it required were neither many nor difficult, nor such as were incompatible with the empire of appetites and passions. It is to be observed farther, that the gross ignorance, under which the Arabians, Syrians, Persians, and the greatest part of the eastern nations, laboured at this time, rendered many an easy prey to the artifice and eloquence of this bold adventurer. To these causes of the progress of *Mahometanism*, we may add the bitter dissensions and cruel animosities that reigned among the Christian sects, particularly the Greeks, Nestorians, Eutychians, and Monophysites; dissensions that filled a great part of the East with carnage, assassinations, and such detestable enormities, as rendered the very name of Christianity odious to many. We might add here, that the Monophysites and Nestorians, full of resentment against the Greeks, from whom they had suffered the bitterest and most injurious treatment, assisted the Arabians in the conquest of several provinces, into which, of consequence, the religion of *Mahomet* was afterwards introduced. Other causes of the sudden progress of that religion will naturally occur to such as consider attentively its spirit and genius, and the state of the world at this time. Mosheim's Eccl. Hist. vol. ii. p. 9. ed. 8vo.

MAJA, in *Ornithology*, the name of a bird described by Nieremberg as very common in the island of Cuba, and frequenting the fields of rice in large flocks. It is described to be a small bird of a yellowish colour, very delicate, and well tasted, and remarkable for having a remarkable on the back or outside of the neck.

MAIAGUE, in *Ornithology*, the name of a Brasilian bird of the web-footed kind, but having its hinder toe loose. It is of the size of the common goose; its head is large and round; its neck long, and it always carries it crooked like a swan; its beak is strong and hooked at the end; it is all over of a brownish black in colour, except that its throat is yellow. It is found about the mouths of rivers, and feeds on fish; it builds on the ground; it is very nimble in running, flying, and diving, and is not easily taken, but is a very well tasted fowl.

MAIDEN, an edged instrument used in some countries, particularly Scotland, for the beheading of criminals.

The *maiden* is a broad piece of iron, of a foot square, sharp on the lower part, and loaded above with lead, so as scarce to be lifted: at the time of execution, it is pulled up to the top of a narrow wooden frame ten feet high, with a groove on each side for the *maiden* to slide in. The prisoner's neck being fastened to a bar underneath, on a sign given, the *maiden* is let loose, and the head in an instant separated from the body.

MAIDEN is also the name of a machine first used in Yorkshire, and since introduced into other places, for washing of linen; consisting of a tub nineteen inches high, and twenty-seven in diameter at the top, in which the linen is put, with hot water and soap, to which is adapted a cover, fitting it very closely, and fastened to the tub by two wedges; through a hole in the middle of the cover passes an upright piece of wood, kept at a proper height by a peg above, and furnished with two handles, by which it is turned backward and forward: to the lower end of this upright piece is fastened a round piece of wood, in which are fixed several pieces, like cogs of a wheel. The operation of this machine is to make the linen pass and repass quick through the water. Gent. Mag. vol. xxii. p. 32.

MAIDEN-*assizes*, are those where no person is condemned to die.

MAIDEN-*hair*, *adiantum*, in *Botany* and *Medicine*. See ADIANTUM.

MAIDEN-*hair*, *black*, a name sometimes given to the *dwarf-fern*. See MILTWASTE.

MAIDEN-*hair*, *Spanish*. See TRICHOMANES.

MAIDEN-*hair*, *white*. See *Wall*-RUE.

MAIDEN-*plum*. See *American* PLUM.

MAIDEN-

MAIDEN-*rents*, in our *Old Writers*, a noble paid by the tenants of some manors on their marriage. This was said to be given to the lord, for his omitting the cuſtom of marcheta, whereby he was to have the firſt night's lodging with his tenant's wife; but it ſeems more probably to have been a fine for a licence to marry a daughter.

MAJESTY, *majeſtas*, a title or quality given to kings; and which frequently ſerves as an appellation to diſtinguiſh them by.

The word ſeems compoſed of the two Latin words, *major*, *greater*, and *ſtatus*, *ſtate*.

The emperor is called, his Cæſarian or imperial *majeſty*; the king of Spain, his Catholic *majeſty*; the king of France, his moſt Chriſtian *majeſty*; the king of Great Britain, his Britannic *majeſty*, &c. Some have alſo extended this title to the popes.

Paſquier obſerves, that our forefathers uſed this quality very ſparingly; and that the frequent uſe of the word, which now obtains, had not its beginning before the reign of their Henry II. He inſtances ſeveral letters of St. Gregory, who, writing to king Theodoret and Theodoric, only compliments them with EXCELLENCY.

Till the time of Charles V. the king of Spain had no title but that of highneſs; Louis XI. was the firſt in France who aſſumed this title; and before our king Henry VIII. the kings of England were only addreſſed under the titles of grace, which began in the time of Henry IV. and excellent grace, under Henry VI. and HIGHNESS. See KING.

At the peace of Munſter, there was a great conteſt between the miniſters of the emperor and thoſe of France: the firſt would not allow the title of ſerenity to the king of France, and the latter would not give that of *majeſty* to the emperor. At laſt it was agreed, that, whenever the French king ſhould write with his own hand to the emperor, he ſhould give him the title of imperial *majeſty*; and reciprocally, when the emperor ſhould write to the king, he ſhould give him that of royal *majeſty*.

Under the Roman republic, the title *majeſty*, *majeſtas*, belonged to the whole body of the people, and to the principal magiſtrates; ſo that to diminiſh or wound the *majeſty* of the commonwealth, was to be wanting in reſpect to the ſtate, or to its miniſters. But the power afterwards palling into the hands of a ſingle perſon, the appellation of *majeſty* was tranſferred to the emperor, and the imperial family. Pliny complimente Trajan on his being contented with the title of greatneſs; and ſpeaks very invidiouſly of thoſe who affected that of *majeſty*. And yet *majeſty* ſeems to be the moſt modeſt and juſt title that can be attributed to ſovereigns, ſince it ſignifies no more than the royalty, or ſovereign power.

St. MAIEUL, *regular clerks of*. See FATHERS *of St. Maiolus*.

MAIL, *maille*, is primarily applied to the maſhes or holes in net-work.

MAIL, *coat of*. See COAT *of mail*.

It is called alſo a HABERGEON.

Anciently they alſo wore ſhirts of *mail* under the waiſtcoat, to ſerve as a defence againſt ſwords and poniards. We alſo read of gloves of *mail*.

MAIL, or MALL, alſo ſignifies a round ring of iron; whence the play of pall-mall, from *palla*, a *ball*, and *maille*, the round ring through which it is to paſs.

MAILLE, in our *Old Writers*, a ſmall kind of money. Silver half-pence were likewiſe termed *mailles*, 9 Hen. V. By indenture in the mint, a pound weight of old ſterling ſilver was to be coined into three hundred and ſixty ſterlings, or pennies, or ſeven hundred and twenty *mailes*, or half-pennies, or one thouſand four hundred and forty farthings. Hence the word *mail* was derived, which is now vulgarly uſed in Scotland to ſignify an annual rent. See GOLD-*coin*.

MAILS, on *Ship-board*, are ſquare machines, compoſed of a number of rings interwoven net-wiſe, and uſed for rubbing off the looſe hemp which remains on lines or white cordage, after it is made.

MAILED implies a thing ſpeckled, or full of ſpecks; as the feathers of hawks, partridges, &c. or the furs of ſome wild beaſts.

MAIN, a term applied to ſeveral parts of a ſhip, as the *main-capſtan*, *main-maſt*, *main-top-maſt*, *main-ſail*, &c. and ſignifying the chief or largeſt of the kind. See CAPSTAN, MAST, SAIL, &c.

MAIN-*body of an army*, is the body of troops that marches between the advance and the rear guard. In a camp it is that part of an army which is encamped betwixt the right and left wings.

MAIN-*guard*. See GUARD.

MAIN-MORTE, a term in ſome ancient cuſtoms, ſtill obtaining in Burgundy, ſignifying a right which the lord has, on the death of the chief of a family that is *mainmortable*, of taking the beſt moveable in the houſe; or, in default of that, the right hand of the deceaſed was offered him, in token that he could ſerve him no longer. See MORT-MAIN.

MAINIS, in *Ichthyology*, a name uſed by Ariſtotle, Athenæus, and others of the old Greek writers, for the fiſh now called the *mena*, *menerela*, and *menula*. It is a ſpecies of the SPARUS, and is diſtinguiſhed from all the other ſpecies of that genus, by having four large teeth, and a variegated body, ornamented with a black ſpot in the middle of the ſides. This is the ſth the Narbons call *ſaſſala*.

MAINOUR, MANOUR, or MEINOR, in *Law*, ſignifies the thing that a thief takes away, or ſteals.

Thus, to be taken with *mainour*, is to be taken with the thing ſtolen about him. If the defendant were taken with the *mainour*, and ſo carried to court, in ancient times they would arraign him on the *mainour*, without any appeal or indictment.

MAINPERNORS. See MAINPRISE.

MAINPRISE, compounded of the French *main*, *hand*, and *priſe*, or *prins*, *taken*, in *Law*, the taking or receiving a man into friendly cuſtody, who otherwiſe might be committed to priſon; upon ſecurity given for his forthcoming at a day aſſigned.

They who thus undertake for any one, are called *mainpernors*, becauſe they receive the perſon into their hands; whence alſo comes the word *mainpernable*, denoting the perſon who may be thus bailed. See BAIL.

The writ of *mainprize* is a writ directed to the ſheriff, (either generally, when any man is impriſoned for a bailable offence, and bail hath been refuſed; or ſpecially, when the offence or cauſe of commitment is not properly bailable below), commanding him to take ſureties for the priſoner's appearance, and to ſet him at large. Mainpernors differ from bail, in that a man's bail may impriſon or ſurrender him up before the ſtipulated day of appearance. Mainpernors can do neither, but are barely ſureties for his appearance at the day: bail are only ſureties, that the party be anſwerable for the ſpecial matter which they ſtipulate: mainpernors are bound to produce him to anſwer all charges whatſoever.

MAINTAINERS, are thoſe that maintain or ſecond a cauſe depending between others, by diſburſing money, or making friends for either party, &c. not being intereſted in the ſuit, or attornies employed therein. Stat. 19 Hen. VII. cap. 14. See MAINTENANCE.

MAINTENANCE, *manutenentia*, in *Law*, an unlawful maintaining, or officious intermeddling in a ſuit between others, by aſſiſting either party with money or otherwiſe, to proſecute or defend it.

The word is metaphorically taken from the ſuccouring a young child, that learns to go by one's hand; but it is uſed in the bad ſenſe in ſome of our ſtatutes.

By the Roman law, it was a ſpecies of the *crimen falſi* to enter into any confederacy, or do any act, to ſupport another's law-ſuit, by money, witneſſes, or patronage. A man may, however, maintain the ſuit of his near kinſman, ſervant, or poor neighbour, out of charity and compaſſion, with impunity: otherwiſe the puniſhment by common law is fine and impriſonment; and by ſtat. 32 Hen. VIII. cap. 9. a forfeiture of 10l. The puniſhment of BARATRY, or *barratry* in a common perſon, is alſo fine and impriſonment; but if the offender belongs to the profeſſion of the law, a barrator ought to be diſabled from practiſing for the future.

There lies a writ againſt a *maintainer*, called a writ of *maintenance*.

MAJOR, in *Logic*, is underſtood of the firſt propoſition of a regular ſyllogiſm.

It is called *major*, becauſe it has a more extenſive ſenſe than the *minor* PROPOSITION, as containing the principal term.

MAJOR *and minor*, in *Muſic*, are applied to concords which differ from each other by a ſemi-tone.

There are *major* and *minor* thirds, &c.

Major tone is the difference between the fifth and fourth; and *major* ſemi-tone the difference between the *major* fourth and the third. The *major* tone ſurpaſſes the *minor* by a comma. See TONE.

MAJOR, in *Law*, a perſon who is of age to manage his own affairs. See AGE.

By the civil law, a man is not a *major* till the age of twenty-five years; in England, he is a *major* at twenty-one, and in Normandy at twenty.

MAJOR, in the *Art of War*, a name given to ſeveral officers of different qualities and functions. Thus,

MAJOR-*general* is a general officer, who receives the general's orders, and delivers them out to the *majors* of brigades, with whom he concerts what troops are to mount the guard, what to go on parties, and what to form detachments, or to be ſent on convoys, &c.

It is his buſineſs alſo to view the ground to encamp on,

and do other ſervices; he is ſubordinate to the general and lieutenant-general; and the next commanding officer to them.

MAJOR *of a brigade*, either of horſe or foot, is he who receives orders, and the word, from the *major-general*; and gives them to the particular *majors* of each regiment. See BRIGADE-*major*.

MAJOR *of a regiment* is an officer, whoſe buſineſs is to convey all orders to the regiment, to draw it up, and exerciſe it, to ſee it march in good order, to look to its quarters, and to rally it, if it happen to be broken in an engagement, &c.

The *major* is next to ſubordination to the lieutenant-colonel, and generally promoted from the eldeſt captain. He is the only officer of a regiment of foot, who is allowed to be on horſeback in time of ſervice; but he always rides, that he may ſpeedily get from place to place, as occaſion requires.

MAJOR *of a regiment of horſe* is the firſt captain of the regiment; and commands in the abſence of the colonel.

MAJOR *of artillery* is the next officer to the lieutenant-colonel. In the field he receives daily orders from the brigade *major*, and communicates them, with the parole, to his ſuperiors, and then dictates them to the adjutant.

MAJOR *of engineers*. See ENGINEER.

MAJOR, *ſergeant*, is a non-commiſſioned officer, ſubordinate to the adjutant, as he is to the *major*.

MAJOR, *town*, is the third officer in order in a garriſon, being next to the deputy-governor.

He ought to underſtand fortification, and hath charge of the guards, rounds, patrols, and centinels.

There are alſo *aids-major*, *drums-major*, and other officers; ſo called, on account of ſome ſeniority or prerogative that they have over the reſt. See AID-*major*, and DRUM-*major*.

MAJOR, *fife*, has the ſame authority over the fifers as the *drum-major* has over the drummers. He teaches them their duty, appoints them for guards, &c.

MAJOR *helicis*, in *Anatomy*, a name given by Albinus to one of the muſcles of the eye, called by Santorini and others, *helicis muſculus*. This author diſtinguiſhes it under the name *major*, from another muſcle which he calls the *minor helicis*, and which Santorini calls only *fibræ muſculares in plana helicis ſucie*, though it be a true and proper muſcle.

MAJOR-DOMO, an Italian term, frequently uſed to ſignify a ſteward, or maſter of the houſhold.

The title of *major-domo* was formerly given in the courts of princes to three different kinds of officers. 1. To him who took care of what related to the prince's table, or eating; otherwiſe called *elector*, *præfectus menſæ*, *architriclinii*, *dapifer*, and *principis epulorum*. 2. *Major-domo* was alſo applied to the ſteward of the houſhold. 3. The title of *major-domo* was alſo given to the chief miniſter, or him to whom the prince deputed the adminiſtration of his affairs, foreign and domeſtic, relating to war as well as peace. Inſtances of *major-domos* in the two firſt ſenſes are frequent in the Engliſh, French, and Norman affairs.

MAJORANA, in *Botany*. See MARJORAM.

MAIZE, or INDIAN CORN, *zea*, in *Botany*, a genus of the *monœcia triandria* claſs. Its characters are theſe: it has male and female flowers, ſituated at remote diſtances on the ſame plant; the male flowers are diſpoſed in a looſe ſpike, having oval, oblong, chaffy empalements, opening with two valves, each including two flowers; theſe have two ſhort compreſſed nectariums, and three hair-like ſtamina, terminated by quadrangular ſummits, which open in four cells at the top; the female flowers, which are ſituated below the male, are diſpoſed in a thick ſpike, incloſed with leaves; theſe have thick chaffy empalements, with two valves; the flowers are compoſed of two ſhort membranaceous broad valves, which are permanent, and a ſmall germen, with a ſlender ſtyle, crowned by a ſingle ſtigma, which is hairy toward the point; the germen afterward turns to a roundiſh compreſſed ſeed, angular at the baſe, and half incloſed at its proper receptacle. Miller reckons three ſpecies, and Linnæus only one.

The Indians in New England, and many of our other ſettlements in America, had no other vegetable but *maize*, or Indian corn, for making their bread. They call it *nocake*; and where our colonies are at this time numerous, there is yet much of the bread of the country made of this grain, not of the European corn. In Italy and Germany alſo there is a ſpecies of *maize*, which is the food of the poor inhabitants.

The ear of the *maize* yields a much greater quantity of grain than any of our corn ears. There are commonly about eight rows of grain in the ear, often more, if the ground be good. Each of theſe rows contains at leaſt thirty grains, and each of theſe gives much more flour than a grain of any of our corn. The grains are uſually either white or yellowiſh, but ſometimes they are red, bluiſh, greeniſh, or olive-coloured, and ſometimes ſtriped and variegated.

This ſort of grain, though ſo eſſentially neceſſary to the natives of the place, is yet liable to many accidents. It does not ripen till the end of September; ſo that the rains often fall heavy upon it while on the ſtalk, and the birds, in general, peck it while it is ſoft and unripe. Nature has, to defend it from theſe accidents, covered it with a thick huſk, which keeps off ſlight rains very well; but the birds, if not frighted away, often eat through it, and devour great quantity of the grain.

There ſeem to be three or four diſtinct ſpecies of *maize* in different parts of America. That of Virginia is very tall and robuſt, growing to ſeven or eight foot high; that of New England is ſhorter and lower. And the Indians, farther up in the country, have a yet ſmaller kind in common uſe. The ſtalk of the *maize* is joined like the ſugar-cane; it is very ſoft and juicy, and the juice is ſo ſweet and ſaccharine, that a ſyrup, as ſweet as that of ſugar, has been often made of it; and things ſweetened with it have been found not diſtinguiſhable from thoſe done with ſugar. It has not been tried yet whether it will cryſtallize into ſugar; but in all probability it will.

The Americans plant this corn any time from the beginning of March to the beginning of June; but the beſt ſeaſon is the middle of April. The ſavage Indians, who knew nothing of our account of months, uſed to guide themſelves in the ſeed-time of this uſeful plant, by the budding of ſome particular trees of that country, and by the coming up of a ſort of fiſh into their rivers, which they call the *alooſe*. Theſe things were both ſo regular, that they were in no danger of miſtaking the time.

The manner of planting *maize* is in rows, at equal diſtances, every way about five or ſix feet. They open the earth with a hoe, taking away the ſurface to three or four inches deep, and of the breadth of the hoe; they then throw in a little of the finer earth, ſo as to leave the hoe four inches deep, or thereabouts, and in each of theſe holes they place four or five grains at a little diſtance from one another. If two or three of theſe grow up, it is very well; ſome of them are uſually deſtroyed either by the birds or other animals.

When the young plants appear, they hoe up the weeds from time to time; and when the ſtalk gathers ſome ſtrength, they raiſe the earth a little about it, and continue this at every hoeing, till it begins to put forth the ears; then they enlarge the hill of earth, round the root, to the ſize of a hop-hill, and after this they leave it till the time of harveſt, without any farther care.

When they gather the ears, they either immediately ſtrip off the corn, or elſe hang up the ears, tied in traces at diſtances from one another; for if they are laid near together, they will heat and rot, or elſe ſprout and grow; but kept cool and ſeparate, they will remain good all the winter. The beſt method is to threſh out the corn as ſoon as the harveſt is over, to dry it well on mats in the ſun, and then lay it up in holes of the ground, well lined with mats, graſs, or the like, and afterwards covered at top with more earth. The moſt careful among the Indians uſe this method, and this ſort of ſubterranean granary always proves good. See TRAGUS.

The uſes of this plant among the Indians are very many. The great article is the making their bread of it; but beſides this, the ſtalks, when cut up before they are too much dried, are an excellent winter food for cattle; but they uſually leave them on the ground for the cattle to feed on. The huſks about the ear are uſually ſeparated from the reſt, and make a particular ſort of fodder, not inferior to our hay. The Indian women have a way of ſlitting them into narrow parts, and they then weave them artificially into baſkets and many other toys.

The original way of eating the grain, among the Indians, was this; they boiled it whole in water till it ſwelled and became tender, and then they fed on it either alone, or eat it with their fiſh and veniſon, inſtead of bread. After this, they found the way of boiling it into a ſort of pudding, after bruiſing it in a mortar; but the way of reducing it to flour is the beſt of all. They do this by parching it carefully in the fire, without burning, and then beating it in mortars, and ſifting it. This flour they lay up in bags, as their conſtant proviſion, and take it out with them when they go to war, eating it either dry or with water.

The Engliſh have contrived, by mixing it into a ſtiff paſte, either by itſelf, or with rye or wheat-meal, fermenting it with leaven or yeaſt, and baking it in a hot oven, to make good bread of it. They have likewiſe found out a method of making good beer, either of the bread, or by malting the grain. Phil. Trans. N° 142. or Abridg. vol. ii. p. 630, &c.

MAKE, in *Law*, signifies to perform and execute.

Thus, to *make* his law, is to perform that law to which a man had formerly bound himself; *v. gr.* to clear himself of action commenced against him by his own oath, and the oath of his neighbours; otherwise called to wage law. See WAGER *of law*.

So, to *make* services, or customs, is nothing else but to perform what belongs to them.

MAKE-*hawk*, in *Falconry*. See HAWK.

To MAKE, in *Sea-language*, is variously applied: e. g. *to make a board*. See BOARD.

To make, the land is to discover it from a distant situation, in consequence of approaching it after a sea-voyage: to *make* land is to increase the quantity of sail already extended, either by letting out the reefs, and by hoisting an additional number of small sails, or by either of these operations separately: to *make* stern-way is to retreat or move with the stern foremost: to *make* water ealually signifies to leak; but a ship is said to *make* foul water, when running in shallow water, her keel disturbs the mud or ooze, lying at its bottom.

MAKINBOY, a name given by the people of Ireland to a kind of spurge, or tithymale, common there: this is a very violent purge, as all the other spurges are; but the Irish have an opinion, that it will produce this effect only by being carried in the pocket. This opinion, which had been universally believed for many ages, was proved to be false by Dr. Mullen, who carried a large quantity of it about him many days together, on purpose to give a fair trial; but it had not any the least effect on him.

MAKING *up*, a term used by the distillers to express the bringing spirits to a certain standard of strength by the addition of water. See LOWERING.

It is used principally in the distilling spirits, after their first drawing, either by way of rectifying them, or of giving them the virtues of aromatic ingredients, in order to make the compound waters; such as cinnamon, anniseed, and the like. See DISTILLATION.

In the making these compounds, some use an alcohol, or totally inflammable spirit, which is much the best method; others use ordinary proof spirit of malt, or molasses. If the latter be used, it is best not to put any water with it into the still; but if the former, so much water is to be added as will reduce it to the proof strength, which is just an equal quantity. When this is done, there should be drawn off three fifths of the whole by distillation; and the far better way would be to keep this liquor in this very state, which is just the strength of the trois cinques brandy of the French: but as people require these waters to be kept for drinking, in such a state as not to exceed, at the utmost, the strength of proof spirit, generally to fall much short of it, it is necessary to reduce this three fifths to the whole, or more than the whole quantity of the proof spirit put into the still. The apothecaries, to this end, usually let the still continue to work without changing the receiver, till an equal quantity is produced to the spirit put in, or one fourth more; it being the usual standard in these waters to have five quarts made from a gallon of the spirit. By the method of doing this, by letting the still run, the faints are taken into the water, and give it a vapid and disagreeable taste. Instead of this the distiller, when he has drawn off his three fifths of the quantity of proof, makes up the whole to the destined quantity, by adding the two other fifths, or more than that, if required, of common water, in which it is also customary to dissolve some fine sugar; and this gives a fulness in the mouth to the water, and makes it mellow, or lose the fiery taste of the still much sooner. If it be only made up to the strength of proof, it will mellow much sooner than if reduced one fifth below that standard, as the oil is much more perfectly dissolved in spirit of a standard proof strength, than in such as is weaker. The water employed in the *making up*, should be either soft and clear river water, or else spring-water rendered soft by distillation, otherwise it is apt to turn the water thick, and precipitate a sediment, especially if the water be drawn lower than proof, or if the spirit, originally employed, partake of an alkaline nature from the fats used in its rectification, as is usually the case in the malt spirits, the gross oil of which requires to be separated, by mixing fair of tartar or pot-ash with it in the still in the rectification.

When it is necessary to *make up* waters lower than proof, they are generally cloudy; but this may be remedied, and they may be fined down in a day or two with a small quantity of alum, or with whites of eggs, or the jelly of isinglass beat up to a froth, and mixed in the same manner as is usually done in the refining of wines.

The sugar, added to these cordial waters, has not only the advantages of mellowing and filling the mouth, but it unites the oil to the spirit in a manner that it could never be united in without it. Shaw's Eday on Distillery.

MALA *aurea*, in *Botany*, a name by which some authors have called the *poma amoris*, or fruit of the lycopersicon.

MALABAR *nut*, in *Botany*, a species of the JUSTICIA. See ADHATODA.

MALABATHRUM, among the *Ancients*, an excellent sweet-scented ointment.

MALABATHRUM, *Indian leaf*, in *Botany*. See TAMALAPATRA.

MALACCA *finces*, a name given by many authors to the *pedra del porco*, or *hog-bezoar*.

MALACHE, formed of μαλασσω, *I soften*, a term used by authors in a different sense; sometimes expressing such medicines as gently loosen the belly, and sometimes such ointments as relax and mollify.

MALACHI, *the prophecy of*, is one of the canonical books of the Old Testament, written by *Malachi*, who was probably contemporary with Nehemiah, and lived about 428 years before Christ. The chief corruptions which he charges upon the Jews are the same with those for which they were reproved by Nehemiah; he forbids them to expect any farther succession of prophets, exhorts them to observe the law of Moses, and predicts the coming of Elias or John the Baptist, as the fore-runner of the Messiah.

MALACHITES, or MOLOCHITES, in *Natural History*, a species of jasper, but of less beauty than most of those of that class. It is naturally of a pure and deep green, but sometimes variegated with whitish or blackish spots and clouds. It is found in the East and West Indies; also in many parts of Europe. See JASPER.

Its amuletic virtues, formerly in great esteem, are too ridiculous to be particularised. It is said to be a violent purgative, operating both by vomit and stool, and as such given in drachms. In so small a dose as five or six grains. If, as is very probable, its green colour be owing to particles of COPPER, it is not wonderful that it should have this effect; but there are so many better medicines for this purpose, as to supersede its use.

MALACHRA, in *Botany*, a genus of the *monadelphia pentandria* class; the characters of which are, that the calyx is three-leaved, and that the seeds, which are single, are covered with five coats. There are two species.

MALACIA, MALACIA, a disease consisting in a depraved appetite, wherein the patient covets and longs for some particular kind of food with extraordinary earnestness, and eats it to excess.

The word seems derived from the Greek μαλακια, *soft*; too lax a tone of the stomach being generally the occasion of indigestion, and of these unusual cravings.

Many authors confound this affection with another called PICA, which consists in a depravation of appetite, leading the patient to covet things unnatural and absurd, as lime, coals, &c.

The *malacia* seems to arise from an evil disposition of the menstruum in the stomach; or from some defect in the imagination, which determines it to some one thing rather than another.

MALACOCISSOS, in *Botany*, a name used by some authors for the common ground-ivy, or *hedera terrestris*; and by some others for the marsh-marygold.

MALACODERMATA, formed of μαλακος, *soft*, and δερμα, *skin*, in *Natural History*, a term used to express such animals as have only soft skins for their covering; in opposition to the ostracodermata, which have hard shelly matters for their covering, such as crabs, lobsters, &c.

MALACOIDES, in *Botany*. See *Bastard* MALLOW.

MALACOPTERYGII, in *Ichthyography*, the name of a large order of fishes, which have not prickly fins.

The term is derived from the Greek μαλακος, *soft*, and πτερυγιον, *a fin*. The fish of this order, are those which have bony fins, with all their extremities not pointed or sharp, but soft and harmless. Of this order are the carp, &c.

MALACOSTOMOUS, in *Ichthyography*, the name of a large genus of fishes, called in English the leather-mouthed kind. These fishes are wholly destitute of teeth in their jaws, but have them placed in their throats, near the orifice of the stomach.

The word is derived from the Greek μαλακος, *soft*, and στομα, *a mouth*. All the fish of this genus have their swimming, or air-bladder, divided into two parts; and of this genus are the carp, tench, bream, chub, and the like.

MALACOSTRACA, in *Natural History*, a term used by some, as Aristotle, to distinguish what we call crustaceous animals of the sea, &c. from those which he calls ostracodermata, or testaceous, as we express it. See table of testaceous and crustaceous animals. See CRUSTACEOUS.

MALAGMA, formed of μαλασσω, *I soften*, a word used by some authors to express a cataplasm in general, of whatever nature, or made of whatever ingredients; but some have used it only for the emollient cataplasms.

MALAN-

MALANDERS, *malandria*, a diſeaſe in horſes, ſo called from the Italian *malandrare*, *to go ill*.

It conſiſts in certain ulcerous chaps, or chinks, appearing on the inſide of the fore-legs, juſt againſt the bending of the knee, which void a red, ſharp, and pungent humour.

This diſtemper may be cured by waſhing the parts with a warm lather of ſoap, or old chamber-lye; and then applying over the cracks a ſtrong mercurial ointment, ſpread on tow, with which they ſhould be dreſſed night and morning, till all the ſcabs fall off; but if this treatment fail, make an ointment of half an ounce of æthiops mineral, one dram of white vitriol, ſix ounces of ſoft green ſoap; and having clipped off the hair, and cleared away the ſcabs, anoint often with this, and apply the above unguent over the ſores. When they dry up, give a gentle purge or two; or let the nitre-balls be taken for two or three weeks. Bartlet.

MALANKUA, in the *Materia Medica*, the name by which ſome authors have called the plant whoſe root is the round zedoary.

Many indeed eſteem the long and round zedoary the roots of different plants, but they ſeem rather to be only the different parts of the roots of the ſame ſpecies.

MALARMAT, in *Ichthyology*, a name given by authors to the fiſh called by ſome *lyra altera*, and *cornuta*. It is a ſpecies of the trigla, and is diſtinguiſhed by Artedi by the name of the trigla with many cirrhi, and with an octogonal body.

MALARUM *oſſa*, in *Anatomy*, are the cheek bones; they make the prominent upper part of the cheeks moſt remarkable in lean perſons: they form likewiſe a portion of the orbit, and complete the zygomatic arches. They have their name from the Latin *mala*, the *cheek*; they are two in number, and are ſituated in the lateral and middle parts of the face. They are, in ſome meaſure, triangular or irregularly ſquare, and are divided into two ſides, the external gently convex, the internal unequally concave.

The eminences in each bone are the ſuperior or angular orbitary apophyſis, which joins by future with the external angular apophyſis of the os frontis, and aſſiſts in forming the external angle of the orbit: from this apophyſis another ſubaltern proceſs runs inward on the inſide of the bone, one ſide of which forms a portion of the orbit, the other a portion of the zygomatic foſſa: the inferior or maxillary orbitary apophyſis, which with the angular apophyſis forms the inferior external portion of the orbit: the apophyſis malaris, which is in ſome meaſure the baſis of the reſt, and together with the apophyſis maxillaris, joins the orbitary apophyſis of the os maxillare, and the zygomatic apophyſis, which makes a part of the zygoma, and alſo of the zygomatic foſſa.

The cavities are the great orbitary ſlope, which makes the inferior external portion of the edge of the orbit; the zygomatic notch above the zygoma, and one or more little holes on the outſide, and in the orbitary apophyſis. Each bone is compoſed of two pretty compact tables, with a ſmall quantity of diploe between them, except in the anterior part of the apophyſis malaris. The os male on each ſide is joined to the os frontis by the angular apophyſis; to the os ſphenoides, by the ſubaltern apophyſis; to the os temporis, by the zygomatic apophyſis; and to the os maxillare, by its baſis. Winſlow's Anatomy, p. 34.

MALE, the ſex which has the parts of generation without-ſide, and which has ordinarily the pre-eminence over the other.

In this ſenſe *male* ſtands oppoſed to *female*.

For the proportion of *males* to *females*, ſee MARRIAGE.

MALE *baiſam apple*. See BALSAM-*apple*.

MALEBRANCHISM, the doctrine or ſentiments of father *Malebranche*, who was born at Paris in 1638, and became a prieſt of the Oratory of France in 1660, and died in 1715.

Malebranchiſm is in a great meaſure the ſame with CARTESIANISM. It muſt be owned, however, that though *F. Malebranche* thought the ſame with Deſcartes, yet he does not ſo properly ſeem to have followed him, as to have met with him.

Malebranchiſm is contained in the Recherche de la Verité; and, to give a general notion of it, we need only repeat what M. Fontenelle ſays of that work. The Inquiry after Truth, ſays he, is full of God: God is the only agent, and that too in the ſtricteſt ſenſe. All power of acting, all actions, belong immediately to him. Second cauſes are no cauſes. They are only occaſions that determine the action of God; or occaſional cauſes.

F. Malebranche, however, does not here lay down his ſyſtem entire, with regard to religion, or rather the manner in which he would reconcile religion to his ſyſtem of philoſophy; that he reſerved for his Entretiens Chrétiens, printed in 1677, where he proves the exiſtence of a God, the corruption of human nature by original ſin, and the neceſſity of a Mediator, and of grace.

Malebranchiſm, notwithſtanding, appears to many perſons not only ill-grounded, but even dangerous, and deſtructive to religion; and it has accordingly been vigorouſly oppoſed by many zealous French authors. The firſt was M. Foucher. After him came M. Arnaud; and in 1715, F. du Tertre, a Jeſuit, publiſhed an ample confutation (as he imagines) of his whole ſyſtem. It was alſo charged with atheiſm by F. Hardouin, in his Atheiſts Unmaſked; though his ſyſtem, formed by a warm and exuberant imagination, tends more to fanaticiſm and enthuſiaſm, than to atheiſm. That part which relates to our ſeeing all things in God, has been anſwered by Mr. Locke.

MALEDICTION, *maledictio*, in *Law*, a curſe uſually annexed to donations of lands, &c. to churches, and religious houſes; imprecating the moſt direful puniſhments on thoſe who ſhould infringe them.

MALICE, in *Ethics* and *Law*, is a formed deſign of doing miſchief to another; it differs from hatred. In murder, it is *malice* makes the crime; and if a man, having a *malicious* intent to kill another, in the execution of his *malice* kills a perſon not intended, the *malice* ſhall be connected to his perſon, and he ſhall be adjudged a murderer. The word *ex malitia præcogitata*, are neceſſary to an indictment of MURDER, &c. And this *malitia præcogitata*, or *malice prepenſe*, may be either expreſs or implied in law. Expreſs *malice* is, when one, with a ſedate, deliberate mind, and formed deſign, kills another; which formed deſign is evidenced by external circumſtances, diſcovering that intention; as lying in wait, antecedent menaces, former grudges, and concerted ſchemes to do him ſome bodily harm. Beſides, where no *malice* is expreſſed, the law will imply it; as where a man wilfully poiſons another, in ſuch a deliberate act the law preſumes *malice*, though no particular enmity can be proved. And if a man kills another ſuddenly, without any, or without a conſiderable provocation, the law implies *malice*; for no perſon, unleſs of an abandoned heart, would be guilty of ſuch an act, upon a ſlight or no apparent cauſe.

MALIGNANT, in *Medicine*, that quality in a diſeaſe which renders it more than ordinarily dangerous, and difficult of cure.

Malignant is generally applied to ſuch fevers as are epidemical, or infectious, and are attended with ſpots and eruptions of various kinds. See *Putrid* FEVER.

MALKARABALIA, in *Zoology*, the name of an Eaſt Indian ſpecies of ſerpent found in the iſland of Ceylon. It is remarkably variegated with white and duſky brown, in various figures.

MALL, or See-MALL, in *Ornithology*, the Engliſh name of a bird of the gull or larus kind, being the common gull, and diſtinguiſhed by authors by the name of *larus cinereus minor*, and called by Linnæus *larus canus*. It is very like the *larus cinereus major*, or HERRING-*gull*, but much ſmaller, not weighing above a pound; its head and neck are grey, with ſome brown ſpots; the lower part of the neck is white, the back is grey, and the breaſt and belly white as ſnow; the tail is alſo perfectly white, and is not forked. Theſe birds breed on the ledges of cliffs that hang over the ſea, and in winter are found in vaſt flocks on all our ſhores. See GULL.

MALLARD. See DUCK.

MALLEABLE, ſomething hard and ductile, and that may be beaten, forged, and extended under the hammer, without breaking.

All metals are *malleable*, not excepting even quickſilver; but gold is ſo in the greateſt degree of all. The chemiſts have long fought the fixation of mercury, or to render it *malleable*. See MERCURY, and FREEZING.

It is a popular error, that the art of making glaſs *malleable* was ever known; its nature is incapable of it. For if it were ductile, its pores would not be oppoſite to each other, and of conſequence it would not be tranſparent; ſo that its principal criterion would be loſt.

MALLEAMOTHE, in *Botany*, a low tree, or rather ſhrub, growing in Malabar. Of the roots are made hafts for knives, the leaves ſerve to dreſs the ground, and being fried in oil of palm, furniſh a liniment for removing the impetigo, and drying the puſtules of the ſmall pox. A decoction of the ſame, in common water, is uſed as a fomentation, to mitigate the pains of the hæmorrhoids.

The root pulverized with ginger and ſaffron, and exhibited in an infuſion of rice, cures the dropſy, by powerfully promoting a diſcharge of ſuperfluous ſerofities by the urinary paſſages. Acoſta commends the ſhrub principally for two effects; firſt, againſt ſtitches of the belly, for which purpoſe, however, it is of leſs efficacy than other

ther medicines; secondly, for curing all kinds of erysipelas, especially such as proceed from mere bile. They macerate the whole root or trunk, bruised in a decoction of rice, and suffer them to remain there for some hours, that the water may contract an acidity; after which they anoint the erysipelas therewith, and order the patient to drink a sufficient quantity of the same twice a day, the stomach being first purged. They give the same water to those who labour under an inflammation of the liver, and the burning heat of a fever; and use it mixed with a small quantity of the juice of the leaves of tamarind, to anoint the lips of the wounds, in order to prevent an inflammation.

MALLEMUCKE, in *Ornithology*. See FULMAR.

MALLEOLI, among the Romans, bundles of any combustible matter besmeared with pitch, and used by the Roman soldiers either for giving light in the night-time, or for setting fire to some of the enemies works.

The *malleoli* were sometimes fixed to a dart or javelin, that they might be sure to catch firm hold, and communicate the fire wherever they happened to light.

MALLEOLUS, a process in the lower part of the leg, just above the foot.

There is one *internal*, and another *external malleolus*.

The *internal malleolus* is an eminence of the tibia; the *external* of the fibula; the two together form the ancle. See *Anat. Chirurg. (Osteol.) fig.* 3. *n.* 23.

MALLEOLUS, in *Ichthyology*, a name given by Gaza and some others, to the fish called by Aristotle and the other old writers, *sphyræna*, and by the Italians *luccio marino*. It is a beautiful fish, and seems to belong to the scomber, or mackerel-kind. Salvian has figured it under the name of *pisciculus*, a name by which it is also called by Varro and some other old authors; but Salvian's figure is very imperfect; he has omitted the back fin.

MALLET, a large kind of hammer, made of wood, much used by artificers who work with a chissel, as sculptors, masons, and stone-cutters, whose *mallet* is ordinarily round; and by carpenters, joiners, &c. who use it square. See HAMMER.

There are several sorts of *mallets* used for different purposes on ship-board. The *caulking mallet* is chiefly employed to drive the oakum into the seams of a ship, where the edges of the planks are joined to each other in the sides, deck, or bottom. The head of this *mallet* is long and cylindrical, being hooped with iron to prevent it from splitting in the exercise of CALKING. There is also the *serving mallet*, used in serving the rigging, by binding the spun-yarn more firmly about it than could possibly be done by hand; which is performed in the following manner: the spun-yarn being previously rolled up in a large ball, or clue, two or three turns of it are passed about the rope, and about the body of the *mallet*, which for this purpose is furnished with a round channel in its surface, that conforms to the convexity of the rope intended to be served. The turns of the spun-yarn being strained round the *mallet*, so as to confine it firmly to the rope, which is extended above the deck, one man passes the ball continually about the rope, whilst the other, at the same time, winds on the spun-yarn by means of the *mallet*, whose handle acting as a lever, strains every turn about the rope as firm as possible. Falconer.

MALLEUM *incudis*, in *Anatomy*, a name given by Fabricius to one of the muscles of the ear, called by Cowper the *internus auris*, and by Albinus, who had considered its proper use, TENSOR *tympani*.

MALLEUS, in *Anatomy*, denotes one of the bones of the ear; so called from its resemblance to a hammer, or mallet; first discovered, as some assert, by Alexander Achillinus; though others have mistakenly attributed it to Jac. Carpensis. Vide Douglas Bibl. Anat. p. 48.

The *malleus*, or hammer of the ear, is a long bone with a large head, a small neck, a handle, and two apophyses, the one in the neck, the other in the handle. The top of the head is considerably rounded, and from thence it contracts all the way to the neck; both head and neck are in an inclined situation, and the eminences and cavities in it answer to those in the body of the incus. The handle is looked on by some as one of the apophyses of the *malleus*, and in that case it is the greatest of the three. It forms an angle with the neck and head, near which it is something broad and flat, and decreases gradually towards its extremity. The apophysis of the handle, terminated by others the small or short apophysis of the *malleus*, terminates the angle already mentioned, being extended toward the neck, and lying in a strait line with that side or border of the handle which lies next it. The apophysis of the neck, called also the apophysis gracilis, is in a natural state very long, but is slender withal, that it is very easily broken, especially when dry, which is the reason why the true length of it was for a long time unknown. It arises from the neck, and sometimes appears much longer than it really is, by the addition of a small dried tendon sticking to it. When the *mallei* is in its true situation, the head and neck are turned upwards and inwards, the handle downwards, parallel to the long leg of the incus, but more forward; the apophysis of the handle upwards and outward, near the superior portion of the edge of the tympanum, near the center of which is the extremity of the handle; and the apophysis gracilis forward, reaching all the way to the articular fissure in the os temporis. By the knowlege of this, the *mallei* of the right ear may be known from that of the left when out of their places. Winslow's Anat. p. 49. See EAR.

MALLOW, *mallow*, in *Botany*, a genus of the *monadelphia polyandria* class. Its characters are these: the flower has a double empalement, the outer composed of three, the inner of one leaf, cut into five broad segments at the brim; the flower is of one petal; it has a great number of stamina, which coalesce at bottom in a cylinder, but spread open above; in the center is situated an orbicular germen, supporting a short cylindrical style, with many briefly figmas; the empalement afterward turns to several capsules, which are joined in an orbicular depressed head fastened to the column, opening on their inside, each containing one kidney-shaped seed. Miller reckons fifteen, and Linnæus twenty-three species; two of which grow wild in most parts of England.

The fresh roots of the wild *mallow*, with a smooth leaf, are used as a diuretic and emollient, and the dried leaves as an ingredient in clysters, and in emollient fomentations and cataplasms. The ancients gave the juice of the *mallow*, in large doses, for inflammations and obstructions of the viscera. A strong decoction of *mallow* root is apt to be mucilaginous, and to fit ill on the stomach. It is a good common drink in pleurisies, peripneumonies, and peculiarly in cases of gravel, or inflammations of the kidneys; also in strangories and suppression of urine of all kinds. Infusions or decoctions of the leaves and flowers, and a conserve made by boiling the fresh flowers with thrice their weight of fine sugar, are sometimes prescribed for the same complaints.

MALLOW, *hastard*, *marsh*, in *Botany*, a genus of the *monadelphia polyandria* class. Its characters are these: the flower is shaped like that of the *mallow*, and hath a double empalement, the outer composed of three, and the inner of one leaf, cut into five segments; the flower is of one petal, divided into five parts to the bottom; in the center is situated the column, having a great number of stamina and styles joined closely to it; the germen becomes a fruit composed of many cells, which are collected into a head, in each of which is lodged a single seed. There is but one species, which has greatly the appearance of the *mallow*. Miller.

MALLOW, *Jews*, *corchorus*, in *Botany*, a genus of the *pentandria monogynia* class. Its characters are these: the flower, which is included in a five-leaved empalement, has five oblong blunt petals, and many hairy stamina, which are shorter than the petals; in the center is situated an oblong furrowed germen, which becomes a cylindrical pod, having five cells, which are filled with angular pointed seeds. Miller reckons five species, which, being natives of the East and West Indies, are too tender to thrive in the open air in England. Linnæus enumerates seven species.

The common *Jews mallow*, Rauwolf says, is cultivated about Aleppo as a pot-herb, and used by the Jews with their meat; and he supposes it to be the olus Judaicum of Avicenna, and the corchorum of Pliny.

A decoction of the whole plant, but especially of the leaves, is beneficial to the breast, by moistening it; for which reason, being taken with sugar-candy, it is a present remedy for rough and dry coughs.

MALLOW, *Indian*, *arum*, in *Botany*, a genus of the *monadelphia polyandria* class. Its characters are these: it hath a malvaceous flower, with a double empalement, the outer being of one leaf slightly cut at the brim into five parts, but the inner is five-leaved, permanent, and cut to the bottom; the flower is composed of five leaves, which are oblong, and blunt at their extremity, but narrow at their base, where they coalesce; in the center there are many stamina, which are joined, and form a column at their base, but spread open above; it has a roundish, five-cornered germen, with a single style, and ten hairy, reflexed stigmas; the germen changes to a pentagonal fruit, which is a berry, and divides into five cells, each having one angular seed. There are three species.

MALLOW, *Indian*, or *yellow*, *jute*, in *Botany*, a genus of the *monadelphia polyandria* class. Its characters are these: the empalement of the flower is single, permanent, angular, and five-pointed; the flower has one petal cut into five broad segments, joined at their base, and indented at their points; it has many stamina joined in a column at bottom, but spread open above, and an orbi-

culat germen, supporting a short multifid style; the germen becomes a five-cornered capsule, having five cells, each containing an angular roundish seed. There are twenty-one species.

MALLOW, *marsh*, *althea*, in *Botany*, a genus of the *monadelphia polyandria* class. Its characters are these: the flower has a double calyx; the outer cut into nine segments at the brim; the inner into five broad acute segments at the top; the flower has five petals, coalescing at their base, spreading open above, and shaped like a heart; there are many stamina, forming a kind of cylinder; in the center is placed the orbicular germen, supporting a short cylindrical style; the empalement becomes a compressed capsule, divided into several cells, each containing one compressed kidney-shaped seed. There are four species.

The common *marsh-mallow*, with single woolly leaves, indented in sharp segments, and growing naturally in moist places in many parts of England, though frequently cultivated in gardens, is perennial, and flowers from June to almost the end of summer.

The parts of this plant used in medicine, are the leaves and roots. The leaves, by decoction, afford a soft mucilaginous substance, good in all complaints arising from acrimony; of great service in dysenteries, &c. where the mucus of the intestines is raked off, and in many kinds of colics. It is also found of use in obstructions of the urinary passages, stranguries, heat of urine, &c. and is by some held a great secret for the cure of a gonorrhœa. Ray and others also speak of it as a pectoral; of use in coughs, and also pleurisies.

Marsh-mallow root is a very valuable medicine. It is emollient and diuretic, and gives great relief in disorders of the kidneys and bladder; whether arising from acrimony of the urine or gravel. It is good also in all disorders of the breast and lungs, arising from a thin acrimonious phlegm; in both which cases, a decoction of the fresh root is the best way of giving it. In diarrhœas and dysenteries, a strong decoction of *marsh-mallow* root, given clysterwise, is also of great use. Externally, in form of a cataplasm, it is excellent for softening and maturating hard tumors. The root is sometimes given in powders, from a scruple to a dram or two, either by itself, or in conjunction with other materials of a similar intention, as gum tragacanth, starch, &c.

The syrup of *marsh-mallows* is made by boiling a pound of the fresh roots in a gallon of water, till half the liquor is wasted, pressing out the decoction, and after settling for a night, boiling it down with four pounds of fine sugar, till the weight of the whole is six pounds; this is kept in the shops, and occasionally employed in some disorders of the breast, and for sweetening emollient decoctions in nephritic cases. This, however, is less efficacious than the decoction; on account of the sugar in the former, which makes an improper mixture with medicines of the mucilaginous kind.

Ointment of *marsh-mallows*, called *unguentum dialthææ*, is applied to tumors and inflammations, as an emollient and suppurative; which qualities it derives from the mucilage of the plant, being boiled a long time with the oil, before any of the other ingredients are mixed. See DIALTHEA.

The *emplastrum diachylon* receives much of its virtue from the same plant.

The *althea* of the ancients was plainly a different plant from that which we call by that name. Our *althea*, or *marsh-mallow*, is a very common plant, and grows in watery places, principally near the sea; but the *althea* of the ancients was a scarce herb, and grew in the barren deserts of Arabia, Asia, and the island of Sicily.

The descriptions, as we find them in the ancients, seem rather to refer us to the ABUTILON, or yellow *mallow* kind, than our own *althea*.

MALLOW, *rose*. See HOLLYHOCK.

MALLOW, *sea*, *malva marina*, in *Natural History*, a name not very judiciously given by some writers to a species of submarine substance, supposed in some degree to resemble the leaves of the common *mallow*. It is very common in the places where they fish for coral, and grows to the rocks without any regular root; it is found at different depths, but most usually far from the surface, and its height is usually about two inches: it is of a dusky greenish colour, with an admixture of a faint yellow; it is composed of several leaves of about half an inch broad, and a little more than that in length; each of these is fastened to a pedicle of about an inch and half long; the leaves are of a fine thin membranaceous substance, but their stalks or pedicles are thick and tough like horn. When examined by the microscope many glandules discover themselves upon the surfaces of the leaves, but the stalks or pedicles are entirely covered with glandules in form of small protuberances, which make it as rough in those parts as the common shagreen. The stalks when cut transversely shew an infinite number of pipes or vessels running up to every part of the leaves. Count Marsigli has given an elegant figure of this, both as it appears to the naked eye, and by the microscope.

MALLOW, *Syrian*, *hermia*, or *bibiscus*, in *Botany*, a genus of the *monadelphia polyandria* class. Its characters are these: the flower has a double permanent empalement; the outer has eight or ten narrow leaves; the inner is of one leaf, cut into five acute points; it has five heart-shaped petals, which join at their base into one; and many stamina, which are joined in form of a column, but expand toward the top; it has a round germen, which turns to a capsule with five cells, opening in five parts, including kidney-shaped seeds. There are twenty-five species of this plant propagated in gardens, where most of them grow to be shrubs of six or seven feet high; and, in the time of their flowering, which is during a great part of the latter end of the summer, they make a very beautiful figure. They may all be propagated by sowing their seeds in February or March on a light bed of earth; they must be suffered to remain in these beds till the following spring, being well weeded, and often watered in the summer. In the March following, the plants are to be transplanted into beds of the same sort of earth, setting them at about ten inches distance every way; here they are to remain two years more, being well weeded and watered in the time; and in the March following, they should be carefully removed to the places where they are to remain; they must be taken up carefully, without injuring the roots; the ground must be well watered where they are planted, and some mulch should be laid about their roots, to prevent the ground's drying too fast.

Some choose to propagate them by suckers from the old roots, but this is by no means advisable, as the plants this way raised are never well rooted, and are always subject to produce great numbers of suckers themselves, which renders them very unsightly.

The Historia Plantarum ascribed to Boerhaave, informs us, that all the species of this plant, except those which taste like sorrel, agree in virtue with the *mallow*.

MALLOW, *tree*, *variegated*, or *Venetian*. See LAVATERA.

MALLOW, *wall*, a species of the *mallow*, or common MALLOW. Some have called the ALCEA by this name.

MALLOW, *yellow*. See *Indian* MALLOW.

MALMIGNATTO, in *Natural History*, a name given by the inhabitants of the island of Corsica to a species of animal, or large insect, called by some *tarantula*, and ignorantly supposed to be the same with the tarantula of Apulia. This island produces neither wolves, serpents, nor many other of the mischievous and destructive animals which infest the neighbouring countries; but it produces two species of this venomous insect, called the *malmignatto*: the one of these has a round body, and the other an oblong one, resembling that of our large kind of ant; it has also six legs, not eight, and never makes any web; from all which it appears not to be a spider, but truly of the ant-kind, though a monstrous sized one, and very venomous. The round-bodied kind, by its bite, occasions violent pains, a sensation of coldness and cramps all over the body; and the long-bodied one is yet more venomous. Its sting occasions an immediate lividness of the flesh, with intolerable cramps and convulsions over the whole body; sometimes the natural evacuations by stool and urine are also wholly stopped by it. The cure, in both cases, is to be attempted by cutting and cauterizing the wound, and dressing it with Venice treacle, as also by giving the same in large doses dissolved in wine.

MALMSEY, or MALVASY, a rich luscious kind of wine brought from Greece or Candia; so called from Malvasia, a city in Peloponnesus, the ancient Epidaurus, whence this celebrated liquor was first brought.

That brought from Candia is now esteemed the best.

MALMSEY, or MALVISY, is also the name of a kind of muscadine wine brought from Provence.

MALOBATHRUM, among the Romans, a precious kind of ointment, brought from the Indies through Syria to Rome.

MALOGRANATUM, in *Botany*. See POMEGRANATE.

MALPIGHIA, in *Botany*. See *Barbadoes* CHERRY.

MALOPE, in *Botany*. See *Bastard* MALLOW.

MALPOLON, in *Zoology*, the name of a species of serpent found in the island of Ceylon, and beautifully variegated with red marks in the form of stars.

MALT denotes barley cured, or prepared to fit it for making a potable liquor, under the denomination of beer or ale. The manner of making *malt*, Sir Robert Murray describes as follows:—take good barley newly threshed, &c. put about six English quarters into a stone trough, or cistern lined with lead, full of water, where let it steep till the water be of a bright reddish colour; which will

be in about three days, more or leſs, according to the moiſture or dryneſs, and the ſmallneſs or bigneſs of the grain, and the ſeaſon of the year, or the temperature of the weather. In ſummer, *malt* never makes well; in winter, it requires longer ſteeping than in ſpring or autumn. It may be known when it is ſteeped enough, by other marks beſides the colour of the water; as by the exceſſive ſwelling of the grain, if it be over-ſteeped, and by too much ſoftneſs; being, when it is in a right temper, like the barley prepared to make broth of.

When it is ſufficiently ſteeped, take it out of the trough, and lay it on heaps to let the water drain from it; then after two or three hours turn it over with a ſcoop, and lay it in a new heap, about twenty or twenty-four inches deep.

This is called the *coming heap*, in the right management whereof lies the principal ſkill. In this heap it may lie forty hours, more or leſs, according to the fore-mentioned qualities of the grain, &c. before it comes to the right temper of *malt*; which that it may do equally, is the principal thing deſired.

While it lies in this heap, it muſt be carefully looked to, after the firſt fifteen or ſixteen hours; for about that time the grains begin to put forth roots: which when they have equally and fully done, the *malt* muſt within an hour after be turned over with a ſcoop; otherwiſe the grains will begin to put forth the blade or ſpire alſo, which muſt by all means be prevented. If all the *malt* do not come equally, but that which lies in the middle, being warmeſt, comes the ſooneſt, turn it, ſo that the outmoſt may lie inmoſt; and thus manage it till it be all alike.

As ſoon as the *malt* is ſufficiently come, turn it over, and ſpread it to a depth not exceeding five or ſix inches; and by that time it is all ſpread out, begin and turn it over and over again three or four times. Afterwards turn it over in like manner once in four or five hours, making the heap deeper by degrees; and continue ſo to do for the ſpace of forty-eight hours at leaſt. This frequent turning it over, cools, dries and deadens the grain; whereby it becomes mellow, melts eaſily in brewing, and ſeparates entirely from the huſk.

Then throw up the *malt* into an heap, at high as you can; where let it lie, till it grow as hot as your hand can endure it. This uſually comes to paſs in about thirty hours. This perfects the ſweetneſs and mellowneſs of the *malt*.

After it is ſufficiently heated, throw it abroad to cool, and turn it over again about ſix or eight hours after, and then lay it on a hair-cloth, or wire ſpread under it; where, after one fire, which muſt laſt for twenty-four hours, give it another more ſlow, and afterwards, if need be, a third; for, if the *malt* be not thoroughly dried, it cannot be well ground, neither will it diſſolve well in the brewing; but the ale it makes will be red, bitter, and unfit to keep.

The beſt fewel for drying it is peat, turf, or Welch coal, prepared by a previous burning; the next is charcoal. If there be not enough of one kind, burn the beſt firſt; for that gives the ſtrongeſt impreſſion. Phil. Tranſ. Abr. vol. ii. p. 627, &c. Indeed the beſt and moſt natural method of drying is in the ſun, in the months of April and May. This yields the paleſt, the moſt wholeſome, and the fineſt liquor. However this be, take care the *malt* be not ſmoked in the drying. As to the complexion or colour of *malt*, the white is accounted the beſt, becauſe the moſt natural. Brown malt is dried with ſtraw for London Porter.

The ſtrength and duration of the fire are different according as the *malt* is intended to be dried pale, amber, or brown. Pale and amber *malt* are dried with coke or culm, which, not emiting any ſmoke, give the *malt* a brighter colour, and do not impart that bad taſte which *malt* has when dried with wood, ſtraw, &c. Coke is beſt, becauſe its fire gives a ſteady and conſtant heat, whereby the *malt* is dried uniformly. If wood, or any vegetable fuel is uſed, it ſhould be extremely well dried, that it may yield the leſs ſmoke.

Almoſt every maſter has his ſecret in making *malt*, but there are ſome neceſſary cautions to be obſerved by all, which will enſure ſucceſs in the work; theſe are, 1. That the barley be newly thraſhed, or at leaſt newly winnowed. 2. That the whole be of one kind, not mixed up of ſeveral ſorts. 3. That it be not over-ſteeped in the ciſtern, or ſo long as to make it ſoft. 4. That it be well drained. 5. That it be carefully looked after in the wet couch, ſo as to ſtop the firſt tendency of the blade to ſhooting. 6. To turn the wet couch inſide outermoſt, if the barley comes, that is, ſhoots more in the middle than on the ſides. 7. To keep it duly turning after it is out of the wet couch. 8. To give it the proper heating in the dry heap. 9. To dry and criſp it thoroughly on the kiln, but without a fierce fire, ſo as to be ſeveral days in drying a kiln of pale *malt*. Shaw's Lectures, p. 187.

By 12 Ann. ſtat. 1. cap. 2, continued yearly, and by 33 Geo. II. cap. 7, there ſhall be paid by the maker for all *malt* made in England, except it be made for exportation only 12 Geo. cap. 4, 2 duty of nine pence a buſhel: and by 19 Geo. III. cap 25, an additional duty of 15*l.* per cent. which duty is under the management of the commiſſioners and officers of exciſe. No *malt* ſhall be imported, on pain of forfeiting the ſame and its value. *Aſalt* brought from Scotland ſhall be entered at the port of landing, and pay the ſame duty as Engliſh *malt*, unleſs a certificate is produced that it hath paid the duty of 4½ *d.* a buſhel in Scotland, and then it ſhall only pay 4½ *d.* more, to make it equal with the Engliſh. Places for making *malt* are to be entered, on pain of 50*l.* and the officers ſhall be permitted to enter and ſurvey, without interruption, on forfeiture of 20*l.* By 2 and 3 Edw. VI. cap. 12. no perſon ſhall make any barley *malt*, except in June, July and Auguſt, which ſhall not be three weeks at leaſt in making; nor in theſe months, under ſeventeen days, on pain of forfeiting *ſix* every quarter 2*l.* and ſelling *malt*, which has not been well dreſſed, ſo that there may not be ſanned out of one quarter half a peck of duſt or more, incurs a forfeiture of 20*s.* for every quarter: and mixing bad *malt* with good for ſale is liable to a forfeiture of 2*l.* for every quarter. In the proceſs of malting, preſſing *malt* in the ciſtern to prevent its ſwelling, mixing corn of one wetting with corn of a former wetting, and mixing *malt* with unmalted corn, incur each of them a penalty of 5*l.* a buſhel. 1 Geo. III. cap. 3. 12 Geo. II. cap. 1. 1. Geo. I. 2. cap. 2. Again, mixing *malt* that has been gaged with the ungaged, ſubjects to a forfeiture of 10*l.* 1 Geo. III. cap. 3. By the ſame ſtatute the ſame penalty is inflicted on thoſe who conceal *malt* to avoid being gaged in the couch: and by 12 Ann. ſtat. 1. cap. 2. concealing *malt* to avoid the duty incurs a forfeiture of 10*l.* a buſhel: and an allowance ſhall be made of four buſhels out of twenty for the ſwelling of *malt*, within thirty hours after the ſame ſhall be thrown out of the ſteeping veſſel, and ten buſhels out of twenty, after it hath been thrown out of the ciſtern thirty hours or more. But a maltſter, not covering his barley, &c. in the ciſtern with water, and ſuffering it to remain for forty hours, ſhall not be allowed the ſaid four buſhels in every twenty. The maltſter is required to give twenty-four hours notice within a city or market-town, and elſewhere forty-eight hours notice in writing to the officer of the time of the day when he intends to wet corn to be made into *malt*; and he ſhall not begin but between four in the morning and nine in the evening: the omiſſion of ſuch notice, &c. incurs a forfeiture of 100*l.* by 3 Geo. III. cap. 13. and by 12 Ann. ſtat. 1. cap. 2. he ſhall every month make entry at the office of Exciſe of all the *malt* made in ſuch month, on pain of 10*l.* within four months after entry, he ſhall pay off the duties, on pain of forfeiting double. 1 Geo. ſtat. 2. cap. 2.

A drawback of the duty is allowed for *malt* damaged in exportation, and alſo for *malt* deſtroyed by fire or water. A compoſition of 7*s.* and 6*d.* a head by the year ſhall be made for the duties of *malt* made to be conſumed in private houſes; and the houſes of perſons thus compounding ſhall not be liable to the duty or to the ſurvey of the officers: a perſon tranſgreſſing in this reſpect ſhall forfeit 5*l.* loſe the benefit of his compoſition, and forfeit for every buſhel of *malt* 20*s.* 12 Ann. ſtat. 2. cap. 2. 33 Geo. II. cap. 7. By the laſt ſtat. and 12 Geo. cap. 4. no *malt* entered and made for exportation ſhall be liable to the duties, and no drawback ſhall be allowed for any *malt* exported: but the maker ſhall be allowed for his trouble 3*d.* for every quarter. By 1 Geo. III. cap. 3. there ſhall be allowed for every twenty quarters of grain made into *malt* for exportation thirty quarters of *malt* and no more, on exportation: and notice ſhall be given of ſteeping and the quantity, on pain of 50*l.* and this ſhall be kept ſeparate from that deſigned for home conſumption, on pain of 5*l.* a buſhel, 12 Geo. cap. 4. and the corn of one ſteeping ſhall be kept ſeparate from any other, until it hath been meaſured, on pain of 50*l.* 3 Geo. II. cap. 7. Perſons oppoſing officers ſhall forfeit 50*l.* 12 Geo. cap. 4. Notice of meaſuring ſhall be given; and the *malt* carried on ſhip-board, or kept ſeparate and locked up, on pain of 50*l.* Opening ſuch locks, and carrying away the *malt*, without conſent of the officer, or notice given to him, incur a forfeiture of 100*l.* The officer having received forty hours notice ſhall attend, keep an account of the *malt* delivered out, and of the perſon to whom it belongs, and give a certificate to the officer of the diviſion to which it is to be removed, who ſhall file the ſame and make entry thereof: and if the proprietor neglect to deliver ſuch certificate, he ſhall forfeit 50*l.* Thoſe intending to

ſhip *malt* for exportation ſhall give forty-eight hours notice to the officer of the port in writing, with the name of the ſhip, on pain of 5*l.* a buſhel. The ſhip ſhall be locked, and perſons breaking open the hatches, forfeit 50*l.* The landing *malt* after ſhipping for exportation, ſubjects, beſides the penalty of the bond for its exportation, to a forfeiture of the ſame, and treble the value, 1 Geo. III. cap. 3. Storehouſes ſhall be cleared out in fifteen months, on pain of 50*l.* and unmalted oats or barley mixed among *malt* for exportation incurs a forfeiture of 5*l.* a buſhel, 6 Geo. cap. 21. See MALT TAX. For the duty on barley. See HORDEUM. The infuſion of *malt* has been much recommended as an antiſcorbutic. See SCURVY and WORT.

Good *malt* may be made of the grain of the maiz or Indian corn, but then a particular method muſt be taken for the doing it. Our barley *malt*-makers have tried all their ſkill to make good *malt* of it in the ordinary way, but to no purpoſe; that is, the whole grain will not be this way malted or rendered tender and flowry, as in other *malt*; for it is found, by experience, that this corn, before it be fully malted, muſt ſprout out both ways, that is, both root and blade, to a conſiderable length, that of a finger at leaſt, and if more the better. For this purpoſe it muſt be laid in a heap a convenient time; and in this proceſs, if it be of a ſufficient thickneſs for coming, it will quickly heat and grow mouldy, and the tender ſprouts will be ſo entangled, that the leaſt moving of the heap will break them off; and the farther maturation of the grain into *malt*, will be hindered by this means; and on the other hand, if it be laid thin, and often ſtirred and opened to prevent too much heating, thoſe ſprouts which have begun to ſhoot ceaſe growing, and conſequently the corn again ceaſes to be promoted to the mellowneſs of *malt*. Phil. Tranſ. N° 142.

To avoid all theſe difficulties, the following method is to be uſed: take away the top of the earth in a garden or field, two or three inches, throwing it up half one way, and half the other; then lay the corn for *malt* all over the ground ſo as to cover it; the earth that was pared off is now to be laid on again, and nothing more is to be done till the field is all over covered with the green ſhoots of the plant. The earth is then to be taken off, and the roots of the grain will be found ſo entangled together, that they will come up in large cakes or parcels; it muſt be gently waſhed in order to take off all the dirt, and then dried on a kiln, or on a clean floor expoſed to the ſun. Every grain of the maiz will be thus tranſmuted into good *malt*, and the beer brewed with it will be very pleaſant and very wholeſome, and of an agreeable brown colour, but very clear.

It may be worth trying whether the ſame proceſs is not with due care applicable to the malting of turneps, potatoes, carrots, parſneps, and the like. It might poſſibly be of ſervice alſo to attempt this leſs laborious way of making *malt* of barley and other ſmall grains: the diſadvantages would be the not ſo eaſily ſeparating the dirt from the grain as in that larger kind; and as barley requires the root only, not the ear, to ſhoot in order to the making of *malt*, it would be ſome difficulty to know the exact time of taking it up; but with all theſe diſadvantages the method is worth a trial.

MALT *for the manner of preparing liquors of*, ſee BREWING.

MALT *liquors* have different names as well as different virtues, properties, and uſes, both from the different manners of preparing the *malt*; whence they are diſtinguiſhed into *pale* and *brown*; and from the different manners of preparing or brewing the *liquors* themſelves; whence they are divided into *beer* and *ale*, *ſtrong* and *ſmall*, *new* and *old*.

Malt drinks are either pale or brown, as the *malt* is more or leſs dried on the kiln; that, which is the ſtendereſt dried, tinging the liquor leaſt in brewing, and therefore being called *pale*: whereas that higher dried, and as it were roaſted, makes it of a higher colour. A mixture of both theſe makes an amber colour; whence ſeveral of theſe liquors take their name.

Now, it is certain, the pale *malt* has moſt of the natural grain in it, and is therefore the moſt nouriſhing; but, for the ſame reaſon, it requires a ſtronger conſtitution to digeſt it. Thoſe who drink much of it, are uſually fat and ſleek in their bloom, but are often cut off by ſudden fevers; or, if they avoid this, they fall early into a diſtempered old age.

The brown *malt* makes a drink much leſs viſcid, and fitter to paſs the ſeveral ſtrainers of the body; but, if very ſtrong, it may lead on to the ſame inconveniencies with the pale; though a ſingle debauch wears off much more eaſily in the brown.

Dr. Quincy obſerves, that the beſt pale *malt liquors* are thoſe brewed with hard waters, as thoſe of ſprings and wells; becauſe the mineral particles, wherewith theſe waters are impregnated, help to prevent the coheſions of thoſe drawn from the grain, and enable them to paſs the proper ſecretions the better; as the viſcid particles of the grain do likewiſe defend theſe from doing the miſchief they might otherwiſe occaſion. But ſofter waters ſeem beſt ſuited to draw out the ſubſtance of high-dried *malts*, which retain many fiery particles in their contexture, and are therefore beſt left in a ſmooth vehicle.

For the differences in the preparation of *malt liquors*, they chiefly conſiſt in the uſe of hops, as in beer; or in the more ſparing uſe of them, as in ale.

The difference made by hops is beſt diſcovered from the nature and quality of the hops themſelves: theſe are known to be a ſubtile grateful bitter; in their compoſition, therefore, with this *liquor*, they add ſomewhat of an alkaline nature, *i. e.* particles that are ſublime, active, and rigid. By which means, the ropy, viſcid parts of the *malt* are more divided and ſubtilized; and are therefore not only rendered more eaſy of digeſtion and ſecretion in the body, but alſo, while in the *liquor*, they prevent it from running into ſuch coheſions as would make it ropy, vapid, and ſour.

For want of this, in unhopped drinks, that clammy ſweetneſs, which they retain after working, ſoon turns them acid, and unfit for uſe; which happens ſooner or later, in proportion to the ſtrength they receive from the *malt*, and the comminution that has undergone by fermentation.

It is a common opinion, that ale is more diuretic than beer, that is, liquor leſs hopped more than that with a greater quantity of hops in it: which may hold in ſome conſtitutions, becauſe ale being more ſmooth, ſoftening, and relaxing, where urine is to be promoted by enlarging the paſſage, as in thin, dry conſtitutions, this is the moſt likely to effect it. But, where the promoting of urine is to be done by attenuating and breaking the juices, and rendering them more fluid, it is certainly beſt anſwered by thoſe drinks which are well hopped.

As to the diſpute, whether or no hops tend to breed the ſtone; it is too long to enter upon here. Quincy is of opinion, there is but little reaſon for the affirmative ſide of the queſtion; and in the general, makes no ſcruple to ſay, that, for one conſtitution damaged by beer, there are numbers ſpoiled by ale. This laſt manifeſtly fouls the glands, ſtuffs the veſſels with ſlime and viſcidity, makes the body unwieldly and corpulent, and paves the way for cachexies, jaundice, aſthmas, and at laſt incurable dropſies. The urinary paſſages, alſo, which it is ſuppoſed to clear, will, in time, be filled by it with ſlough, and matter of as ill conſequence as gravel.

The different ſtrengths of *malt liquors* alſo make their effects different. The ſtronger they are, the more viſcid parts they carry into the blood; and though the ſpirituous parts make theſe imperceptible at firſt, yet when thoſe are evaporated, which will be in a few hours, the other will be ſenſibly felt by pains in the head, nauſeouſneſs at the ſtomach, and laſſitude or liſtleſſneſs to motion. This, thoſe are the moſt ſenſible of, who have experienced the extremes of drinking theſe *liquors*, and wines; for a debauch of wine they find much ſooner worn off, and they are much more lively and brisk afterwards, than after ſuddling *malt liquors*, whoſe viſcid remains will be long before they be ſhaken off.

Malt liquors therefore are, in general, the more wholeſome for being ſmall; *i. e.* of ſuch a ſtrength as is liable to carry a ſmall degree of warmth into the ſtomach, but not ſo great as to prevent their being proper diluters of the neceſſary food. Indeed, in robuſt people, or thoſe who labour hard, the viſcidities of the drink may be broken into convenient nouriſhment; but in perſons of another habit and way of living, they ſerve rather to promote obſtructions and ill humours.

The age of *malt liquors* is the laſt thing by which they are rendered more or leſs wholeſome. Age ſeems to do nearly the ſame thing as hops; for thoſe *liquors* which are longeſt kept are certainly leaſt viſcid; age breaking the viſcid parts, and, by degrees, rendering them ſmaller, and fitter for ſecretion.

But this is always determined according to their ſtrength; in proportion to which, they will ſooner or later come to their full perfection, as well as decay; for, when ale or beer is kept till its particles are broken and comminuted as far as they are capable, then it is that they are beſt; and, beyond this, they will be continually on the decay, till the finer ſpirits are entirely eſcaped, and the remainder becomes vapid and ſour.

MALT *Diſtillery*. This is an extenſive article of trade, and by which very large fortunes are made. The art is to convert fermented *malt* liquors into a clear inflammable ſpirit, which may be either ſold for uſe in the common ſtate of a proof ſtrength, that is, the ſame ſtrength with French brandy;

brandy; or is rectified into that purer spirit usually sold under the name of spirit of wine; or made into compound cordial waters, by being distilled again from herbs and other ingredients. See BREWING and WASH.

To brew with *malt* in the most advantageous manner, it is necessary, 1. That the subject be well prepared. 2. That the water be suitable and duly applied; and, 3. That some certain additions be used, or alterations made, according to the season of the year, and the intention of the operator; and by a proper regulation in these respects, all the fermentable parts of the subject will thus be brought into the tincture, and become fit for fermentation.

The due preparation of the subject consists in its being justly *malted* and well ground. When the grain is not sufficiently *malted* it is apt to prove hard, so that the water can have but very little power to dissolve its substance; and if it be too much *malted*, a part of the fermentable matter is lost in that operation. The harder and more flinty the *malt* is, the finer it ought to be ground; and in all cases, when intended for distillation, it is advisable to reduce it to a kind of finer or coarser meal. When the *malt* is thus ground, it is found, by experience, that great part of the time, trouble and expence of the brewing is saved by it, and yet as large a quantity of spirit will be produced; for thus the whole substance of the *malt* may remain mixed among the tincture, and be fermented and distilled among it. This is a particular that very well deserves the attention of the *malt* distiller, as that trade is at present carried on; for the dispatch of the business, and the quantity of spirit procured, is more attended to, than the purity or perfection of it.

The secret of this matter depends upon the thoroughly mixing, or briskly agitating and throwing the *meal* about, first in cold, and then in hot water; and repeating this agitation after the fermentation is over, when the thick turbid wash being immediately committed to the still, already hot and dewy with working, there is no danger of burning, unless by accident, even without the farther trouble of stirring, which in this case is found needless, though the quantity be ever so large, provided that requisite care and cleanliness be used; and thus the business of brewing and fermenting may very commodiously be performed together, and reduced to one single operation. Whatever water is made choice of, it must stand in a hot state upon the prepared *malt*, especially if a clear tincture be desired, but a known and very considerable inconvenience attends its being applied too hot, or too near to a state of boiling, or even scalding with regard to the hand. To save time in this case and to prevent the *malt* running into lumps and clods, the best way is to put a certain measured quantity of cold water to the *malt* first; the *malt* is then to be stirred very well with this, so as to form a sort of thin uniform paste or pudding; after which the remaining quantity of water required may be added in a state of boiling, without the least danger of making what, in the distillers language, is called a pudden.

In this manner the due and necessary degree of heat in the water, for the extracting all the virtues of the *malt*, may be hit upon very expeditiously, and with a great deal of exactness, as the heat of boiling water is a fixed standard which may be let down to any degree by a proportionate mixture of cold water, due allowances being made for the season of the year, and for the temperature of the air.

This little obvious improvement added to the method just above hinted for the reducing brewing and fermentation to one operation, will render it practicable to very considerable advantage, and the spirit improved in quality as well as quantity.

A much more profitable method than that usually practised for the fermenting *malt* for distillation, in order to get its spirit, is the following: take ten pounds of *malt* reduced to a fine meal, and three pounds of common wheat-meal; add to these two gallons of cold water, and stir them well together, then add five gallons of water boiling hot, and stir all together again. Let the whole stand two hours, and then stir it again, and when grown cold, add to it two ounces of solid yeast, and set it by loosely covered in a warmith place, to ferment.

This is the Dutch method of preparing what they call the wash for *malt* spirit; whereby they save much trouble and procure a large quantity of spirits: thus commodiously reducing the two businesses of brewing and fermenting to one single operation. In England the method is to draw and wash for spirit as they ordinarily do for beer, only instead of boiling the wort, they pump it into large coolers, and afterwards run it into their fermenting back, to be there fermented with yeast. Thus they bestow twice as much labour as is necessary, and lose a large quantity of their spirit by leaving the gross bottoms out of the still for fear of burning.

All simple spirits may be considered in the three different states of low wines, proof spirit, and alcohol, the intermediate degrees of strength being of less general use; and they are to be judged of only according as they approach to, or recede from these. Low-wines, at a medium, contain a sixth part of pure inflammable spirit, five times as much water as spirit necessarily arising in the operation with a boiling heat. Proof goods contain about one half of the same totally inflammable spirit; and alcohol entirely consists of it.

Malt low-wines, prepared in the common way, are exceeding nauseous; they have, however, a natural vinosity, or pungent agreeable acidity, which would render the spirit agreeable to the palate, were it not for the large quantity of the gross oil of the *malt* that abounds in it. When this oil is detained in some measure from mixing itself among the low-wines, by the stretching a coarse flannel over the neck of the still, or at the orifice of the worm, the spirit becomes much purer in all respects; it is less fulsome to the taste, less offensive to the smell, and less milky to the eye. Shaw's Essay on Distillery. When these low-wines, in the rectification into proof spirits, are distilled gently, they leave a considerable quantity of this gross fetid oil behind them in the still along with the phlegm; but if the fire be made fierce, this oil is again raised and brought over with the spirit; and being now broken somewhat more fine, it impregnates it in a more nauseous manner than at first. This is the common fault both of the *malt* distiller and of the rectifier; the latter, instead of separating the spirit from this nasty oil, which is the principal intent of his process, attends only to the leaving the phlegm in such quantity behind, that the spirit may be of a due strength as proof or marketable goods, and brings over the oil in a worse state than before. To this inattention to the proper business of the process, it is owing, that the spirit after its several rectifications, as they are miscalled, is often found more stinking than when delivered out of the hands of the *malt* distiller. All this may be prevented by the taking more time in the subsequent distillations, and keeping the fire low and regular, the sudden stirring of the fire, and the hasty way of throwing on the fresh fuel, being the general occasions of throwing up the oil by spurts, where the fire in general, during the process, has not been so large as to do that mischief.

The use of a balneum mariæ, instead of the common still, would effectually prevent all this mischief, and give a purer spirit in one rectification, than can otherwise be procured in ten, or indeed according to the common methods at all.

Malt low-wine, when brought to the standard of proof spirit, loses its milky colour, and is perfectly clear and bright, no more oil being contained in it than is perfectly dissolved by the alcohol, and rendered miscible with that proportion of phlegm, which is about one half the liquor; its taste also is cleaner, though not more pleasant; there being less of the thick oil to hang on the tongue in its own form, which is not the case in the low-wines, where the oil being undissolved, adheres to the mouth in its own form, and does not pass lightly over it.

When proof-spirit of *malt* is distilled over again, in order to be rectified into alcohol, or, as we usually call it, spirits of wine, if the fire be raised at the time when the faints begin to come off, a very considerable quantity of oil will be raised by it, and will run in the visible form of oil from the nose of the worm. This is not peculiar to *malt* spirit, but the French brandy shews the same phenomenon, and that in so great a degree, that half an ounce of this oil may be obtained from a single piece of brandy.

Malt spirit, more than any other kind, requires to be brought into the form of alcohol, before it can be used internally, especially as it is now commonly made up in the proof state, with as much of this nauseous and viscous oil as will give it a good crown of bubbles. For this reason it ought to be reduced to an alcohol, or totally inflammable spirit, before it is admitted into any of the medicinal compositions. If it be used without this previous caution, the odious taste of the *malt* oil will be distinguished among all the other flavours of the ingredients.

Malt spirit, when it has once been reduced to the true form of an alcohol, is afterwards more fit for all the curious internal uses than even French brandy, it being after this purification a more uniform, hungry, tasteless, and impregnable spirit, than any other spirits which we esteem so much finer.

A pure spirit being thus procured, should be kept carefully in vessels of glass or stone, well stopped, to prevent the

the evaporation of any of its volatile part. If preserved in casks, it is apt to impregnate itself very strongly with the wood. The quantity of pure alcohol obtainable from a certain quantity of *malt*, differs according to the goodness of the subject, the manner of the operation, the season of the year, and the skilfulness of the workman; according to which variations, a quarter of *malt* will afford from eight or nine, to thirteen or fourteen gallons of alcohol. This should encourage the *malt* distiller to be careful and diligent in his business, as to very large a part of his profit depends wholly on the well conducting his processes.

After every operation in this business, there remains a quantity of faints, which in their own coarse state ought never to be admitted into the pure spirit; these are to be saved together, and large quantities of them at once wrought into alcohol. It is easy to reduce these to such a state, that they will serve for lamp spirits. Their disagreeable flavour being corrected by the adding of aromatics during the diftillations, the reducing them into a perfect and pure alcohol is practicable, but not without such difficulties as render it scarce worth the trader's while. One way of doing it is by diftilling them from water into water, and that with a very flow fire. By this means a pure alcohol may be made out of the foulest faints.

The *malt* diftiller always gives his spirit a single rectification *per ſe*, in order to purify it a little, and make it up proof, but in this state it is not reckoned fit for internal uſes, but ſerves to be diftilled into geneva and other ordinary compound ſtrong waters for the vulgar.

The Dutch who carry on a great trade with *malt ſpirit*, never give it any farther rectification than this, and it is, on this account that the *malt ſpirit* of England is in general ſo much more in eſteem. The Dutch method is only to diſtil the wash into low wines, and then to full proof ſpirit; they then directly make it into geneva, or elſe ſend it as it is to Germany, Guinea, and the Eaſt-Indies, for the Dutch have little notion of our rectification. Their ſpirit is by this means rendered very foul and coarſe, and is rendered yet more nauſeous by the immoderate uſe they make of rye meal. *Malt* ſpirit, in its unrectified ſtate, is uſually found to have the common bubble proof, as the *malt* diſtiller knows that it will not be marketable without it.

The whole matter requiſite to this is, that it have a conſiderable portion of the groſs oil of the *malt* well broke and mixed along with it; this gives the rectifier a great deal of trouble if he will have the ſpirit fine; but in the general run of the buſineſs, the rectifier does not take out this oil, but breaks it finer, and mixes it faſter in by alkaline ſalts, and diſguiſes its taſte by the addition of certain flavouring ingredients. The ſpirit loſes in theſe proceſſes the vinoſity it had when it came out of the hands of the *malt* diſtiller, and is in all reſpects worſe, except in the diſguiſe of a mixed flavour. Shaw's Eſſay on Diſtillery.

The alkaline ſalts uſed by the rectifier, deſtroying the natural vinoſity of the ſpirit, it is neceſſary to add an extraneous acid in order to give it a new one. The acid they generally uſe is the *ſpiritus nitri dulcis*; and the common way of uſing it is the mixing it to the taſte with the rectified ſpirit: this gives our *malt* ſpirit, when well rectified, a flavour ſomewhat like that of French brandy, but this ſoon flies off; and the better method is to add a proper quantity of Glauber's ſtrong ſpirit of nitre to the ſpirit in the ſtill. The liquor in this caſe comes over impregnated with it, and the acid being more intimately mixed, the flavour is retained. See SPIRITUS *nitri dulcis*.

MALT-*duſt*, or the duſt ſeparated from the *malt* in drying, &c. is eſteemed a warm, rich MANURE for barren ground.

MALTSTER, a perſon who makes or trades in *malt*.

MALTA, *knights of*, an order of military religious, who have borne various other names; as, Hoſpitalers of St. John of Jeruſalem, knights of St. John, knights of Rhodes, order of *Malta*, religion of *Malta*, &c.

About the year 1048, ſome Neapolitan merchants founded a church after the Latin rite at Jeruſalem, giving it the name of *Sanctæ Mariæ della Latina*. They alſo founded a monaſtery of religious after the order of St. Benner, for the reception of pilgrims; and afterwards an hoſpital near the monaſtery, to take care of the diſeaſed, under the direction of a maſter or rector, to be nominated by the abbot of Santa Maria della Latina. Beſides which, they alſo built a chapel in honour of St. John Baptiſt.

In 1099, Godfrey of Bulloign, having taken Jeruſalem, endowed this hoſpital with ſome demeſnes which he had in France; and others imitating his liberality, the revenues of the hoſpital became conſiderably augmented. Upon this, Gerhard Tom, their rector, in concert with the Hoſpitalers, reſolved to ſeparate from the abbot and religious of Santa Maria, and to form a diſtinct congregation, under the name and protection of St. John Baptiſt: and hence it was that they had the name of *Hoſpitalers, or Brothers of St. John of Jeruſalem*.

Pope Paſcal II. by a bull in the year 1113, confirmed the donations made to this hoſpital, which he ſettled under the protection of the holy ſee; ordering, that the rectors, after Gerhard's death, ſhould be choſen by the Hoſpitalers. Raymond de Puy, Gerhard's ſucceſſor, took the title of *maſter*; and he gave a rule to the Hoſpitalers, which was approved by Calixtus II. in 1120. Such was the firſt riſe of the order of *Malta*.

Their firſt grand-maſter, finding the revenues of the hoſpital vaſtly to exceed what was neceſſary for the entertainment of poor pilgrims, and diſeaſed perſons, reſolved to employ the ſurplus againſt the infidels; and with this view he offered himſelf to the king of Jeruſalem.

He divided his Hoſpitalers into three claſſes; the firſt conſiſted of nobles, whom he deſtined to the profeſſion of arms, for the defence of the faith, and the protection of pilgrims; the ſecond conſiſted of prieſts or chaplains, who were to ſay maſs; and the third of ſervitors, who were not noble, but were alſo appointed for the war. He alſo regulated the manner of admitting knights brothers; and had the whole confirmed in 1130, by pope Innocent II. who gave them for arms a white croſs in a field argent, which continues ſtill the ſtandard of this order.

After the loſs of Jeruſalem, they retired firſt to Margath, then to Acre, which they defended very vigorouſly in 1290. After the entire loſs of the Holy Land, they withdrew to Cyprus, where king Henry of Luſignan, whom they had followed thither, gave them the city of Limiſſon. Here they continued eighteen years, when, taking the iſland of Rhodes from the Saracens in 1308, they ſettled there. And now it was that they firſt took the name of knights, *viz. the knights of Rhodes*.

Andronicus, emperor of Conſtantinople, granted to their grand maſter, Fulk de Villaret, the inveſtiture of this order; and the donation was confirmed by pope Clement. The year following, with the aſſiſtance of Amadeus IV. duke of Savoy, they defended themſelves, and their iſland, againſt an army of Saracens. In 1480, their grand-maſter d'Aubuſſon made a vigorous defence againſt Mahomet II. and preſerved the iſland, in ſpite of a formidable army, which beſieged it for the ſpace of three months. But, in 1522, it was attacked by Soliman with an army of three hundred thouſand men, and taken by him, after having been in the poſſeſſion of the knights two hundred and thirteen years.

After this loſs, the grand-maſter and knights retired firſt into the iſle of Candia. Some time after, pope Clement VII. gave them Viterbo. Laſtly, Charles V. in 1530, gave them the iſland of *Malta*, which they ſtill hold; and hence they come by the appellation of *knights of Malta*; though their proper name is that of *knights of the order of St. John of Jeruſalem*; and their grand-maſter, among his other titles, ſtill retains that of *maſter of the hoſpital of St. John, and guardian of the poor of our Saviour Jeſus Chriſt*.

The order of *Malta* have no other dominions beſides their iſland, and ſome other little places in the neighbourhood, the chief whereof are Goza and Comino.

The government is both monarchical and ariſtocratical, the grand-maſter being the ſovereign, and the chapter the ſenate. It is monarchical with regard to the inhabitants of *Malta*, and the iſles adjacent, and even with regard to the knights in every thing relating to the ſtatutes and rule of their order; and it is ariſtocratical with regard to the deciſion of any important affairs, which are not to be diſpatched, but by the grand-maſter and the chapter.

There are two councils; the one ordinary, compoſed of the grand-maſter as chief, and the grand-croſſes; the other complete, conſiſting of the grand-maſter, the grand-croſſes, and the two ſenior knights of each language.

By the languages of *Malta* are meant the ſeveral nations whereof the order is compoſed. Of theſe there are eight, viz. Provence, Auvergne, France, Italy, Arragon, Germany, Caſtile, and England.

The pillar (as he is called) of the language of Provence is the grand-commander of the order; he of Auvergne the grand marſhal; he of France the grand-hoſpitaller; he of Italy the grand-admiral; he of Arragon grand-conſervator, or draper, as he was anciently called; the pillar of the language of Germany is grand-bailiff; and he of Caſtile grand-chancellor: the language of England, which has been extinct ſince the time of the Reformation under king Henry VIII. had for its pillar or chief, the grand-turcopolier, or colonel of the cavalry. The language of Provence is the firſt, on account of Raimond de Puy, their firſt grand-maſter, who was a Provençal.

In each language there are ſeveral grand-priories, and

capital bailliages. To each language belongs a hall, where the knights eat, and hold their ordinary assemblies. Each grand-prior has a number of commanderies.

The commanderies are either magisterial, or else by right, or, finally, by favour. The magisterial are those annexed to the grand-masterſhip, whereof there is one in each grand-priory: commanderies by right are thoſe which come by right of ſeniority; their ſeniority is computed from the time of their admiſſion; but they muſt firſt have lived five years at *Malta*, and have made four caravanies, or cruiſing voyages, on the Turks and Corſairs: commanderies by favour are thoſe which the grand-maſter, or the grand-prior, have a right of conferring; one of theſe they confer every five years on whom they pleaſe. The noble knights are called knights by right; and none but theſe can be bailiffs, grand-priors, or grand-maſters. Knights by favour are thoſe, who, not being noble of themſelves, are raiſed on account of ſome great exploit, or ſome notable ſervice, into the rank of nobles.

The ſervitors, or ſerving-brothers, are of two kinds; 1. The ſervitors of war, whoſe functions are the ſame with thoſe of the knights. 2. The ſervitors of religion, whoſe whole buſineſs is to ſing the praiſes of God in the conventual church, and to aſſiſtate each in his turn as chaplain on board the veſſels and gallies of the order.

The brothers of obedience are prieſts, who, without being obliged to go to *Malta*, take the habit of the order, make the vows, and attach themſelves to the ſervice of ſome of the churches of the order, under the command of a grand-prior or commander, to whom they pay obedience.

The knights of minority are thoſe who, according to the ſtatutes, are admitted at ſixteen years of age. The knights of minority are thoſe who are admitted from the time of their birth; which, however, cannot be done, without a diſpenſation from the pope.

The chaplains can only be admitted regularly from ten to fifteen years of age: after fifteen, they muſt have a brief from the pope; till fifteen, the grand-maſter's letter is ſufficient. Theſe are called *diaconi*, and muſt give proof of their being born of creditable families.

For the proofs of nobility to be made before the admiſſion of knights, in the language of Germany, they go back ſix generations; in the reſt, it is ſufficient to go back to the great-grandfather on the father's or mother's ſide.

All the knights, after their profeſſion, are obliged to wear a white croſs, or ſtar with eight points, over the cloak or coat, on the left-ſide; which is the proper habit of the order, the golden croſs being only an ornament.

There are alſo female Hoſpitallers of the order of St John of Jeruſalem, ſometimes alſo called *chevaliereſſes*, or *knights*, of equal antiquity with the knights themſelves; whoſe buſineſs was to take care of the women-pilgrims, in an hoſpital apart from that of the men.

MALTA *earth*, in the *Materia Medica*. See MELITENSIS *terra*.

MALTHA, Μαλθα, in *Antiquity*, denotes any cement, or glutinous body, which has the faculty of binding things together.

Ancient writers make mention of divers ſorts of *maltha*, native and factitious: one of the latter much in uſe was compoſed of pitch, wax, plaiſter, and greaſe.

Another kind, wherewith the Romans plaiſtered and whitened the inſides of their aqueducts, was made of lime ſlacked in wine, incorporated with melted pitch, and freſh figs.

Natural *maltha* is a kind of bitumen, wherewith the Aſiatics plaiſter their walls. When this is once ſet on fire, water will not quench it; but ſerves rather to make it burn more fiercely.

MALTHA, the name of a voracious fiſh of the ſhark-kind, called the *ſerra*, and the *lamia* by ſome authors, a diminutive of *lamia*, ſignifying a ſmall ſhark. Its teeth are broad and pointed as thoſe of the ſhark; the fiſh has alſo many rows of theſe; the noſe is ſhort, and its fleſh lax and ſoft.

MALTHOCODE, a term by which the Greek writers expreſs the emollient topical remedies prepared with oil. Hippocrates expreſly forbids the uſe of theſe in old ulcers.

MALVA, in *Botany*. See MALLOW.

MALVINDA, *fides*, in *Botany*. See *Indian* MALLOW.

MALUS, in *Botany*. See APPLE-*Tree*.

MALUS *Aſſyria*, in *Botany*, one of the many names given by the ancients to the citron: they alſo called it *malus Medica*, and by ſeveral other names, as theſe were expreſſive of the country whence they had the fruit. See CITRON and CITREA *mensa*.

MAMALUKES, MAMMELUKES, or MAMMALUCKS, the name of a dynaſty, which reigned a conſiderable time in Egypt.

The word comes from מלך, *regere, imperare*, the Arabic participle whereof is ممليك *Mamlus*, which ſignifies *ſubject*, or one under the dominion of another. Scaliger holds, that the word is Arabic, and that it properly ſignifies ſomething bought with money; but others will have it ſignify any thing acquired, either as prize or purchaſe.

The *Mamalukes* were originally Turkiſh and Circaſſian ſlaves, bought of the Tartars by Meliſcaleb, to the number of a thouſand; whom he bred up to arms, and raiſed ſome to the principal offices of the empire. They killed ſultan Moadam in 1250, being affronted at his concluding a treaty with his priſoner St. Louis, without their privity. This Moadam was the laſt ſultan of the Ajoubites; to whom ſucceeded the *Mamalukes*, the firſt of whom was ſultan Azeddin, or Moux Ibec, the Tourcoman.

Others, ſay that the *Mamalukes* were ordinarily choſen from among the Chriſtian ſlaves; and that they were the ſame thing, in great meaſure, with the janizaries among the Turks. They never married. The firſt are ſaid to have been brought from Circaſſia; and ſome add that they firſt began to be talked of about the year 869.

MAMIRA, in the *Materia Medica of the Arabians*, a root frequently mentioned by Avicenna, Serapion, and other of the Arabian writers. It ſeems mentioned as a poiſonous drug, and is ſo deſcribed, that it ſeems to be the ſame with one ſpecies of the durunegi, or doronicum of the ſame authors, and the common doronicum of the ſhops, diſtinguiſhed from the antitheri, or other ſort of durunegi, by the yellowneſs of the inſide of the root. Avicenna ſays that it is hard and woody, and formed of knots or joints. This is the very deſcription the ſame author gives of the durunegi of the firſt or poiſonous kind. Paulus Ægineta ſays its root is compoſed of ſeveral joints alſo; and Alphagus calls it a *nodoſa* or jointed root. Some have ſuppoſed that the *mamira* was the ſame plant which we call ſmall celandine, but this has no title to be placed among the plants ſuſpected as poiſonous, nor any other pleas to be gueſſed at as the *mamira*, but only becauſe its roots conſiſt of many tubercles. Many things beſide have been conjectured to be the *mamira* of the Greeks and Arabians, but the DORONICUM ſeems to be the plant.

MAMMALIA, in *Natural Hiſtory*, the firſt claſs of animals in the Linnæan ſyſtem, divided into ſeven orders, viz. *primates, bruta, feræ, glires, pecora, belluæ*, and *cete*; comprehending forty genera, and two hundred and nineteen ſpecies.

MAMMÆ. See BREAST.

MAMMÆANÆ. See ALIMENTARY.

MAMMEE-*tree*, *mammea*, in *Botany*, a genus of the *polyandria monogynia* claſs. Its characters are theſe: the empalement of the flower is compoſed of two ſmall oval, concave leaves, which fall off; the flower has four large concave petals, which ſpread open; it hath many awl-ſhaped ſtamina, and in the centre a roundiſh germen, which afterwards turns to a fleſhy fruit of a ſpherical figure, incloſing one, two, or three large, almoſt oval ſtones: there is one ſpecies of this tree, which grows to a large ſize in the Weſt Indies, where the fruit is ſold in the markets: it has the taſte of a peach.

Ray mentions two ſpecies of this tree, and ſays that from inciſions made in the body of it, diſtils the liquor known by the name of toddy wine. Linnæus alſo mentions two ſpecies, one of which is the American and the other the Aſiatic *mammea*.

MAMMIFORM, MAMMIFORMIS, in *Anatomy*, a name given to two apophyſes of the bone in the back part of the ſkull; ſo called from their reſembling a breaſt.

MAMMILLARY, MAMMILLARIS, in *Anatomy*, an epithet given to two little protuberances, ſomewhat reſembling the nipples of the breaſt, found under the fore-ventricles of the brain, and ſuppoſed to be the organs of ſmelling. *See Tab. Anat. (Oſteol.) fig.* 7. *n.* 3. *fig.* 13. *lit.* d.

Theſe are called *apophyſes mammillares*.

There is alſo a muſcle called *mammillaris*, or *maſtoides*, ſerving to ſtoop the head.

MAMMOTH'S-*teeth*, or MAMMOUT *bones*, and MAMMON'S *horn*, in *Natural Hiſtory*, names given by travellers and other writers to certain foſſile teeth, and other bones, found in Ruſſia and ſome other parts of the world, and that uſually at great depths in the earth. The Ruſſians and other people give them this name, ſuppoſing them to have belonged to an animal which they deſcribe as being of a monſtrous ſize, and living in caverns under ground. But the true account of them is, that they are in reality the teeth and other bones of an animal now unknown, there being no ſuch beaſt as theſe people deſcribe. See ELEPHANT'S *Bones*, IVORY, &c.

MAN, *homo*, in *Zoology*, is ranked by Linnæus at the head of a claſs of animals, which he calls PRIMATES.

He diſtinguiſhes *men*, according to their colours; into the European, or white *men*; the American, or reddiſh-coloured *men*; the Aſiatic, or tawny-brown coloured *men*; and laſtly, thoſe of Africa, or the blacks. Linnæi,

Syſtem. Natur. tom. i. pars ii. p. 28, &c. Monſ. Buffon, among many other curious particulars, has given us ſeveral relating to the natural hiſtory of *man*. See Hiſtoire Naturelle, vol. iii. p. 305. edit. Paris. That ingenious author has entered into a conſiderable detail with reſpect to the varieties of the human ſpecies. See vol. iii. p. 371, ſeq. of the ſame work.

MAN *of the wood*. See ORANG-*Outang*.

MAN, in the *Materia Medica of the Ancients*, a name by which manna has been called by the oldeſt writers. There has been, however, ſome confuſion in the hiſtory of manna, owing to the too general uſe of this word, the ſame authors uſing it as the name of ſeveral other ſubſtances of very different kinds, which came to their hands in form of ſmall granules or flakes like the manna. The fragments of frankincenſe in particular were called by this name, with the addition of the word *thuris*, and ſometimes without, *man* or *men* ſtanding ſingly for that drug.

MAN, in *Mythology*, the name of a deity among the ancient Germans; whom they ſuppoſed to be the ſon of Tuiſton, and celebrated with ſongs, as the founder of their nation: and to him they conſecrated their groves and foreſts.

MAN *the capſton*, on board a *Ship*. See CAPSTAN.

MAN *the ſide, or ladder*, on board a *Ship*, is when an officer or any perſon of diſtinction is at the ſhip's ſide ready to come aboard, the men are commanded to wait, and help him up the ſide.

MAN *the top, or yard*, on board a *Ship*, a word of command for the men to go up to the top, or yard, for ſome particular ſervice.

MAN *of war*, the ſame with a ſhip of war. See SHIP and RATTE.

MAN-*bird*. See BIRDS *Anomalous*.

MANAA, in the *Jewiſh Cuſtoms*, a kind of offerings made in the temple, otherwiſe called MINCHA. The word *manaa* is uſed in the Septuagint.

MANACA, in *Botany*, a Braſilian baccifereous ſhrub, with an umbilicated *fruit*, like that of the juniper, containing three elliptical ſeeds, of the ſize of lentils; the part uſed in medicine is the root, which is great, ſolid and whitiſh; its medullary ſubſtance, reduced to powder, has very conſiderable effects; but becauſe it works too violently, both upwards and downwards, in the ſame manner as ſcammony, or the eſula, it is uſually given only to very robuſt perſons, and then with correctives, in a juſt dole; it has ſomewhat of a bitterneſs and acor. The root, macerated in water, makes a fomentation, or bath, for thoſe who are afflicted with wandering pains of the joints, eſpecially ſuch as are contracted by cold: the plant is uſed as a vulnerary by the Braſilians.

MANAGE, or MANEGE, an academy, or place for learning to ride the great horſe; as well as for breaking horſes to the proper motions and actions.

The word is borrowed from the French *manage*, and that from the Italian *maneggio*, or, ſome will have it, *a manu agendo*, from acting with the hand.

In every *manage* is a centre, or a place deſtined for vaulting round a pillar; a courſe or career for running the ring; and, on the ſide, are pillars, between which are placed the horſes intended for high airs.

MANAGE is alſo uſed for the exerciſe itſelf, either of the horſe, or the rider. See HORSEMANSHIP.

MANANAOG, in the *Materia Medica*, a name by which ſome call the fruit known with us by the name of St. Ignatius's bean.

MANATI, in *Zoology*. See SEA-*Cow*.

MANATI *lapis*, a name given to a bone, of which there are two found in the head of the *manati*, or ſea-cow; they are roundiſh and are uſually of the ſize of a hand-bell. They are ſaid to have great virtues againſt the ſtone and gravel, when burnt to aſhes, and given in white wine. The world need not, however, regret the ſcarcity of this remedy, for probably any animal bone, when burnt to aſhes, is poſſeſſed of all its virtues.

MANBALLA, in *Zoology*, the Ceyloneſe name of a ſpecies of ſerpent, called alſo the *canine*, or *dog ſerpent*, from its manner of flying at every thing that comes in its way, as our dogs do: it is of a deep brown colour, beautifully variegated with white.

MANBOTE, in our *Old Writers*, a compenſation or recompence for *homicide*, particularly due to the lord for killing his man or vaſſal.

MANCANILLA, in *Botany*, a name given by Plumier to a genus of plants, ſince characterized by Linnæus in the name of hippomane.

MANCHINEEL, *hippomane*, in *Botany*, a genus of the *monœcia monadelphia* claſs. Its characters are theſe: it hath male and female flowers on the ſame ſpike; the male flowers come out in ſmall cluſters, from a ſhort cup-ſhaped empalement, and have no petals: the female flowers have no petal, but an oval germen, which becomes a roundiſh fruit with a fleſhy cover, incloſing a rough hard ſhell with ſeveral cells; each including one ſeed: there are three ſpecies, natives of the Weſt Indies and of New Spain. Two of the ſpecies grow almoſt as large as the oak, but the third is of humbler ſize.

The wood of this tree is much eſteemed for cabinet work, being very durable, taking a fine poliſh, and as it is ſaid, not being eaten by worms; but the tree abounding with a milky cauſtic juice, before they are felled, they make fires round their trunks to burn out the juice; otherwiſe thoſe who fell them would be in danger of loſing their ſight, by this juice flying into their eyes: wherever this juice touches the ſkin, it raiſes bliſters; and if it falls upon linen, it turns it black, and waſhes into holes. The like danger to the eyes is to be apprehended from the ſaw-duſt; the workmen therefore generally cover their faces with a fine lawn.

This tree produces fruit ſomewhat like a golden pippin, which if ignorantly eaten, inflames the mouth and throat to a great degree; and is very dangerous to the ſtomach, unleſs remedies are timely applied. Miller.

Dr. Feyſſonnel, in his obſervations on this fruit, informs us that the ſavages uſe the juice of it to poiſon their arms, the wounds of which are thereby rendered mortal; that the rain which waſhes off the leaves, and falls on the human body, cauſes bliſters to riſe like boiling oil, and that even the ſhade of the tree is fatal to thoſe who ſit under it. However timely evacuation by purges and emetics, have prevented their ill effects. Phil. Tranſ. vol. l. art. 105. p. 772.

MANCIPLE, MANCEPS, in *Old Authors*, denotes a caterer. There was anciently an officer in the Temple called by this name: he is now called the ſteward; and both name and office are ſtill retained in the colleges in both univerſities.

MANCORON, a word uſed by the ancients to expreſs what they call a ſort of honey, which ſeems to have been evidently our modern SUGAR. They ſay that it was a ſort of dry honey found concreted in canes or reeds, and was of the conſiſtence of ſalt, and that it was found in India and Arabia Felix, and that when taken into the mouth, it broke under the teeth like ſalt.

MANCUS, formed of *manu cuſus*, in *Antiquity*, an Anglo-Saxon gold coin, equal in value to 25 ſolidi, or thirty-pence; and in weight to fifty-five Troy grains. The firſt account of this coin that occurs in the hiſtory of our country, is about the cloſe of the eighth century, in an embaſſy of Cenwulf, king of Mercia, to Leo III. requeſting the reſtoration of the juriſdiction of the ſee of Canterbury: this embaſſy was enforced by a preſent of one hundred and twenty *mancuſes*. Ethelwolf alſo ſent yearly to Rome three hundred *mancuſes*: and theſe coins are ſaid to have continued in ſome form or other, till towards the concluſion of the Saxon government. The heriots of the nobility are chiefly eſtimated by this ſtandard in Canute's laws. It came originally from Italy, where it was called *ducat*: and is ſuppoſed to have been the ſame with the drachma or miliarenſis, current in the Byzantine empire. Clarke on Coins, p. 280, &c. See MARK.

MANDAMUS, in *Law*, a writ iſſuing out of the court of king's-bench, ſent by the king, and directed to any perſon, corporation, or inferior court of judicature, within the king's dominions; requiring them to do ſome particular thing therein ſpecified, which pertains to their office and duty, and which the court of king's bench has previouſly determined, or, at leaſt, ſuppoſes to be conſonant to right and juſtice. This is a high prerogative writ, of a moſt extenſively remedial nature; and may be iſſued in ſome caſes, where the injured party has alſo a more tedious method of redreſs, as in the caſe of admiſſion or reſtitution to an office: but it iſſues in all caſes where the party hath a right to have any thing done, and hath no other ſpecific means of compelling its performance. A *mandamus*, therefore, lies to compel the admiſſion or reſtoration of the party applying to any office or franchiſe of a public nature, whether ſpiritual or temporal; to academical degrees; to the uſe of a meeting-houſe, &c. It lies for the production, inſpection, or delivery of public books and papers; for the ſurrender of the regalia of a corporation; to oblige bodies corporate to affix their common ſeal; to compel the holding of a court, &c. The writ of *mandamus* is made by ſtatute 9 Ann. cap. 20. a moſt full and effectual remedy for refuſal of admiſſion, where a perſon is intitled to an office or place in any corporation, and alſo for wrongful removal, when a perſon is legally poſſeſſed. It may alſo be iſſued, in purſuance of the ſtatute 2 Geo. I. cap. 4. in caſe within the regular time no election ſhall be made of the mayor or other chief officer, of any city, borough, or town corporate, or (being made) it ſhall afterwards become void; to require the electors to proceed to election, and proper courts to be held, for admitting and ſwearing in the magiſtrates ſo reſpectively choſen. This writ iſſues to the judges of any inferior court, commanding them to do juſtice according to the powers of their office, whenever

the

the ſame is delayed. For it is the peculiar buſineſs of the court of king's bench to ſuperintend all other inferior tribunals, and to grow in to inforce the due exerciſe of thoſe judicial or miniſterial powers, with which the crown or legiſlature hath inveſted them; and this, not only by reſtraining their exceſſes, but by quickening their negligence, and obviating their denial of juſtice. A *mandamus* may, therefore, be had to the courts of the city of London, to enter up judgment; to the ſpiritual courts to grant an adminiſtration, to ſwear a church-warden, and the like. This writ is founded on a ſuggeſtion, by the oath of the party injured, of his own right, and the denial of juſtice below; whereupon, in order more fully to ſatisfy the court that there is a probable ground for ſuch interpoſition, a rule is made (except in ſome general caſes, where the probable ground is manifeſt), directing the party complained of to ſhew cauſe why a writ of *mandamus* ſhould not iſſue: and if he ſhews no ſufficient cauſe, the writ itſelf is iſſued, at firſt in the alternative, to do this, or ſignify ſome reaſon to the contrary; to which a return or anſwer muſt be made, at a certain day. And if the inferior judge, or other perſon to whom the writ is directed, returns or ſignifies an inſufficient reaſon, then there iſſues in the ſecond place a peremptory *mandamus*, to do the thing abſolutely; to which no other return will be admitted, but a certificate of perfect obedience and due execution of the writ. If the inferior judge or other perſon make no return, or fails in his reſpect and obedience, he is puniſhable for his contempt by attachment. But if he, at the firſt, returns a ſufficient cauſe, although it ſhould be falſe in fact, the court of king's bench will not try the truth of the fact upon affidavits; but will for the preſent believe him, and proceed no farther on the *mandamus*. But then the party injured may have an action againſt him for his falſe return, and (if found falſe by the jury) ſhall recover damages equivalent to the injury ſuſtained; together with a peremptory *mandamus* to the defendant to do his duty. Blackſt. Com. book iii. p. 110, &c. and p. 264, &c.

MANDAMUS was alſo a charge to the ſheriff, to take into the king's hands all the lands and tenements of the king's widow, who, againſt her oath formerly given, married without the king's conſent.

MANDARIN, a name given by the Portugueſe to the nobility and magiſtracy of the eaſtern countries, eſpecially to thoſe of China.

The word *mandarin* is unknown in this ſenſe among the Chineſe, who, in lieu thereof, call their grandees and magiſtrates *quan*, or *quan fu*, q. d. ſervant or miniſter of a prince.

There are in China nine orders of *mandarins*, or nine degrees of nobility; which have as many different animals for their characteriſtics. The firſt is diſtinguiſhed by a crane, the ſecond by a lion, the third by an eagle, the fourth by a peacock, &c.

There are in all thirty-two or thirty-three thouſand *mandarins* in China. There are *mandarins* of letters, and *mandarins* of arms; both the one and the other of which paſs ſeveral examinations: beſides civil *mandarins*, or thoſe of juſtice.

Since the time that the Tartars have rendered themſelves maſters of China, moſt of the tribunals, or courts of juſtice, &c. inſtead of one *mandarin* for a preſident, have two; the one a Tartar, the other a Chineſe.

The *mandarinate* is not hereditary, nor are any raiſed to it but men of letters.

MANDARIN is alſo a name which the Chineſe give to the learned language of the country.

Beſides the proper and peculiar language of each nation and province, they have one common to all the learned men in the empire. This they call the *mandarin* tongue, or the language of the court. Their public officers, as notaries, lawyers, judges, and chief magiſtrates, write and ſpeak the *mandarin*.

MANDATARY, *mandatarius*, he to whom a command or charge is given: and he that comes to a benefice by a *mandamus* is called by this name.

MANDATE, MANDATUM, in the *Canon Law*, denotes a reſcript of the pope, by which he commands ſome ordinary, collator, or preſenter, to put the perſon there nominated in poſſeſſion of the firſt benefice vacant in his collation.

An apoſtolical *mandate* for the proviſion of benefices, is a monitorial and comminatory letter from the pope to a biſhop, by which he is injoined to provide a ſubſiſtence for thoſe who have been ordained by him, or his predeceſſors, from the tonſure to ſacred orders incluſively; and to allow them their ſubſiſtence till they be provided with a benefice. This practice was occaſioned by the biſhops formerly laying hands on great numbers, and afterwards abandoning them to miſery and want.

At firſt the popes only gave monitory *mandates*, which were no more than ſimple prayers and requeſts, that did not bind the ordinary; afterwards they gave preceptory *mandates*, which did not annul the proviſions of the ordinary; at laſt they ſet up executory *mandates*, by which the proviſions made by the ordinary, in prejudice of the *mandate*, were declared null; and the executor of the *mandate*, in default of the ordinary, conferred the benefice on the mandatory: but the pope's power in iſſuing theſe *mandates* is now very much reſtrained.

MANDIBULA, the JAW. See MAXILLÆ. Hence

MANDIBULARES, or *mandicatorii muſculi*. See MASSETER.

MANDIL, or MANDRIL, the name of a kind of cap or turban worn by the Perſians.

The *mandil* is formed by firſt wrapping round the head a piece of fine white linen five or ſix ells long; over this they wrap in the ſame manner, a piece of ſilk of the ſame length, and ſometimes of great value. To make the *mandil* genteel, care muſt be taken, that, in wrapping the ſilk, it be ſo managed, as that the ſeveral colours found in the ſeveral folds made a kind of waves, ſomewhat like what we ſee in marbled paper.

This dreſs is extremely majeſtic, but at the ſame time very heavy: it ſerves either as a ſhelter to the head from cold, or as a ſcreen from the exceſſive heat of the ſun; if is ſaid, that a blow of a cutlaſs will not penetrate it. In rainy weather they cover it with a kind of caſe or hood, made of red cloth.

The mode of the *mandil* has been for ſome time altered: during the time of Schah-Abbas II. it was round at top; in the time of Schah-Soliman, they brought one end of the ſilk out of the middle of the *mandil* over the head; and, laſtly, in the reign of Schah-Huſſein, the end of the ſilk, in lieu of its being gathered as before, was plaited in manner of a roſe; and this the Perſians account extremely graceful, and uſe it to this day.

MANDRAKE, *mandragora*, in *Botany*. Its characters are theſe: the empalement is bell-ſhaped, and of one leaf, cut at the top into five acute ſegments; the flower hath one erect, bell-ſhaped petal, which is a little larger than the empalement; and has five awl-ſhaped ſtamina, which are arched, and hairy at the baſe; in the centre is ſituated a roundiſh germen, which turns to a large round berry, with two cells, having a fleſhy receptacle convex on each ſide, filled with kidney-ſhaped ſeeds. We have but one ſpecies of this genus at preſent in the Engliſh gardens; which grows naturally in Spain, Portugal, Italy, and the Levant.

Mandrake has been recommended in caſe of barrenneſs, but without foundation. Its freſh root is a violent purge, the doſe being from ten grains to twenty in ſubſtance, and from half a dram to a dram in infuſion. It has been found to do ſervice in hyſteric complaints, but muſt be uſed with great caution, otherwiſe it will bring on convulſions, and many other very miſchievous ſymptoms. It has alſo a narcotic quality. At preſent we only uſe the freſh leaves in anodyne and emollient cataplaſms and fomentations.

Naturaliſts tell ſtrange ſtories of this plant; but, ſetting aſide its ſoporiferous virtue, the modern botaniſts will ſcarce warrant any of them, not even that human figure ordinarily aſcribed to its roots, eſpecially ſince the diſcovery of the artifice of charlatans in faſhioning it, to ſurpriſe the credulity of the people.

MANDRAGORAS, *Chineſe*, is the plant GINSENG.

MANDRAKE-*wine*, *mandragoritis vinum*, a ſort of medicinal impregnation of wine with the virtues of *mandrake* root. It is prepared by cutting into thin ſlices half a pound of the bark of *mandrake* roots, and ſtringing them on a thread, and letting them down into a veſſel containing nine gallons of white wine, ſo that they may hang looſely in it, and by that means fully impregnate it with their virtues. It was uſed in ſmall doſes as an anodyne and ſoporific. It had the ſame effects alſo, if only ſmelled to, and was ſometimes injected in cliſters to the ſame purpoſe. They ſay that half a pint of this liquor mixed with twelve times its quantity of wine, brings on a carus; and that even a ſmaller doſe than this, leſs diluted, is mortal.

MANDREL, a kind of wooden pulley, making a member of the turner's lathe.

Of theſe there are ſeveral kinds; as

MANDRELS, *flat*, which have three or more little pegs or points near the verge, and are uſed for turning flat boards on.

MANDRELS, *pin*, which have a long wooden ſhank to fit into a round hole made in the work to be turned.

MANDRELS, *hollow*, which are hollow of themſelves, and uſed for turning hollow work.

MANDRELS, *ſcrew*, for turning ſcrews, &c.

MANDRIL, in *Zoology*, a ſpecies of BABOON, or MONKEY.

MANDSJADE, in *Botany*, is an Indian ſiliquous or pod-bearing tree, with a ſpiked pentapetalous flower, and

long pods containing nodous scarlet-coloured beans; the tree is one of the tallest in the kingdom of Malabar, bears fruit the twentieth year after planting, and living near two hundred years.

The wood is of common use for various purposes, on account of its solidity; the leaves, reduced to powder, are used in the pagan religious rites; the seeds, which are not ungrateful to the taste, are eaten by the common people, either boiled whole, or ground to a meal; and are besides, of great use to goldsmiths and jewellers, who, on account of their exact equality, employ them instead of grains in weighing their wares; for each maijelins, as they call them, weighs four grains, such as are in use among the goldsmiths; who, also of the bruised seeds, moistened with water and borax, prepare a glue for conglutinating the finer sort of vessels, when broken. Of the bruised leaves the physicians prepare a potion for mitigating pains in the loins.

MANDUCATION, the action of *chewing*, otherwise called *mastication*.

Manducation is a term seldom used but in speaking of the eucharist. The catholics maintain a real *manducation* of the body of Christ; the reformed, on the contrary, take this *manducation* to be only figurative, and by faith. St. Augustine calls it *spiritual manducation*.

MANE-*short*, in the *Manege*, is a sort of covering for the upper part of a horse's head, and all round his neck, which at one end has two holes for the ears to pass through, and then joins to the halter upon the fore part of the head, and likewise to the surcingle, or long girth, upon the horse's back.

MANEGE. A horse is said to *manege* when he works upon volts and airs, which supposes him broke and bred. See MANAGE.

MANEGE *for a soldier's horse*, is a gallop of unequal swiftness, but so that the horse changes hands readily.

MANEGE, *high*, is the high or raised airs, which are proper for leaping horses. See AIRS.

MANEGED. A horse is said to be thoroughly *managed*, or a finished horse, that is well broken, bred, and confirmed in a particular air or manege, so as to bear well upon the hand, know the heels, and sit well upon the hips.

MANEQUIN, among *Painters*. See LAYMAN.

MANES, a poetical term, signifying the shades or ghosts of the deceased.

The heathens used a variety of ceremonies and sacrifices to appease the *manes* of those who were deprived of burial. See LEMURES and LEMURIA.

MANES, *dii*, were the same with *Inferi*, or the infernal gods, who tormented men; and to these the heathens offered sacrifices, to assuage their indignation.

The heathen theology is a little obscure with regard to these gods *manes*. Some hold, that they were the souls of the dead; others, that they were the genii of men; which last opinion suits best with the etymology of the word.

The heathens, it is pretty evident, used the word *manes* in several senses; so that it sometimes signified the ghosts of the departed, and sometimes the infernal or subterraneous deities, and in general all divinities that presided over tombs.

The evocation of the *manes* of the dead seems to have been very frequent among the Thessalians; but it was expressly prohibited by the Romans. See LARES.

MANGABEY, in *Zoology*, the white eye-lid MONKEY, described by Buffon, vol. xiv. p. 244, and Pennant, Brit. Zool. p. 114.

MANGANESE. See MAGNESIA.

MANGANUM, *Μάγγανον*, among the Greeks, a general name for instruments to throw large stones with.

MANGARATIA, in *Botany*, a name given by some authors to the plant of which the common ginger of the shops is the root.

MANGER, in a ship, a circular place made with planks fastened on the lower deck of a ship of war, right under the hawses, being about a foot and half in height; the use of which is to catch and receive the sea-water, beating in at the hawses in a storm of weather.

MANGO-*tree*, *mangifera*, in *Botany*, a genus of the *pentandria monogynia* class: the flower hath five petals, and the fruit is a kidney-shaped drupe; this is a vast tree, forty feet high, and eighteen in thickness, growing in the East Indies, where it spreads its numerous branches all around, at a great distance, being always green, and bearing fruit once or twice every year from six or seven years old to an hundred: it is propagated by incision, or sowing the seed, in Malabar, Goa, Bengal, Pegu, and many other countries of the East.

The fruit is of a roundish oblong figure, flat, slightly fluted, or hollowed at the sides, and shaped much like a sydney, bigger than a goose egg, smooth, shining, first green speckled with white, then inclining to yellow, and at the last of a gold colour; it has a yellowish and excellent pulp, not unlike that of a peach; or rather a plum, first acid, then acidulated, and pleasant to the taste; within the pulp is contained an oblong, compressed, and lanuginous stone, thin, yet very hard and tenacious, and including an oblong kernel, very like an almond, and of the same bigness, and of a bitterish though not unpleasant taste.

There are various sorts of this fruit, as there are of our apples and pears, which are very different, according to the countries where they grow: that species, which is without a stone, and is very grateful to the palate, seems to us only a variety or a degenerated fruit: the fruit is cut into slices, and eaten either without wine, or macerated in wine: it is also candied, in order to its preservation: sometimes they open it with a knife, and fill up the middle with fresh ginger, garlick, mustard, and salt, with oil or vinegar, that they may eat it with rice, or after the manner of pickled olives.

As to its temperament, this fruit is cold and moist, though the Indian physicians affirm the contrary. We make use of pickled mangoes which are imported to us, as we do of pickled cucumbers. The stones roasted are said to cure a looseness, which Garcias found to be true. The wood of the tree, with cinders is used for burning the carcases of the pagans, as being consecrated to this rite; whence it serves also for coffins, in which they deposit their dead; but it is but of a soft substance, and of a short duration. The stalks supply the place of areqna, or caunga, in the chewing of betel; the same calcined and reduced to powder, take away warts. Of the tender leaves, with the bark of the avanocoe, that is, the ricinus, the seed of cummin and parpaciagam, is made a decoction, which is highly beneficial in the cough, asthma, and other affections of the thorax. The bark of the tree pulverized, and taken in chicken broth, is an excellent dissolvent of extravasated and coagulated blood, occasioned by a fall, in any part of the body. The juice of the bark, with the white of an egg, and a very little opium, taken inwardly, is a present remedy against the diarrhœa, dysentery, and tenesmus. Of the gum of the tree, and the flowers of rice, with the addition of a small quantity of opium and pepper, are prepared pills, which also cure all sorts of fluxes of the belly. Of the flour of the dried kernels the natives have the art of preparing various kinds of food. James.

MANGOSTEEN, or MANGOSTAN, *garcinia*, in *Botany*, a genus of the *dodecandria monogynia* class. Its characters are these: the flower hath a three-leaved empalement, and four roundish petals, which are larger than the empalement; it has fifteen stamina, formed into a cylinder, and in the centre is situated an oval germen, crowned by a buckler-shaped plain stigma, divided into eight parts, which becomes a thick globular berry, with one cell, including eight hairy fleshy seeds, which are convex and angular. We know but one species, which grows naturally in the Molucca islands and New Spain. Miller. Linnæus enumerates two species.

The tree is large, and usually much branched; the leaves are six inches long, and two inches wide, of a lively green, and ornamented with a double series of ribs, one part of which makes a border that surrounds the whole verge of the leaves: the flower is small, and of a pale green colour; it is composed of four petals, which, when they open, shew the rudiments of the fruit forming itself within; these leaves do not fall off at all, but remain fastened to the bottom of the fruit till it is ripe, serving as a sort of support to it; the fruit grows to the bigness of an apple; it is perfectly round, and is covered with a hard and tough skin, which is of the twelfth of an inch thick, and is of a lively red, streaked with several yellow lines, which are so many filaments running along it; at the extremity there are placed several rays, which, running to the length of the tenth of an inch, meet together, and terminate in a point; the substance of the fruit is white, soft, and of a very agreeable taste, approaching to that of raspberries; the body of the fruit is composed of several lobes or quarters, as we call them, which will separate from one another like those of an orange; but they are not inclosed each in a separate skin as these are; there are in number the same with the rays at the end of the fruit, that is, there are seven of them. When the fruit is eaten before it is perfectly ripe, the whole is eaten together; but when it is thoroughly ripened, there is found a single kernel in the middle; this is greenish without and white within, and is of an insipid taste, and therefore usually thrown away. Mem. Acad. Scienc. Par. 1699.

This is an extremely agreeable fruit, and the eating it is never attended with any bad consequences, even though it be eaten in ever so large quantities. People who are

not used to the Indies are apt to give this the preference to all the fruits of the place; but the natives, and others who have accuſtomed themſelves to the ſmell of the *durio*, give that infinitely the preference. This is a large prickly fruit, of the ſize of a melon, of an intoxicating quality, and of a taſte like that of ſugar and cream, but with a ſmell like that of rotten onions. The ſmell is intolerable to ſtrangers, but cuſtom has made it familiar to the Indians, and they diſregard it. The peel or rind of the *mangouſtan* is a more powerful aſtringent than the pomegranate bark, and is given in decoction in diarrhœas and dyſenteries with great ſucceſs, as alſo in all other hæmorrhages. There is a ſort of wild *mangouſtan*, called by the Portugueſe *mato*, which grows in the woods both in the Eaſt Indies and in America. The fruit of this perfectly reſembles the true *mangouſtan*, but is not eatable.

MANGOUSTE, of Buffon, in *Zoology*. See ICHNEUMON.

MANGROVE, *rhizophora*, in *Botany*, a genus of the *dodecandria monogynia* claſs: the empalement and flower are each divided into four ſegments; and the ſeed, which is ſingle, is very long, and has a fleſhy baſe. Of this plant there are ſeveral ſpecies, which grow in ſalt water rivers, both in the Eaſt and Weſt Indies, where it is called *mangrove*, but as they will not grow upon land, it is needleſs to ſay more concerning them.

MANGROVE *grape*. See *Sea-ſide* GRAPE.

MANGROVE *tree*. See *Syrian* MALLOW.

MANHEB, a word uſed by ſome chemical writers to expreſs ſeorie of any kind.

MANIA, *madneſs*, in *Medicine*, the moſt violent and acute ſpecies of a delirium, ariſing from a perturbation of the imagination and judgment.

Signs of it. Theſe are a bold and reſolute aſpect, eyes ſuffuſed with blood, a tremulous motion of the eye lids, great pride diſcovering itſelf in the countenance, voice, and geſture, a grinding of the teeth, an uncommon hatred to particular perſons, little ſleep, a violent cephalalgia, a quickneſs of hearing, a ringing in the ears: but it is to be obſerved, as to the firſt-mentioned ſymptom, that thoſe perſons who have become *mad* through fear, have always in their aſpect a mixture of that terror the object firſt gave, and of that natural boldneſs which ariſes from *madneſs*. The patient often lays traps and ſnares for getting other people into his power, with intent to hurt them, though they never have injured him. Sometimes mad people have been known to murder others; and they always have ſo much ſtrength as to overpower almoſt any one perſon; and though they have no actual fever, yet they are inſenſible of the external cold, and in general of other pains or injuries; nay, they are ſo loſt in ſpeculation, as often ſcarce to feel the blows and laſhes they receive in the courſe of their cure. They often do not even hear the people who ſpeak to them, and are naturally of a very jocund and cheaſtful imagination, fancying themſelves kings and princes, and are delighted with muſic. They have a violent propenſity to venery, and ſuch an abſence of ſhame, that they will go to ſtool, or do any thing of a like kind, before any body. This is the uſual caſe in the height of the diſorder; and in its decline ſome are dull and ſtupid, others very ſorrowful and melancholy, and ſenſible of their unhappy diſorder.

The cauſe of the *mania* is thus accounted for by Quincy. As often as the ſpecies of things, wherewith we have been acquainted, are hurried together, we may be ſaid to dream; and thence in ſleep theſe ſpecies are added with other things, and variouſly compounded, from the manifold repercuſſions of the animal ſpirits, which ariſe from the cauſe producing ſleep, and preſſing the nerves, ſo as to revert the fluctuation of their juice. A delirium is therefore the dream of waking perſons, wherein ideas are excited without order or coherence, and the animal ſpirits are driven into irregular fluctuations.

If then the cauſe inducing a delirium be of that nature, that it can excite ideas or motions of a conſiderable impetus, without any regularity or order, ſuch a delirium will be attended with boldneſs or rage, and violent motions of the body; that is, a *mania* will be produced.

Now, it is plain, that all the known cauſes of this diſtemper give a greater diſpoſition to the blood for motion, and render it fluxile, but not conſiſtent, and uniformly thick enough; and therefore that they diſpoſe perſons likewiſe to continued fevers, ſince they occaſion the blood to be thrown out of the heart with an increaſed force, unleſs ſome other cauſe intervene, whereby the efficacies of theſe are interrupted in diſpoſing the blood into febrile motions; and the blood is ſo diſpoſed, as often as it can be rarefied into its minuteſt parts; that is ſo uniformly rarefied, that it can eaſily, with any force by the motion received from the heart, go into parts divifible at the occurſions of thoſe orifices, into which it ought to be diſtributed: for then the cohesion of the parts, which can be but very ſmall, will not be any obſtruction to the increaſe and propagation of the blood's velocity. But if it happen that the efficient cauſe, or the heart, throws the blood with a greater force, or that the blood can be more eaſily propelled in any given time, it will occaſion, at the ſame time, that ſome parts of the blood will be more nearly united, ſo as to form moleculæ, conſiſting of cohering particles; which moleculæ will cohere to one another, and not ſo eaſily obey the direction of the heart's propelling force. The blood hereupon cannot be uniformly rarefied, nor enter ſo eaſily into the ſmall orifices of the veſſels, and ſo ſoon travel through them: and therefore there will no fever ariſe, but a delirium without a fever, wherein the heat of the blood will be greater, and the preſſure in the brain uncertain: whence inconſtant recurſions of the ſpirits, inordinate undulations, confuſed vibrations of the nerves, and a remarkable energy of imagination; whence will proceed audacity and paſſion beyond meaſure. It is a diſeaſe very hard to cure, and is generally found to baffle the phyſician.

From diſſection of thoſe who died mad or melancholy, it appears that a congeſtion of blood or other fluids, in the veſſels of the brain, is a principal cauſe of theſe diſorders: or it may ariſe from ſuch an impreſs on ſome part of this organ of ſenſe, as excites the preternatural ſenſations which more particularly work on the imagination. Dr. Battie in his Treatiſe on *Madneſs*, having determined it to be a deluded imagination, ariſing from a preternatural ſtate or diſorder of ſenſation, the ſeat of which ſenſation he fixes in the nervous or medullary ſubſtance, derived from, or rather communicating with the brain, and the cauſe of it a preſſure upon the medullary ſubſtance contained in the nervous filaments, diſtinguiſhes *madneſs* into two ſpecies; one called *original*, which he aſcribes to an internal diſorder of the nervous ſubſtance, and the other *conſequential*, ariſing from a diſorder of the ſame nervous ſubſtance *ab extra*. The former may be known or reaſonably ſuſpected, when it neither follows nor accompanies any accident, which may be juſtly termed its external or remoter cauſe; when there is room to believe it hereditary, and when it both ceaſes and appears afreſh, without any imaginable cauſe: under all which circumſtances, he concludes it to be irremediable by medicine. Conſequential *madneſs* ſometimes admits of relief, though it frequently becomes habitual, and, in effect the ſame as *madneſs* ſtrictly original.

Though the brain, ſays Dr. Battie, is undoubtedly the principal ſeat of deluſive ſenſation, nevertheleſs it is not the only one; foraſmuch as the ſame ſanguinary or ſerous obſtructions are capable in any other part of the body of exciting falſe ideas, as well as *in the* brain, at leaſt to ſome degree, and in proportion to the quantity of medullary matter there collected, ſo as to be ſufficiently compreſſed by ſuch obſtructions. Thus the ſtomach, inteſtines, and uterus, are frequently the real ſeats of *madneſs*, occaſioned by the contents of theſe viſcera being ſtopped in ſuch a manner as to compreſs the many nervous filaments, which here communicate with one another by the meſenteric ganglia.

Perſons ſubject to it. Theſe are principally men of a choleric habit of body, and of violently paſſionate diſpoſitions. Thoſe who have continual domeſtic quarrels, are alſo frequently thrown into *madneſs* by it; and women frequently incur this diſeaſe from long ſuppreſſion of the menſes, and a habit of giving looſe to laſcivious thoughts. Suppreſſions of the hæmorrhoids, and of the evacuation of the ſemen, have ſometimes alſo driven men into *madneſs*; worms have alſo ſometimes occaſioned it, and ſometimes drunkenneſs.

Prognoſtics. Madneſs ariſing from immaterial cauſes, is much more difficult of cure than when it ariſes from diſorders of the bodily organs; hence when it ariſes from violent perturbations of the mind, or from intenſe ſtudy, it is almoſt incurable. When it ariſes from ſuppreſſions of the ſemen, or of the uterine or hæmorrhoidal diſcharges, there is great hope of a cure by proper means. But *mad* perſons in general, when they ſleep ſound, and always awake in outrageous fits, are to be eſteemed incurable, or at leaſt much more difficult of cure than others.

When *madneſs* proceeds from internal exoſtoſes of the cranium, or induration of the dura mater, it is incurable by art. Fracture, or impreſſion of the cranium, and conculſion of the head, have been ſometimes relieved. When inſolation is the cauſe, a free and early uſe of the lancet has been found uſeful. But if *madneſs* is the more immediate conſequence of the ſun's action upon the nervous ſubſtance, and if, however occaſioned, it is of conſiderable duration, it is very often incurable. From inflammation of thoſe membranes that ſurround the brain, *madneſs* is very dangerous, and frequently terminates in either apoplexy or mortification. When it is the conſequence of a chronical congeſtion of fluids, it frequently admits

admits of relief, if timely applied; and such congestion is less dangerous, and more easily removed, whenever the mesenteric nerves alone are affected. When produced by spasm, in consequence of the tumultuous passions of joy and anger, or by intoxicating drugs, and vinous spirits, it is generally very violent, and often fatal by its immediate effects; but if the patient is able to bear the first shock, this species of *madness* is much sooner relieved than the gradual and continual muscular constriction, occasioned by the more gentle passions of love, grief, or despair; or by long and uninterrupted attention to any one object, however pleasing. Laxity intervening between spasm and delirious pressure, whereby it becomes a remoter cause of *madness*, admits of cure, if duly applied; nor is it uncommon that the weakened membranes spontaneously recover their elastic tone, provided the spasmodic impulse is abated before their continuent fibres are distracted beyond their natural tendency to approximation. *Madness* consequent upon gluttony or idleness, easily submits to medicine, properly applied. If it is accompanied with other disorders, the prognostic is to be formed from those disorders; anxiety, like original *madness*, when it proceeds from a natural defect in the internal constitution of the nervous substance, is not radically curable: if it proceeds from any external cause, there is a prospect of better success. Insensibility or idiotism, arising from any constitutional imperfection, is pronounced incurable by physic; nor when it appears to be only the effect of consequential *madness*, has it been frequently known to be relieved by art or nature.

Method of Cure. A brisk purge is first to be given; after this the patient is to be blooded pretty freely, ten ounces at the least should be taken away; after this the senses are to be attempted to be roused by strong vomits. White hellebore was famous on this occasion among the ancients; and there are some cases in which it may be given with safety, and with great good effect. After this the violent emotion of the blood is to be attempearated by nitrous and absorbent medicines; and, after these, the several remedies usually esteemed specifics take place. Of this number are decoctions of the red anagallis or pimpernel, the ruta muraria, or white maidenhair, the several preparations of silver, the berries of the *herba Paris*, asses blood, and the like; and great care is to be taken to bring the haemorrhoidal and menstrual discharges as far as possible to regularity. In cases of retention of the semen, purified nitre is to be given in great quantities, and may be also externally used, applying it to the testes in a cataplasm. The use of opiates is scarce to be suffered in any delirium, but of all things is never to be given in *madness*, for it never gives them any sleep, but enrages and adds to the complaint, having the same effect that strong liquors would have upon them. The use of white hellebore, as a vomit, may be of great service in some cases; but in all hypochondriac complaints, and consequently in *madness*, in the causes of which these complaints have a share, it is certain to increase the disease. Junker.

We read of a *mania* arising from a callous pia mater. See Med. Ed. Edinb. vol. iv. art. 26.

Dr. Micheletti relates the cure of a young man, who, after being exposed to very hot weather at sea, and having committed violent debauches in drinking, became mad, without any fever. He was cured by violent bleeding, starving, weak very cold drink, the cold bath, and pouring cold water on his head. Hist. de l'Acad. des Scienc. 1734.

Madness, says Dr. Battie, considered as a delusive sensation, unconnected with any other symptom, requires the patient's being removed from all objects that act forcibly upon the nerves, and excite too lively a perception of things, more especially from such objects as are the known causes of his disorder. The visits, therefore, of affecting friends, as well as enemies, and the impertinent curiosity of those, who think it pastime to converse with madmen, and sport with their passions, ought strictly to be forbidden. On the same account, the place of confinement should be at some distance from home, and none of his own servants should be suffered to wait on him. Every unruly appetite should be checked; and every fixed imagination, if possible, diverted. The patient's body and place of residence should be kept clean; the air he breathes should be dry and free from noisome steams; his food easy of digestion, and simple, neither spirituous, nor high seasoned; and his amusement not too engaging, nor too long continued, but rendered agreeable by a well-timed variety; and his employment should be about such things as are indifferent, and which approach the nearest to an intermediate state, between pleasure and anxiety. In the cure of *madness*, supposed by Dr. Battie to arise from delirious pressure of the brain, or medullary substance in the nerves, he directs our first attention to lessen, divert, or dislodge the compressing matter from the part affected: the intentions for which purposes are depletion, revulsion, removal, and expression. When pressure of the brain and nerves is sudden, the two first intentions may be safely and effectually answered by the lancet and cupping glass, repeated in proportion to the strength of the patient and the greatness of the pressure. To the same purpose are recommended the neutral salts, such as nitre, sal catharticus amarus, magnesia alba, tartar, and all its preparations, but more especially the sal diureticus: this latter is also highly extolled by Dr. Muzzel, of Berlin, in his Treatise of Melancholy, who directs a dram to be given three times a-day in a draught of warm water, sweetened with honey: this with other moistened diet, the warm bath every night, and the flesh-brush every morning, bath, he says, great efficacy.

To promote revulsion, in particular, we are advised to the use of the oily and penetrating steams, arising from the skins and other soft parts of animals, newly slain; tepid fomentations and cataplasms, applied to the head, legs, and feet, and oily and emollient glysters. Sinapisms, caustics, errhines, and vesicatories, as also the rougher cathartics, emetics, and volatile diaphoretics, are liable to endanger farther constriction, and therefore, if employed at all, to be used with the utmost caution. In the case of phrenzies or sudden inflammations, Dr. Battie is suspicious of the cathartic salts, and even of nitre, if administered in too large doses. Delirious pressure, when gradual and chronical, in robust and plethoric habits, also indicates depletion and revulsion. But if the subject is naturally infirm, or exhausted by preceding illness, the lancet must be cautiously used, or entirely prohibited: these intentions being safely answered only by the mildest solutives, as the neutral salts, cassia, manna, &c. and the gums quickened with a few grains of aloes. Nevertheless, when the weakness of the patient does not contraindicate, if the stagnating matter refuses to submit to these gentle evacuants, though often and properly repeated, and more especially when the nervous substance contained in the abdomen is affected, the third and fourth intentions take place; and it becomes absolutely necessary to shake with violence the head and hypochondria, by convulsing the muscular fibres with emetics, rougher purges, and errhines. Dr. Battie observes, that though bleeding is in some cases serviceable and necessary, yet to a feeble or convulsed lunatic, the lancet is not less destructive than a sword. Blisters, caustics, and sharp purges, in short all painful applications, or pungent substances, are to be tried with great caution, or rather not to be tried at all in fits of fury. Nor does even defect of sensation allow their use, whenever such defect is occasioned by the preceding excess of the nervous energy, or when it is accompanied by spasm. For the same reason, the gums, and all the foetid anti-hysterics, though useful in *madness*, arising from, or complicated with some sort of spasmodic disorders, are condemned in all preternatural actions of the muscles; also in *madness* attended with a feverish heat, or which happens in a plethoric habit of body, or that follows an inflammatory obstruction of the brain. Opium, though approved by Dr. Battie for allaying the more tumultuous passions, and obtunding an excess of sensibility, is highly dangerous in that species of the disease which approaches to stupor and insensibility. Mineral waters, drank at the fountain-head, and bathing in the sea, or cold fresh water, though remedies that have been much depended on for the cure of *madness*, are contraindicated, whenever there is sufficient reason to suspect, that irresoluble congestions of the fluids clog the membranes contiguous to the nervous substance; or that the solids are strained beyond the possibility of recovering their natural elasticity. Dr. Battie also pronounces vomits to be not only improper, but mischievous, whenever there is a reasonable suspicion that the vessels of the brain or nervous integuments are so much clogged or strained as to endanger a rupture, or farther disunion, instead of a deliverance from their oppressive loads. He likewise urges the same objection against such muscular irritation, whenever the vessels are contracted with cold, or when their contents are rarefied with heat, and likewise in constitutions that are lax and feeble, and naturally spasmodic.

The anodyne medicines proper in this case, are camphor, camphor with nitre, musk, &c. and, after due evacuations, strong opiates may be used with advantage. If musk is given, the doses should consist of from ℈ i. to ʒ ß. Opium may be given to two grains. Camphor hath been given with great benefit, from ℈ i. to ʒ i. ß in a dose, and repeated every morning, and sometimes morning and night. Dr. Kennedy used to begin with an antimonial vomit, the next day he gave a large dose of camphor, and repeated it at night, and thus continued a few days; then in the day he gave pills of æthiops, gum guaiacum, &c. and at nights the camphor, till a cure was

was effected; in which he often soon succeeded. Dr. Mouro gives borax to ʒ ij. as a dose for procuring sleep. The emetics recommended in this disorder, are those of the antimonial kind; and the most effectual diuretics are alkaline salts in large doses. Dr. Mead observes, that in the cure of maniacs, evacuations by the kidneys are of greater consequence than is generally supposed; especially if the *mania* is of the furious kind, and accompanied with febrile heat. See LUNATIC, MADNESS, and MELANCHOLY.

MANICA, properly a sleeve. See HIPPOCRATES's *sleeve*. Hildanus calls by this name a particular sort of purse, open at both ends, which he describes in his Treatise de Gangræna & Sphacelo, and gives a figure thereof. This he directs to be put about a limb, just before the place of amputation, before the operation is performed.

MANICHEES, or MANICHEANS, MANICHEI, a sect of ancient heretics, who asserted two principles; so called from their author *Manes*, or *Manichæus*, a Persian by nation, and educated among the MAGI, being himself one of that number before he embraced Christianity.

This heresy had its first rise about the year 277, and spread itself principally in Arabia, Egypt, and Africa. St. Epiphanius, who treats of it at large, observes, that the true name of this heresiarch was Cubricus; and that he changed it for *Manes*, which in the Persian or Babylonish language signifies *wight*. A rich widow, whose servant he had been, dying without issue, left him store of wealth: after which he assumed the title of the apostle or envoy of Jesus Christ.

Manes was not contented with the quality of apostle of Jesus Christ, but he also assumed that of the Paraclete, whom Christ had promised to send: which Augustin explains, by saying, that *Manes* endeavoured to persuade men, that the Holy Ghost did personally dwell in him with full authority. He left several disciples, and among others, Addas, Thomas, and Hermas. These he sent, in his life-time, into several provinces to preach his doctrine. *Manes*, having undertaken to cure the king of Persia's son, and not succeeding, was put in prison upon the young prince's death; whence he made his escape; but he was apprehended soon after, and flayed alive.

However, the admiral writers, cited by D'Herbelot and Hyde, tell us, that *Manes*, after having been protected in a singular manner by Hormisdas, who succeeded Sapor in the Persian throne, but who was not able to defend him, at length, against the united hatred of the Christians, the Magi, the Jews, and the Pagans, was shut up in a strong castle, to serve him as a refuge against those who persecuted him on account of his doctrine. They add, that, after the death of Hormisdas, Varanes I. his successor, first protected *Manes*, but afterwards gave him up to the fury of the Magi, whose resentment against him was due to his having adopted the Sadducean principles, as some say; while others attribute it to his having mingled the tenets of the Magi, with the doctrines of Christianity. However it is certain that the *Manichæans* celebrated the day of their master's death. It has been a subject of much controversy, whether *Manes* was an impostor. The learned Dr. Lardner has examined the arguments on both sides; and though he does not choose to deny that he was an impostor, he does not discern evident proofs of it. He acknowledges that he was an arrogant philosopher, and a great schemist; but whether he was an impostor, he cannot certainly say. He was much too fond of philosophical notions, which he endeavoured to bring into religion, for which he is to be blamed: nevertheless, he observes, that every bold dogmatiser is not an impostor.

The doctrine of *Manes* was a motley mixture of the tenets of Christianity with the ancient philosophy of the Persians, in which he had been instructed during his youth. He combined these two systems, and applied and accommodated to Jesus Christ, the characters and actions which the Persians attributed to the god Mithras.

He established two principles, viz. a good and an evil one: the first, a most pure and subtile matter, which he called *light*, did nothing but good: and the second, a gross and corrupt substance, which he called *darkness*, nothing but evil. This philosophy is very ancient; and Plutarch treats of it at large in his Isis and Osiris.

Our souls, according to *Manes*, were made by the good principle, and our bodies by the evil one; those two principles being, according to him, coeternal, and independent of each other. Each of these is subject to the dominion of a superintending being, whose existence is from all eternity. The being who presides over the *light* is called God; he that rules the land of *darkness* bears the title of hyle or demon. The ruler of the *light* is supremely happy, and in consequence thereof, benevolent and good: the prince of *darkness* is unhappy in himself, and desirous of rendering others partakers of his misery, and is evil and malignant. These two beings have produced an immense multitude of creatures, resembling themselves, and distributed them through their respective provinces. After a contest between the ruler of *light* and the prince of *darkness*, in which the latter was defeated, this prince of *darkness* produced the first parents of the human race. The beings, engendered from this original stock, consist of a body formed out of the corrupt matter of the kingdom of *darkness*, and of two souls, one of which is sensitive and sinful, and owes its existence to the evil principle; the other rational and immortal, a particle of that divine *light*, which had been carried away in the contest, by the army of *darkness*, and immersed into the mass of malignant matter. The earth was created by God, out of this corrupt mass of matter, in order to be a dwelling for the human race, that their captive souls might, by degrees, be delivered from their corporeal prisons, and the celestial elements extended from the gross substance in which they were involved. With this view God produced two beings from his own substance, viz. Christ, and the Holy Ghost: for the *Manichæans* held a consubstantial Trinity. Christ, or the glorious intelligence, called by the Persians Mithras, subsisting in and by himself, and residing in the sun, appeared in due time among the Jews, clothed with the shadowy form of a human body, to disengage the rational soul from the corrupt body, and to conquer the violence of malignant matter. The Jews, incited by the prince of *darkness*, put him to an ignominious death, which he suffered not in reality, but only in appearance, and according to the opinion of men. When the purposes of Christ were accomplished, he returned to his throne in the sun, appointing apostles to propagate his religion, and leaving his followers the promise of the Paraclete or Comforter, who is *Manes*, the Persian. Those souls, who believe Jesus Christ to be the son of God, renounce the worship of the god of the Jews, who is the prince of *darkness*, and obey the laws delivered by Christ, and illustrated by *Manes*, the comforter, are gradually purified from the contagion of matter; and their purification being completed, after having passed through two states of trial, by water and fire, first in the moon, and then in the sun, their bodies return to their original mass; for the *Manichæans* derided the resurrection of bodies; and their souls ascend to the regions of *light*. But the souls of those, who have neglected the salutary work of purification, pass, after death, into the bodies of other animals, or natures, where they remain till they have accomplished their probation. Some, however, more perverse and obstinate, are consigned to a severer course of trial, being delivered over, for a time, to the power of malignant aerial spirits, who torment them in various ways. After this, a fire shall break forth and consume the frame of the world; and the prince and powers of *darkness*, shall return to their primitive bears of anguish and misery, in which they shall dwell for ever. These mansions shall be surrounded by an invincible guard, to prevent their ever renewing a war in the regions of *light*.

Manes borrowed many things from the ancient Gnostics; on which account, many authors consider the *Manichæans* as a branch of the Gnostics.

In truth, the *Manichæan* doctrine was a system of philosophy rather than of religion. They made use of amulets, in imitation of the Basilidians; and are said to have made profession of astronomy and astrology. They denied that Jesus Christ, who was only God, assumed a true human body, and maintained it was only imaginary: and, therefore, they denied his incarnation, death, &c. They pretended that the law of Moses did not come from God, or the good principle, but from the evil one; and that for this reason it was abrogated. They rejected almost all the sacred books, in which Christians book for the sublime truths of their holy religion. They affirmed, that the Old Testament was not the work of God, but of the prince of *darkness*, who was substituted by the Jews in the place of the true God. They abstained entirely from eating the flesh of any animal; following herein the doctrine of the ancient Pythagoreans: they also condemned marriage. The rest of their errors may be seen in St. Epiphanius and St. Augustin; which last, having been of their sect, may be presumed to have been thoroughly acquainted with them.

Though the *Manichees* professed to receive the books of the New Testament, yet, in effect, they only took so much of them as suited with their own opinions. They first formed to themselves a certain idea or scheme of Christianity; and to this adjusted the writings of the apostles; pretending that whatever was inconsistent with this, had been foisted into the New Testament by later writers, who were half Jews. On the other hand, they made fables and apocryphal books pass for apostolical writings; and even are suspected to have forged several

others, the better to maintain their errors. St. Epiphanius gives a catalogue of several pieces published by *Manes*, and adds extracts out of some of them. These are the Mysteries, Chapters, Gospel, and Treasury.

The rule of life and manners which *Manes* prescribed to his followers, was most extravagantly rigorous and severe. However, he divided his disciples into two classes; one of which comprehended the perfect Christians, under the name of the *elect*; and the other, the imperfect and feeble, under the title of *auditors* or *hearers*. The *elect* were obliged to a rigorous and entire abstinence from flesh, eggs, milk, fish, wine, all intoxicating drink, wedlock, and all amorous gratifications; and to live in a state of the severest penury, nourishing their emaciated bodies with bread, herbs, pulse, and melons, and depriving themselves of all the comforts that arise from the moderate indulgence of natural passions, and also from a variety of innocent and agreeable pursuits. The *auditors* were allowed to possess houses, lands, and wealth, to feed on flesh, to enter into the bonds of conjugal tenderness; but this liberty was granted them with many limitations, and under the strictest conditions of moderation and temperance. The general assembly of the *Manichæans* was headed by a president, who represented Jesus Christ. There were joined to him twelve rulers or masters, who were designed to represent the twelve apostles, and these were followed by seventy-two bishops, the images of the seventy-two disciples of our Lord. These bishops had presbyters or deacons under them, and all the members of these religious orders were chosen out of the class of the elect. Their worship was simple and plain; and consisted of prayers, reading the scriptures and hearing public discourses, at which both the auditors and elect were allowed to be present. They also observed the Christian appointments of baptism and the eucharist. They kept the Lord's day, observing it as a fast; and they likewise kept Easter and Pentecost.

Towards the fourth century, the *Manichæans* concealed themselves under various names, which they successively adopted, and changed in proportion as they were discovered by them. Thus they assumed the names of Encratites, Aporactics, Saccophori, Hydroparastatæ, Solitaries, and several others, under which they lay concealed for a certain time, but could not however long escape the vigilance of their enemies. About the close of the fifth century, this sect gained a very considerable influence, particularly among the Persians.

Toward the middle of the twelfth century the sect of *Manichees* took a new face, on occasion of one Constantine, an Armenian, and an adherer to it; who took upon him to suppress the reading of all other books besides the Evangelists, and the Epistles of St. Paul, which he explained in such manner, as to make them contain a new system of *Manicheism*. He entirely discarded all the writings of his predecessors; rejecting the chimæras of the Valentinians, and their thirty æons; the fable of *Manes*, with regard to the origin of rain, and other dreams; but still retained the impurities of Basilides. In this manner he reformed *Manicheism*, insomuch that his followers made no scruple of anathematizing Scythian, Buddas, called also Addas, and Terebinth, the contemporaries and disciples, as some say, and according to others, the predecessors and masters of *Manes*, and even *Manes* himself, Constantine being now their great apostle. After he had seduced an infinite number of people, he was at last stoned by order of the emperor.

This sect prevailed in Bosnia and the adjacent provinces, about the close of the fifteenth century; propagated their doctrines with confidence, and held their religious assemblies with impunity. See on the subject of this article, Mosheim's Eccl. Hist. vol. i. p. 239, &c. 8vo. edit. Lardner's Cred. of the Gospel Hist. vol. viii. passim, and Bayle, art. *Manichees*.

MANICORDION, a musical instrument, in form of a spinet.

Du-Cange derives the word from *manichord*, on a supposition this instrument has but one chord: but he is mistaken; it has fifty, or more.

Its strings are covered with pieces of scarlet cloth, to deaden, as well as soften, the sound; whence it is also called the *dumb spinet*, and is much used in nunneries for the religious to learn to play on; so as not to disturb the silence of the dormitory. Scaliger makes the *manicord* more ancient than the spinet or harpsichord.

MANICOU, in *Zoology*. See OPOSSUM.

MANICUM *strychnum*, in *Botany*, a term used by the old Greek writers to express a kind of nightshade, which, when taken internally, caused madness. Pliny, describing this species, says, that it has leaves like the ocymum or basil; and Theophrastus and Dioscorides say it had leaves like the cruca or rocket. Where Pliny had his information is not easy to guess, for he commonly copies from these authors: they are, however, much more to be depended on; and as the leaves of the ocymum or basil are not at all like those of the rocket, Pliny is certainly wrong in his account; and the most probable reason for his error is, that he mistook the Greek name of the plant, to which these authors compared the leaves of the *manicum strychnum*, and translated ocymum, which is the name of the rocket, into ocymum, basil; a name somewhat like the Greek one in sound, but wholly different in signification; the two plants basil and rocket not only having leaves very unlike one another, but being also of different genera. A yet greater error of Pliny, in regard to this plant, is his placing it among the excellent garden herbs, and saying that it was in use as a food, immediately after he had told us of its causing madness in those who eat it. This is an evident confusion of the manicum solanum with the pomum amoris or love apple, the fruit of which is eaten in soups at this time.

MANIFESTO, an apology, or public declaration in writing, made by a prince, shewing his intentions in any enterprize, the motives that induced him to it, and the reasons on which his right and pretensions are founded.

MANIFESTUS *clitoridis*, in *Anatomy*, a name given by Vesalius and others to one of the muscles of the female pudenda, called by Verheyhen simply the *musculus clitoridis*, but by Albinus and Cowper, *erector clitoridis*. Verheyhen is not to be censured for calling it only the *musculus clitoridis*, for it is properly the only muscle of that part, the other generally attributed to the clitoris, and called by Riolan and others, *clitoridis inferior* and *latus*, not properly belonging to that part, but being truly a sphincter vaginæ, or, as Albinus calls it, the *constrictor vaginæ*. See SPHINCTER.

MANIHOT, in *Botany*. See CASSADA.

MANILLE, or MENILLE, in *Commerce*, one of the principal commodities carried by the Europeans to the coasts of Africa, to traffick with the Negroes in exchange for slaves. It is a large brass ring in form of a bracelet, either flat or round, plain or engraven; with which the natives used to deck themselves, putting them on the small of the leg, and the thick of the arm above the elbow.

The better sort among the Negroes wear silver and gold *manilles*; but these are of their own manufacture; most of the money they receive for their other merchandizes being melted into *manilles*.

MANIPULATION, a term used in the mines, to signify the manner of digging the SILVER, &c. out of the earth.

MANIPULUS, MANIPULE, among the Romans, was a little body of infantry, which, in the time of Romulus, consisted of a hundred men; and in the time of the consuls, and first Cæsars, of two hundred.

The word properly signifies a handful; and, according to some authors, was first given to the handful of hay which they bore at the end of a pole, to distinguish themselves by, before the custom was introduced of bearing an eagle for their ensign; and hence also the phrase, a handful of men. But Vegetius, Modestus, and Varro, gave other etymologies of the word: the last derives it from *manus*, a little body of men following the same standard. According to the former, this corps was called *manipulus*, because they fought hand in hand, or all together: *Cuniherentium autem manipulus vocabatur ab eo, quod conjunctis manibus pariter dimicabant.*

Each *manipule* had two centurions, or captains, called *manipularii*, to command it; one whereof was lieutenant to the other. Each cohort was divided into three *manipules*, and each *manipule* into two centuries.

Aulus Gellius quotes an old author, one Cincius, who lived in the time of Hannibal (whose prisoner he was), and who, writing on the art of war, observes, that then each legion consisted of sixty centuries, of thirty *manipules*, and of ten cohorts. And again, Varro and Vegetius mention it as the least division in the army, only consisting of the tenth part of a century; and Spartian adds, that it contained no more than ten men. This shews, that the *manipulus* was not always the same thing. See LEGION.

MANIPULUS is also an ecclesiastical ornament, worn by the priests, deacons, and subdeacons, in the Romish church. It consists of a little fillet in form of a stole, three or four inches broad, and made of the same stuff with the chasuble; signifying and representing an handkerchief, which the priests in the primitive church wore on the arm, to wipe off the tears they were continually shedding for the sins of the people. There still remains a mark of this usage in a prayer rehearsed by those who wear it, *Meream, Domine, portare manipulum fletus & doloris.*

The Greeks and Maronites wear two *manipules*, one on each arm.

MANIPULUS, in *Physic*, denotes a measure, or fixed quan-

was effected; in which he often soon succeeded. Dr. Monro gives borax to 3 ij. as a dose for procuring sleep. The emetics recommended in this disorder, are those of the antimonial kind; and the most effectual diuretics are alkaline salts in large doses. Dr. Mead observes, that in the cure of maniacs, evacuations by the kidneys are of greater consequence than is generally supposed; especially if the mania is of the furious kind, and accompanied with febrile heat. See LUNATIC, MADNESS, and MELANCHOLY.

MANICA, properly a sleeve. See HIPPOCRATES's *sleeve*. Hildanus calls by this name a particular sort of purse, open at both ends, which he describes in his Treatise de Gangræna & Sphacelo, and gives a figure thereof. This he directs to be put about a limb, just before the place of amputation, before the operation is performed.

MANICHEES, or MANICHEANS, MANICHÆI, a sect of ancient heretics, who asserted two principles; so called from their author *Manes*, or *Manichæus*, a Persian by nation, and educated among the MAGI, being himself one of that number before he embraced Christianity.

This heresy had its first rise about the year 277, and spread itself principally in Arabia, Egypt, and Africa. St. Epiphanius, who treats of it at large, observes, that the true name of this heresiarch was Cubricus; and that he changed it for *Manes*, which in the Persian or Babylonish language signifies *light*. A rich widow, whose servant he had been, dying without issue, left him store of wealth: after which he assumed the title of the apostle or envoy of Jesus Christ.

Manes was not contented with the quality of apostle of Jesus Christ, but he also assumed that of the Paraclete, whom Christ had promised to send: which Augustin explains, by saying, that *Manes* endeavoured to persuade men, that the Holy Ghost did personally dwell in him with full authority. He left several disciples, and, among others, Addas, Thomas, and Hermas. These he sent, in his life-time, into several provinces to preach his doctrine. *Manes*, having undertaken to cure the king of Persia's son, and not succeeding, was put in prison upon the young prince's death; whence he made his escape; but he was apprehended soon after, and flayed alive.

However, the oriental writers, cited by D'Herbelot and Hyde, tell us, that *Manes*, after having been protected in a singular manner by Hormisdas, who succeeded Sapor in the Persian throne, but who was not able to defend him, at length, against the united hatred of the Christians, the Magi, the Jews, and the Pagans, was shut up in a strong castle, to serve him as a refuge against those who persecuted him on account of his doctrine. They add, that, after the death of Hormisdas, Varanes I. his successor, first protected *Manes*; but afterwards gave him up to the fury of the Magi, whose resentment against him was due to his having adopted the Seduccean principles, as some say; while others attribute it to his having mingled the tenets of the Magi, with the doctrines of Christianity. However it is certain that the *Manichæans* celebrated the day of their master's death. It has been a subject of much controversy, whether *Manes* was an impostor. The learned Dr. Lardner has examined the arguments on both sides; and though he does not choose to deny that he was an impostor, he does not discern evident proofs of it. He acknowledges that he was an arrogant philosopher, and a great schemist; but whether he was an impostor, he cannot certainly say. He was much too fond of philosophical notions, which he endeavoured to bring into religion, for which he is to be blamed: nevertheless, he observes, that every bold dogmatist is not an impostor.

The doctrine of *Manes* was a motley mixture of the tenets of Christianity with the ancient philosophy of the Persians, in which he had been instructed during his youth. He combined these two systems, and applied and accommodated to Jesus Christ, the characters and actions which the Persians attributed to the god Mithras.

He established two principles, viz. a good and an evil one; the first, a most pure and subtile matter, which he called *light*, did nothing but good; and the second, a gross and corrupt substance, which he called *darkness*, nothing but evil. This philosophy is very ancient; and Plutarch treats of it at large in his Isis and Osiris.

Our souls, according to *Manes*, were made by the good principle, and our bodies by the evil one; those two principles being, according to him, coeternal and independent of each other. Each of these is subject to the dominion of a superintending being, whose existence is from all eternity. The being who presides over the *light* is called God; he that rules the land of *darkness* bears the title of hyle or demon. The ruler of the *light* is supremely happy, and in consequence thereof, benevolent and good: the prince of *darkness* is unhappy in himself, and desirous of rendering others partakers of his misery, and is evil and malignant. These two beings have produced an immense multitude of creatures, resembling themselves, and distributed them through their respective provinces. After a contest between the ruler of *light* and the prince of *darkness*, in which the latter was defeated, this prince of *darkness* produced the first parents of the human race. The beings, engendered from this original stock, consist of a body formed out of the corrupt matter of the kingdom of *darkness*, and of two souls, one of which is sensitive and lustful, and owes its existence to the evil principle; the other rational and immortal, a particle of that divine *light*, which had been carried away in the contest, by the army of *darkness*, and immersed into the mass of malignant matter. The earth was created by God, out of this corrupt mass of matter, in order to be a dwelling for the human race, that their captive souls might, by degrees, be delivered from their corporeal prisons, and the celestial elements extended from the gross substance in which they were involved. With this view God produced two beings from his own substance, viz. Christ, and the Holy Ghost: for the *Manichæans* held a consubstantial Trinity. Christ, or the glorious intelligence, called by the Persians Mithras, subsisting in and by himself, and residing in the sun, appeared in due time among the Jews, clothed with the shadowy form of a human body, to disengage the rational soul from the corrupt body, and to conquer the violence of malignant matter. The Jews, incited by the prince of *darkness*, put him to an ignominious death, which he suffered not in reality, but only in appearance, and according to the opinion of men. When the purposes of Christ were accomplished, he returned to his throne in the sun, appointing apostles to propagate his religion, and leaving his followers the promise of the Paraclete or Comforter, who is *Manes*, the Persian. Those souls, who believe Jesus Christ to be the son of God, renounce the worship of the god of the Jews, who is the prince of *darkness*, and obey the laws delivered by Christ, and illustrated by *Manes*, the comforter, are gradually purified from the contagion of matter; and their purification being completed, after having passed through two states of trial, by water and fire, first in the moon, and then in the sun, their bodies return to their original mass; for the *Manichæans* derided the resurrection of bodies; and their souls ascend to the regions of *light*. But the souls of those, who have neglected the salutary work of purification, pass, after death, into the bodies of other animals, or natures, where they remain till they have accomplished their probation. Some, however, more perverse and obdurate, are consigned to a severer course of trial, being delivered over, for a time, to the power of malignant aerial spirits, who torment them in various ways. After this, a fire shall break forth and consume the frame of the world: and the prince and powers of *darkness*, shall return to their primitive seats of anguish and misery, in which they shall dwell for ever. These mansions shall be surrounded by an invincible guard, to prevent their ever renewing a war in the regions of *light*.

Manes borrowed many things from the ancient Gnostics; on which account, many authors consider the *Manichæans* as a branch of the Gnostics.

In truth, the *Manichæan* doctrine was a system of philosophy rather than of religion. They made use of amulets, in imitation of the Basilidians; and are said to have made profession of astronomy and astrology. They denied that Jesus Christ, who was only God, assumed a true human body, and maintained it was only imaginary: and, therefore, they denied his incarnation, death, &c. They pretended that the law of Moses did not come from God, or the good principle, but from the evil one; and that for this reason it was abrogated. They rejected almost all the sacred books, in which Christians look for the sublime truths of their holy religion. They affirmed, that the Old Testament was not the work of God, but of the prince of *darkness*, who was substituted by the Jews in the place of the true God. They abstained entirely from eating the flesh of any animal; following herein the doctrine of the ancient Pythagoreans: they also condemned marriage. The rest of their errors may be seen in St. Epiphanius and St. Augustin; which last, having been of their sect, may be presumed to have been thoroughly acquainted with them.

Though the *Manichees* professed to receive the books of the New Testament, yet, in effect, they only took so much of them as suited with their own opinions. They first formed to themselves a certain idea of scheme of Christianity; and to this adjusted the writings of the apostles; pretending that whatever was inconsistent with this, had been foisted into the New Testament by later writers, who were half Jews. On the other hand, they made fables and apocryphal books pass for apostolical writings; and even are suspected to have forged several

others, the better to maintain their errors. St. Epiphanius gives a catalogue of several pieces published by *Manes*, and adds extracts out of some of them. These are the Mysteries, Chapters, Gospel, and Treasury.

The rule of life and manners which *Manes* prescribed to his followers, was most extravagantly rigorous and severe. However, he divided his disciples into two classes; one of which comprehended the perfect Christians, under the name of the *elect*; and the other, the imperfect and feeble, under the title of *auditors or hearers*. The *elect* were obliged to a rigorous and entire abstinence from flesh, eggs, milk, fish, wine, all intoxicating drink, wedlock, and all amorous gratifications; and to live in a state of the severest penury, nourishing their emaciated bodies with bread, herbs, pulse, and melons, and depriving themselves of all the comforts that arise from the moderate indulgence of natural passions, and also from a variety of innocent and agreeable pursuits. The *auditors* were allowed to possess houses, lands, and wealth, to feed on flesh, to enter into the bonds of conjugal tenderness; but this liberty was granted them with many limitations, and under the strictest conditions of moderation and temperance. The general assembly of the *Manichæans* was headed by a president, who represented Jesus Christ. There were joined to him twelve rulers or masters, who were designed to represent the twelve apostles, and these were followed by seventy-two bishops, the images of the seventy-two disciples of our Lord. These bishops had presbyters or deacons under them, and all the members of these religious orders were chosen out of the class of the elect. Their worship was simple and plain; and consisted of prayers, reading the scriptures and hearing public discourses, at which both the auditors and elect were allowed to be present. They also observed the Christian appointments of baptism and the eucharist. They kept the Lord's day, observing it as a fast; and they likewise kept Easter and Pentecost.

Towards the fourth century, the *Manichæans* concealed themselves under various names, which they successively adopted, and changed in proportion as they were discovered by them. Thus they assumed the names of Encratites, Apotactics, Saccophori, Hydroparastatæ, Solitaries, and several others, under which they lay concealed for a certain time, but could not however long escape the vigilance of their enemies. About the close of the sixth century, this sect gained a very considerable influence, particularly among the Persians.

Toward the middle of the twelfth century the sect of *Manichæi* took a new face, on occasion of one Constantine, an Armenian, and an adherer to it; who took upon him to suppress the reading of all other books besides the Evangelists, and the Epistles of St. Paul, which he explained in such manner, as to make them contain a new system of *Manichæism*. He entirely discarded all the writings of his predecessors; rejecting the chimæras of the Valentinians, and their thirty æons; the fable of *Manes*, with regard to the origin of rain, and other dreams; but still retained the impurities of Basilides. In this manner he reformed *Manichæism*, insomuch that his followers made no scruple of anathematizing Scythian, Buddas, called also Addas, and Terebinth, the contemporaries and disciples, as some say, and according to others, the predecessors and masters of *Manes*, and even *Manes* himself, Constantine being now their great apostle. After he had seduced an infinite number of people, he was at last stoned by order of the emperor.

This sect prevailed in Bosnia and the adjacent provinces, about the close of the fifteenth century; propagated their doctrines with confidence, and held their religious assemblies with impunity. See on the subject of this article, Mosheim's Eccl. Hist. vol. i. p. 239, &c. 8vo. edit. Lardner's Cred. of the Gospel Hist. vol. viii. passim, and Bayle, art. *Manichæus*.

MANICORDION, a musical instrument, in form of a spinet.

Du-Cange derives the word from *manochord*, on a supposition this instrument has but one chord: but he is mistaken; it has five, or more.

Its strings are covered with pieces of scarlet cloth, to deaden, as well as soften, the sound; whence it is also called the *dumb spinet*, and is much used in nunneries for the religious to learn to play on; so as not to disturb the silence of the dormitory. Scaliger makes the *manicord* more ancient than the spinet or harpsichord.

MANICOU, in *Zoology*. See OPOSSUM.

MANICUM *strychnon*, in *Botany*, a term used by the old Greek writers to express a kind of nightshade, which, when taken internally, caused madness. Pliny, describing this species, says, that it has leaves like the acyamum or basil; and Theophrastus and Dioscorides say it had leaves like the eruca or rocket. Where Pliny had his information is not easy to guess, for he commonly copies from these authors: they are, however, much more to be depended on; and as the leaves of the acyamum or basil are not at all like those of the rocket, Pliny is certainly wrong in his account; and the most probable reason for his error is, that he mistook the Greek name of the plant, to which their authors compared the leaves of the *manicum strychnon*, and translated *acyamum*, which is the name of the rocket, into *acyamum*, basil, a name somewhat like the Greek one in sound, but wholly different in signification; the two plants basil and rocket not only having leaves very unlike one another, but being also of different genera. A yet greater error of Pliny, in regard to this plant, is his placing it among the efculent garden herbs, and saying that it was in use as a food, immediately after he had told us of its deadly qualities in those who eat it. This is an evident confusion of the manicum solanum with the pomum amoris or love apple, the fruit of which is eaten in soups at this time.

MANIFESTO, an apology, or public declaration in writing, made by a prince, shewing his intentions in any enterprize, the motives that induced him to it, and the reasons on which his right and pretensions are founded.

MANIFESTUS *clavicula*, in *Anatomy*, a name given by Vesalius and others to one of the muscles of the female pudenda, called by Verheyhen simply the *musculus clitoridis*, but by Albinus and Cowper, *erector clitoridis*. Verheyhen is not to be censured for calling it only the *musculus clitoridis*, for it is properly the only muscle of that part, the other generally attributed to the clitoris, and called by Riolan and others, *clitoridis inferior* and *levator*, not properly belonging to that part, but being truly a sphincter vaginæ, or, as Albinus calls it, the *constrictor cunni*. See DEMISSUS.

MANIHOT, in *Botany*. See CASSADA.

MANILLE, or MANILLE, in *Commerce*, one of the principal commodities carried by the Europeans to the coasts of Africa, to traffick with the Negroes in exchange for slaves. It is a large brass ring in form of a bracelet, either flat or round, plain or engraven; with which the natives used to deck themselves, putting them on the small of the leg, and the thick of the arm above the elbow.

The better sort among the Negroes wear silver and gold *manilles*; but these are of their own manufacture; most of the money they receive for their other merchandizes being melted into *manilles*.

MANIPULATION, a term used in the mines, to signify the manner of digging the SILVER, &c. out of the earth.

MANIPULUS, MANIPLE, among the Romans, was a little body of infantry, which, in the time of Romulus, consisted of a hundred men; and in the time of the consuls, and first Cæsars, of two hundred.

The word properly signifies a handful; and, according to some authors, was first given to the handful of hay which they bore at the end of a pole, to distinguish themselves by, before the custom was introduced of bearing an eagle for their ensign: and hence also the phrase, a handful of men. But Vegetius, Modestus, and Varro, gave other etymologies of the word: the last derives it from *manus*, a little body of men following the same standard. According to the former, this corps was called *manipulus*, because they fought hand in hand, or all together: *Centuriorum autem manipulus vocabatur eo ex, quod conjunctis manibus pariter dimicarent.*

Each *manipule* had two centurions, or captains, called *manipularii*, to command it; one whereof was lieutenant to the other. Each cohort was divided into three *manipules*, and each *manipule* into two centuries.

Aulus Gellius quotes an old author, one Cincius, who lived in the time of Hannibal (whose prisoner he was), and who, writing on the art of war, observes, that then each legion consisted of sixty centuries, of thirty *manipules*, and of ten cohorts. And again, Varro and Vegetius mention it as the least division in the army, only consisting of the tenth part of a century: and Spartian adds, that it contained no more than ten men. This shews, that the *manipules* was not always the same thing. See LEGION.

MANIPULUS is also an ecclesiastical ornament, worn by the priests, deacons, and subdeacons, in the Romish church. It consists of a little fillet in form of a stole, three or four inches broad, and made of the same stuff with the chasuble; signifying and representing an handkerchief, which the priests in the primitive church wore on the arm, to wipe off the tears they were continually shedding for the sins of the people. There still remains a mark of this usage in a prayer rehearsed by those who wear it, *Merear, Domine, portare manipulum fletus & doloris*.

The Greeks and Maronites wear two *manipules*, one on each arm.

MANIPULUS, in *Physic*, denotes a measure, or fixed quan-

was effected; in which he often soon succeeded. Dr. Monro gives borax to 3 ij. as a dose for procuring sleep. The emetics recommended in this disorder, are those of the antimonial kind; and the most effectual diuretics are alkaline salts in large doses. Dr. Mead observes, that in the cure of maniacs, evacuations by the kidneys are of greater consequence than is generally supposed; especially if the *mania* is of the furious kind, and accompanied with febrile heat. See LUNATIC, MADNESS, and MELANCHOLY.

MANICA, properly a sleeve. See HIPPOCRATES's *sleeve*. Hildanus calls by this name a particular sort of purse, open at both ends, which he describes in his Treatise de Gangræna & Sphacelo, and gives a figure thereof. This he directs to be put about a limb, just before the place of amputation, before the operation is performed.

MANICHEES, or MANICHEANS, MANICHÆI, a sect of ancient heretics, who asserted two principles; so called from their author *Manes*, or *Manichæus*, a Persian by nation, and educated among the MAGI, being himself one of that number before he embraced Christianity.

This heresy had its first rise about the year 277, and spread itself principally in Arabia, Egypt, and Africa. St. Epiphanius, who treats of it at large, observes, that the true name of this heresiarch was Cubricus; and that he changed it for *Manes*, which in the Persian or Babylonish language signifies *wise*. A rich widow, whose servant he had been, dying without issue, left him store of wealth: after which he assumed the title of the apostle or envoy of Jesus Christ.

Manes was not contented with the quality of apostle of Jesus Christ, but he also assumed that of the Paraclete, whom Christ had promised to send: which Augustin explains, by saying, that *Manes* endeavored to persuade men, that the Holy Ghost did personally dwell in him with full authority. He left several disciples, and, among others, Addas, Thomas, and Hermas. These he sent, in his life-time, into several provinces to preach his doctrine. *Manes*, having undertaken to cure the king of Persia's son, and not succeeding, was put in prison upon the young prince's death; whence he made his escape; but he was apprehended soon after, and flayed alive.

However, the oriental writers, cited by D'Herbelot and Hyde, tell us, that *Manes*, after having been protected in a singular manner by Hormisdas, who succeeded Sapor in the Persian throne, but who was not able to defend him, at length, against the united hatred of the Christians, the Magi, the Jews, and the Pagans, was shut up in a strong castle, to serve him as a refuge against those who persecuted him on account of his doctrine. They add, that, after the death of Hormisdas, Varanes I. his successor, first protected *Manes*; but afterwards gave him up to the fury of the Magi, whose resentment against him was due to his having adopted the Sadducean principles, as some say; while others attribute it to his having mingled the tenets of the Magi, with the doctrines of Christianity. However it is certain that the *Manichæans* celebrated the day of their master's death. It has been a subject of much controversy, whether *Manes* was an impostor. The learned Dr. Lardner has examined the arguments on both sides; and though he does not choose to deny that he was an impostor, he does not discern evident proofs of it. He acknowledges that he was an arrogant philosopher, and a great schemist; but whether he was an impostor, he cannot certainly say. He was much too fond of philosophical notions, which he endeavoured to bring into religion, for which he is to be blamed: nevertheless, he observes, that every bold dogmatiser is not an impostor.

The doctrine of *Manes* was a motley mixture of the tenets of Christianity with the ancient philosophy of the Persians, in which he had been instructed during his youth. He combined these two systems, and applied and accommodated to Jesus Christ, the characters and actions which the Persians attributed to the god Mithras.

He established two principles, viz. a good and an evil one: the first, a most pure and subtile matter, which he called *light*, did nothing but good; and the second, a gross and corrupt substance, which he called *darkness*, nothing but evil. This philosophy is very ancient; and Plutarch treats of it at large in his Isis and Osiris.

Our souls, according to *Manes*, were made by the good principle, and our bodies by the evil one; those two principles being, according to him, coeternal, and independent of each other. Each of these is subject to the dominion of a superintending being, whose existence is from all eternity. The being who presides over the *light* is called God; he that rules the land of *darkness* bears the title of hyle or demon. The ruler of the *light* is supremely happy, and in consequence thereof, benevolent and good: the prince of *darkness* is unhappy in himself, and desirous of rendering others partakers of his misery, and is evil and malignant. These two beings have produced an immense multitude of creatures, resembling themselves, and distributed them through their respective provinces. After a contest between the ruler of *light* and the prince of *darkness*, in which the latter was defeated, this prince of *darkness* produced the first parents of the human race. The beings engendered from this original stock, consist of a body formed out of the corrupt matter of the kingdom of *darkness*, and of two souls, one of which is sensitive and lustful, and owes its existence to the evil principle; the other rational and immortal, a particle of that divine *light*, which had been carried away in the contest, by the army of *darkness*, and immersed into the mass of malignant matter. The earth was created by God, out of this corrupt mass of matter, in order to be a dwelling for the human race, that their captive souls might, by degrees, be delivered from their corporeal prisons, and the celestial elements extended from the gross substance in which they were involved. With this view God produced two beings from his own substance, viz. Christ, and the Holy Ghost: for the *Manichæans* held a consubstantial Trinity. Christ, or the glorious intelligence, called by the Persians Mithras, subsisting in and by himself, and residing in the sun, appeared in due time among the Jews, clothed with the shadowy form of a human body, to disengage the rational soul from the corrupt body, and to conquer the violence of malignant matter. The Jews, incited by the prince of *darkness*, put him to an ignominious death, which he suffered not in reality, but only in appearance, and according to the opinion of men. When the purposes of Christ were accomplished, he returned to his throne in the sun, appointing apostles to propagate his religion, and leaving his followers the promise of the Paraclete or Comforter, who is *Manes*, the Persian. Those souls, who believe Jesus Christ to be the son of God, renounce the worship of the god of the Jews, who is the prince of *darkness*, and obey the laws delivered by Christ, and illustrated by *Manes*, the comforter, are gradually purified from the contagion of matter; and their purification being completed, after having passed through two states of trial, by water and fire, first in the moon, and then in the sun, their bodies return to their original mass; for the *Manichæans* derided the resurrection of bodies; and their souls ascend to the regions of *light*. But the souls of those, who have neglected the salutary work of purification, pass, after death, into the bodies of other animals, or natures, where they remain till they have accomplished their probation. Some, however, more perverse and obstinate, are consigned to a severer course of trial, being delivered over, for a time, to the power of malignant aerial spirits, who torment them in various ways. After this, a fire shall break forth and consume the frame of the world: and the prince and powers of *darkness*, shall return to their primitive seats of anguish and misery, in which they shall dwell for ever. These mansions shall be surrounded by an invincible guard, to prevent their ever renewing a war in the regions of *light*.

Manes borrowed many things from the ancient Gnostics; on which account, many authors consider the *Manichæans* as a branch of the Gnostics.

In truth, the *Manichæan* doctrine was a system of philosophy rather than of religion. They made use of amulets, in imitation of the Basilidians; and are said to have made profession of astronomy and astrology. They denied that Jesus Christ, who was only God, assumed a true human body, and maintained it was only imaginary: and, therefore, they denied his incarnation, death, &c. They pretended that the law of Moses did not come from God, or the good principle, but from the evil one; and that for this reason it was abrogated. They rejected almost all the sacred books, in which Christians look for the sublime truths of their holy religion. They affirmed, that the Old Testament was not the work of God, but of the prince of *darkness*, who was substituted by the Jews in the place of the true God. They abstained entirely from eating the flesh of any animal; following herein the doctrine of the ancient Pythagoreans: they also condemned marriage. The rest of their errors may be seen in St. Epiphanius and St. Augustin; which last, having been of their sect, may be presumed to have been thoroughly acquainted with them.

Though the *Manichees* professed to receive the books of the New Testament, yet, in effect, they only took so much of them as suited with their own opinions. They first formed to themselves a certain idea or scheme of Christianity; and to this adjusted the writings of the apostles; pretending that whatever was inconsistent with this, had been foisted into the New Testament by later writers, who were half Jews. On the other hand, they made fables and apocryphal books pass for apostolical writings; and even are suspected to have forged several

others, the better to maintain their errors. St. Epiphanius gives a catalogue of several pieces publiſhed by *Manes*, and adds extracts out of ſome of them. Theſe are the Myſteries, Chapters, Goſpel, and Treaſury.

The rule of life and manners which *Manes* preſcribed to his followers, was moſt extravagantly rigorous and ſevere. However, he divided his diſciples into two claſſes; one of which comprehended the perfect Chriſtians, under the name of the *elect*; and the other, the imperfect and feeble, under the title of *auditors* or *hearers*. The *elect* were obliged to a rigorous and entire abſtinence from fleſh, eggs, milk, fiſh, wine, all intoxicating drink, weſtlock, and all amorous gratifications; and to live in a ſtate of the ſevereſt penury, nouriſhing their emaciated bodies with bread, herbs, pulſe, and melons, and depriving themſelves of all the comforts that ariſe from the moderate indulgence of natural paſſions, and alſo from a variety of innocent and agreeable purſuits. The *auditors* were allowed to poſſeſs houſes, lands, and wealth, to feed on fleſh, to enter into the bonds of conjugal tenderneſs; but this liberty was granted them with many limitations, and under the ſtricteſt conditions of moderation and temperance. The general aſſembly of the *Manichæans* was headed by a preſident, who repreſented Jeſus Chriſt. There were joined to him twelve rulers or maſters, who were deſigned to repreſent the twelve apoſtles, and theſe were followed by ſeventy-two biſhops, the images of the ſeventy-two diſciples of our Lord. Theſe biſhops had preſbyters or deacons under them, and all the members of theſe religious orders were choſen out of the claſs of the elect. Their worſhip was ſimple and plain; and conſiſted of prayers, reading the ſcriptures and hearing public diſcourſes, at which both the auditors and elect were allowed to be preſent. They alſo obſerved the Chriſtian appointments of baptiſm and the euchariſt. They kept the Lord's day, obſerving it as a faſt; and they likewiſe kept Eaſter and Penteco.

Towards the fourth century, the *Manichæans* concealed themſelves under various names, which they ſucceſſively adopted, and changed in proportion as they were diſcovered by them. Thus they aſſumed the names of Eorrites, Aporatics, Saccophori, Hydroparaſtatæ, Solitaries, and ſeveral others, under which they lay concealed for a certain time, but could not however long eſcape the vigilance of their enemies. About the cloſe of the ſixth century, this ſect gained a very conſiderable influence, particularly among the Perſians.

Toward the middle of the twelfth century the ſect of *Manichees* took a new face, on occaſion of one Conſtantine, an Armenian, and an adherer to it; who took upon him to ſuppreſs the reading of all other books beſides the Evangeliſts, and the Epiſtles of St. Paul, which he explained in ſuch manner, as to make them contain a new ſyſtem of *Manicheiſm*. He entirely diſcarded all the writings of his predeceſſors; rejecting the chimæras of the Valentinians, and their thirty æons; the fable of *Manes*, with regard to the origin of rain, and other dreams; but ſtill retained the impurities of Baſilides. In this manner he reformed *Manicheiſm*, inſomuch that his followers made no ſcruple of anathematizing Scythian, Buddas, called alſo Addas, and Terebinth, the contemporaries and diſciples, as ſome ſay, and according to others, the predeceſſors and maſters of *Manes*, and even *Manes* himſelf, Conſtantine being now their great apoſtle.

After he had ſeduced an infinite number of people, he was at laſt ſtoned by order of the emperor.

This ſect prevailed in Boſnia and the adjacent provinces, about the cloſe of the fifteenth century; propagated their doctrines with confidence, and held their religious aſſemblies with impunity. See on the ſubject of this article, Moſheim's Eccl. Hiſt. vol. i. p. 230, &c. 8vo. edit. Lardner's Cred. of the Goſpel Hiſt. vol. viii. paſſim, and Bayle, art. *Manichees*.

MANICORDION, a muſical inſtrument, in form of a ſpinet.

Du-Cange derives the word from *manichord*, on a ſuppoſition this inſtrument has but one chord: but he is miſtaken; it has fifty, or more.

Its ſtrings are covered with pieces of ſcarlet cloth, to deaden, as well as ſoften, the ſound; whence it is alſo called the *tomis ſpinnet*, and is much uſed in nunneries for the religious to learn to play on; ſo as not to diſturb the ſilence of the dormitory. Scaliger makes the *manichord* more ancient than the ſpinet or harpſichord.

MANICOU, in *Zoology*. See OPOSSUM.

MANICUM *Strychnum*, in *Botany*, a term uſed by the old Greek writers to expreſs a kind of nightſhade, which, when taken internally, cauſed madneſs. Pliny, deſcribing this ſpecies, ſays, that it has leaves like the cotyledon or baſil; and Theophraſtus and Dioſcorides ſay it has leaves like the eruca or rocket. Where Pliny had his information is not eaſy to gueſs, for he commonly copies from theſe authors: they are, however, much more to be depended on; and as the leaves of the cotyledon or baſil are not at all like thoſe of the rocket, Pliny is certainly wrong in his account; and the moſt probable reaſon for his error is, that he miſtook the Greek name of the plant, to which theſe authors compared the leaves of the *manicum ſtrychnum*, and tranſlated *cotyledon*, which is the name of the rocket, into *cotyledon*, both a name ſomewhat like the Greek one in ſound, but wholly different in ſignification; the two plants baſil and rocket not only having leaves very unlike one another, but being alſo of different powers. A yet greater error of Pliny, in regard to this plant, is his placing it among the eſculent garden herbs, and ſaying that it was in uſe as a food, immediately after he had ſold us of its cauſing madneſs in thoſe who eat it. This is an evident confuſion of the orantze balauſtin with the pomum amoris or love apple, the fruit of which is eaten in ſoups at this time.

MANIFESTO, an apology, or public declaration in writing, made by a prince, ſhewing his intentions in any enterpriſe, the motives that induced him to it, and the reaſons on which his right and pretenſions are founded.

MANIFESTUS *oſſiculi*, in *Anatomy*, a name given by Veſalius and others to one of the muſcles of the female pudenda, called by Verheyhen ſimply the *muſculus clitoridis*, but by Albinus and Cowper, *arctor clitoridis*. Verheyhen is not to be cenſured for calling it only the *muſculus clitoridis*, for it is properly the only muſcle of that part, the other generally attributed to the clitoris, and called by Riolan and others, *clitoridis inferior* and *latus*, not properly belonging to that part, but being truly a ſphincter vaginæ, or, as Albinus calls it, the *ſphincter cunni*. See SPHINCTER.

MANIHOT, in *Botany*. See CASSADA.

MANILLE, or MENILLE, in *Commerce*, one of the principal commodities carried by the Europeans to the coaſts of Africa, to traffick with the Negroes in exchange for ſlaves. It is a large braſs ring in form of a bracelet, either flat or round, plain or engraven; with which the natives uſed to deck themſelves, putting them on the ſmall of the leg, and the thick of the arm above the elbow.

The better ſort among the Negroes wear ſilver and gold *manilles*; but theſe are of their own manufacture; moſt of the money they receive for their other merchandizes being melted into *manilles*.

MANIPULATION, a term uſed in the mines, to ſignify the manner of digging the SILVER, &c. out of the earth.

MANIPULUS, MANIPULE, among the Romans, was a little body of infantry, which, in the time of Romulus, conſiſted of a hundred men; and in the time of the conſuls, and firſt Cæſars, of two hundred.

The word properly ſignifies a handful; and, according to ſome authors, was firſt given to the handful of hay which they bore at the end of a pole, to diſtinguiſh themſelves by, before the cuſtom was introduced of bearing an eagle for their enſign: and hence alſo the phraſe, a handful of men. But Vegetius, Modeſtus, and Varro, gave other etymologies of the word: the laſt derives it from *manus*, a little body of men following the ſame ſtandard. According to the former, this corps was called *manipulus*, becauſe they fought hand in hand, or all together: *Contubernium autem manipulare vocabatur ab eo, quod conjunctis manibus pariter dimicabant.*

Each *manipule* had two centurions, or captains, called *manipularii*, to command it; one whereof was lieutenant to the other. Each cohort was divided into three *manipules*, and each *manipule* into two centuries.

Aulus Gellius quotes an old author, one Cincius, who lived in the time of Hannibal (whoſe priſoner he was), and who, writing on the art of war, obſerves, that then each legion conſiſted of ſixty centuries, of thirty *manipules*, and of ten cohorts. And again, Varro and Vegetius mention it as the leaſt diviſion in the army, only conſiſting of the tenth part of a century; and Spartian adds, that it contained no more than ten men. This ſhews, that the *manipule* was not always the ſame thing. See LEGION.

MANIPULUS is alſo an eccleſiaſtical ornament, worn by the prieſts, deacons, and ſubdeacons, in the Romiſh church. It conſiſts of a little ſtiff in form of a ſtole, three or four inches broad, and made of the ſame ſtuff with the chaſuble; ſignifying and repreſenting an handkerchief, which the prieſts in the primitive church wore on the arm, to wipe off the tears they were continually ſhedding for the ſins of the people. There ſtill remains a mark of this uſage in a prayer rehearſed by thoſe who wear it, *Merear, Domine, portare manipulum fletus & doloris.*

The Greeks and Maronites wear two *manipules*, one on each arm.

MANIPULUS, in *Phyſic*, denotes a meaſure, or fixed quan-

tity, of herbs, or leaves, viz. a handful; or ſo much as the whole hand can graſp: it is generally marked in preſcription with *M.*

MANIQUE, in the *Materia Medica*, the name given by authors to an American root, commended greatly for curing tertian and quartan agues, and as an infallible remedy againſt venomous bites. Redi procured ſome of this famous root, and gave it many very fair trials, but could never diſcover any of theſe virtues in it.

MANIS, in the Linnæan ſyſtem of *Zoology*, a genus of brutes in the claſs of *mammalia*, having no teeth, a taper extenſile tongue, a mouth narrowed to the ſnout, and a body covered with ſcales. There are two ſpecies, one with five toes, and the other with four on the feet. See LACERTA *ſquamoſa*.

MANNA, in *Pharmacy*, a medicinal drug, of great uſe in the modern practice, as a gentle purgative, and cleanſer of the firſt paſſages.

Manna is a white ſweet juice oozing from the branches and leaves of a kind of aſh-*tree*, being the aſh-tree with rounder leaf, and of low growth, chiefly in Calabria, during the heats of ſummer.

Manna has been commonly held a kind of *mel aereum*, or honey-dew, which, falling in the night, gathers on certain trees, and even on rocks, and on the earth itſelf; where it hardens with the ſun. But what refutes this opinion is, that ſuch dews melt in the ſun; whereas *manna* whitens and hardens in it. Add, that ſuch dews are only found on the tops and extremes of the leaves; whereas *manna* is chiefly found to lodge near the trunks of the branches: and that the honey-dew falls only on trees open to the air; whereas *manna is* found on trees which are under cover; as was experienced by Dr. Cornelius, who gathered *manna* from branches covered on purpoſe with cloth; and Lobel aſſures us, that *manna* had been gathered from branches of the aſh, which had been thrown the day before into a cellar. It is much more rational to rank *manna* amongſt the number of gums, which, exuding from the juice of the tree, and mixing with ſome ſaline particles of the air, is condenſed into thoſe flakes in which we ſee it.

Manna is far from being peculiar to the aſh-tree of Calabria, on which it is uſually found. It is no other than the matter of the ſenſible tranſpiration of trees and plants in general, and is found on many different kinds in different quantities. The lime and ſycamore uſually have a great deal of it on their leaves in the heats of ſummer, and if ſteeped in water, render it ſweet and purgative. The ſweet matter found in the bottom of the treſoil, or jaſmine flowers, is alſo *manna* in a certain ſtate. The bees are well acquainted with the ſameneſs of this extravaſated juice in different plants, and collect it for their honey, as well from the leaves of the lime and ſycamore, and many other trees, as from the flowers of plants. The elaboration it ſuffers under their management afterwards is all that makes the difference between that and what men collect in Calabria; and honey is *manna* in a certain ſtate.

At Briançon, in France, they collect *manna* from all ſorts of trees that grow there; and the inhabitants obſerve, that ſuch ſummers as produce them the greateſt quantities of *manna*, are very fatal to their trees. Their walnut trees produce annually a conſiderable quantity; but if there happen a year in which they produce more than ordinary, they uſually find many of them periſh in the following winter.

It ſeems very plain from the whole, that *manna* is only the extravaſated juice of the tree, which cannot ſurvive ſo great a loſs of it: and what not a little confirms this is, that the very hot ſummers are always thoſe which are the moſt abundantly productive of *manna*. The ancients were ſenſible of this ſpontaneous production of *manna*, of ſeveral ſpecies of trees, ſo very different from one another, and from thence fell into the error of ſuppoſing it ſomething wholly foreign to the tree; an error very natural to thoſe who did not know that the nutritive juices of very many trees are nearly, if not wholly the ſame. It was from this opinion of its origin, that they called it aerial honey.

Mr. Boyle tells us, that in Apulia and Calabria, between the months of March and November, they obtain, by inciſion, from the common aſh-tree, a ſweet juice ſo like *manna*, in that ſeaſon adhering to the leaves of the ſame kind of trees, that they call it *manna del corpo, trunk-manna*; and uſe it ſucceſsfully. Works Abr. vol. i. p. 51.

The Italians gather three kinds of *manna*:—*Manna di corpo*, which ouſes ſpontaneouſly from the branches of the tree in the month of July. *Manna formata*, or *forzatella*, which is not gathered till Auguſt, after an inciſion of the tree, when the flux of the firſt has ceaſed. *Manna di fronda*, which iſſues of itſelf, in little drops, like a kind of ſweat, from the nervous part of the leaves of the aſh, and gathers into grains about the bigneſs of thoſe of wheat, which are hardened by the ſun in Auguſt. The leaves are frequently found ſo loaden with theſe grains, that they ſeem covered with ſnow.

This is a ſubſtance in many things very nearly related to ſugar and to honey; it is inflammable in the ſame manner, and it melts in water as eaſily as ſugar, and liquefies even in a moiſt air, and by the aſſiſtance of heat, in rectified ſpirit alſo; the impurities only being left by both menſtrua.

M. Lemery, in his analyſis, drew from *manna* a vinous liquor, of the ſame kind with that obtained from honey. Mead may alſo be made of *manna*, in the ſame way that it is made from honey; but it is neither ſo ſtrong, nor ſo agreeable to the taſte as that of honey. From as much mead as was made from two pounds of *manna*, M. Lemery drew off by diſtillation eight ounces of a ſort of brandy, and on rectifying this, procured an ounce and half of a pure burning ſpirit, like in all reſpects to rectified ſpirit of wine. This ſpirit of *manna* is accounted by ſome a ſudorific, and is given from half a dram to a dram and a half. M. Lemery having left the remaining liquor, after the diſtillation of the ſpirituous part of the *manna* mead, in a warm place for two years, found that it depoſited to the bottoms of the bottles ſeven drams of an eſſential ſalt of *manna*, which was white, hard, brittle, and formed into fine needles, and was of an acid taſte, with an admixture of ſweet. This ſalt is purgative, and its doſe is a dram. All the remaining acid liquor being diſtilled, there remained at the bottom of the retort a quantity of matter of the conſiſtence of honey, which weighed twenty ounces; ſo that out of two pounds of *manna*, there had been twelve ounces conſumed, to make the ſpirit, and to give the acidity to the remaining liquor. This honey-like reſiduum, being finally diſtilled with a ſtrong fire, there aroſe a reddiſh liquor of an acrid taſte, and with a ſtrong empyreumatic ſmell, and with this a few drops of a blackiſh oil; after this operation, the remainder in the retort was four ounces of a very light black coal. The coal, it is to be obſerved, is here only one eighth of the weight of the *manna*, which is ſomewhat ſingular, ſince in the pureſt honey, treated in the ſame manner, it always weighs one fourth of the original whole quantity. It is plain from hence, that *manna* is a much purer ſubſtance than honey: it is alſo remarkable, that in farther treatment of this coal, there is a ſmall quantity of iron always diſcovered in it. *Manna*, honey, and all the other ſweet ſubſtances, we ſee, alſo loſe all their ſweetneſs, as ſoon as ever their acid is ſeparated from their oil. Hiſt. Acad. Par. 1708, p. 56.

Manna is a ſafe and gentle purge, and is alſo uſed in broths: Altimarus, a phyſician of Naples, has written a treatiſe expreſly upon it; and Doncella another. *Manna*, though accounted a kind of honey, purges the bile; whereas common honey increaſes it. Formerly the Syrian *manna* was in the moſt repute, but now it gives way to the Calabrian. Fuchſius obſerves, that the peaſants of mount Libanus eat *manna* ordinarily, as others do honey. At Mexico they are ſaid to have a *manna*, which they eat as we do cheeſe.

The *manna* moſt eſteemed is that in flakes; which many take to be factitious, and the work of the Jews at Leghern; but it is certainly natural: and what gives it this figure is, that they put ſtraws and ſlips of wood in the inciſions, along which the *manna* gliding, is condenſed as it comes out, and aſſumes this form.

This beſt ſort, or Calabrian *manna*, is moderately dry, friable, very light, of a whitiſh, or pale yellow colour, and, in ſome degrees tranſparent: the inferior kinds are moiſt, unctuous, and brown. *Manna* of both ſorts, is ſometimes counterfeited by compoſitions of ſugar, honey, and purgative materials, which may be diſtinguiſhed in their ſolid form by their weight, compactneſs, and tranſparency; and in the dry and moiſt ſtate, by their taſte, and by their habitude to menſtrua. *Manna*, in doſes of an ounce and upwards, proves a gentle laxative; it operates in general with great mildneſs, ſo as to be ſafely given in inflammatory or acute diſtempers, where the ſtimulating purgatives have no place. It is particularly proper in ſtomachic coughs; in which intention it is ſometimes made up into a linctus or lohoch, with equal quantities of oil of almonds, and ſyrup of violets. The gripes, flatulencies, and other inconveniencies attending it in ſome conſtitutions, may be obviated by a ſmall addition of ſome grateful aromatic. *Manna* does not produce the full effect of a cathartic, unleſs taken in large doſes, as two ounces or more; and, therefore, is ſeldom employed for this purpoſe by itſelf: it may be commodiouſly diſſolved in the purging mineral waters, or ſharpened with the cathartic ſalts, or other purgatives: its efficacy is ſaid to be much promoted by CASSIA *ſiſtularis*. Lewis.

MANNA is alſo a ſcripture-term, ſignifying a miraculous

kind of food, which fell from heaven, for the support of the Iſraelites, in their paſſage through the wilderneſs; being in form of coriander ſeeds; its colour like that of bdellium, and its taſte like honey.

They called it *manna*, either from the Hebrew word *manah*, *a gift*, to intimate its being a gift from heaven; or from *mennah*, which ſignifies *to prepare*, becauſe the *manna* came to them ready for eating, and needed no preparation but gathering; or from the Egyptian word *man*, *what is it?* which laſt etymology ſeems the more probable, in regard the ſcripture takes notice of the ſurprize they were under when they firſt ſaw this new food deſcend.

Salmaſius, however, preſers another: according to him, the Arabs and Chaldeans uſed the word *man* to ſignify a kind of dew or honey that fell on the trees, and was gathered in great abundance on mount Libanus. On which footing the Iſraelites did not uſe the term *manna* out of ſurprize, but becauſe they found this food fall with the dew, in the ſame manner as the honey-dew, ſo well known to them under the name of *man*. Salmaſius adds, that the *manna* of the Iſraelites was in reality no other than that honey, or dew, condenſed; and that the one and the other were the ſame with the wild honey wherewith St. John was fed in the wilderneſs; ſo that the miracle did not conſiſt in the formation of any new ſubſtance in favour of the Iſraelites, but in the punctual manner in which it was diſpenſed by Providence for the ſuſtenance of ſo vaſt a multitude.

MANNA *alhagina*, a word uſed by ſome authors to expreſs that kind of *manna* called by others *manna maſtichina*, from its drops reſembling maſtic in ſmall tears. It is called *alhagina* from the plant which produces it, it being collected from the *alhagi maurorum*, in the ſame manner as the common *manna* from the Calabrian aſh.

MANNA *libanotis*, in the *Materia Medica*, a name given by the old Greek writers to the ſmall flakes and fragments of the frankincenſe, which flew off the larger pieces in the gathering and putting them up. See LEPTOI *libanotis*.

MANNA *maſtichina*, in the *Materia Medica*, a name given by ſome authors to a kind of *manna* which they deſcribe as reſembling maſtich in its colour, and the ſize of the lumps it is collected in. This is what we uſually know at this time under the name of *manna Perſicum*, or *Perſian manna*, which is at this time in uſe in medicine in the Eaſt, as a common purge.

MANNA *Perſicum*, *Perſian manna*. It does not appear in the writings of the ancient Greek phyſicians, that they were acquainted with any ſpecies of *manna*, though that medicine be now ſo common in the ſhops. They had the word indeed, but they applied it to a very different ſenſe; what they called *manna* being what ſome authors ſtill call the *manna* of frankincenſe, that is, ſuch pieces of the common olibanum as broke off in the carriage from the larger pieces. Philoſ. Tranſ. N° 472. p. 86. in vol. xliii.

The Arabians are by ſome ſuppoſed to have firſt brought what we call *manna* into uſe in medicine; but if they were not the abſolute inventors of this uſe of it, it is certain they were the firſt who made it general and common as a purge. Their country afforded ſeveral diſtinct ſpecies of *manna*, all which ſeem to have been ſo common among them, that they thought deſcriptions of them needleſs; and for that reaſon have not left us ſufficient accounts of them, from which to determine what were their characters and differences. They diſtinguiſhed three kinds of this purging medicine, under three abſolute different names, which were *manna*, *terenjabin*, and *ſtrunjbi*; but it is not eaſily proved whether theſe are all now known, or by what appellations they are at this time diſtinguiſhed.

Rawwolf, in his Itinerary publiſhed by Mr. Ray, and Tournefort in his Voyage to the Levant, have given the cleareſt intimations, in regard to this ſubject, of any of the known writers; and if to theſe we add Cluſius, we have among the three all that is to be expected of any certainty upon the ſubject; yet the deſcriptions of theſe, though eye-witneſſes of all they write, have not prevented ſo eminent and late a writer as Geoffroy from falling into an error concerning the *manna* of the Arabians. It is very evident, however, that we have ſtill one ſpecies of the *manna Arabum*, that is, the *terenjabin*, produced in ſome parts of the world, there having been ſpecimens of it ſent over into England from Peterſburgh, near which place it is collected from a plant known among botanical writers under the name of *alhagi maurorum*.

This is uſually called *manna Perſicum*; it appears at firſt ſight a mixed maſs of a dirty reddiſh-brown colour, but, upon a nearer view, it is ſeen to conſiſt of ſeveral ſorts of particles. Firſt, a great number of globular, cryſtalline, and almoſt tranſparent bodies of different ſizes, and of a yelloviſh white colour; the largeſt of theſe do not much exceed a large coriander-ſeed in ſize, and they have ſomewhat of the appearance of ſmall lumps of maſtic, but are of a ſomewhat reddiſh caſt. Secondly, there is among theſe a large quantity of ſmall prickles, and other little woody bodies, which ſeem to have been the pedicles of leaves. Thirdly, there are a few ſmall leaves, which are of a firm texture, and terminate in narrow points. Fourthly, there are a large number of ſmall long reddiſh-coloured pods, of a ſweetiſh gelatinous taſte, containing from one to ſix or ſeven hard, irregular, and kidney-ſhaped ſeeds, which to the taſte are very four. And fifthly, there is uſually ſome ſand and earth among it. Four ounces of this *manna* diſſolved in water uſually leave about one ounce of theſe ſubſtances in the filtre.

The globules firſt deſcribed are ſomething hard, they break between the teeth like ſugar-candy, and are of a pleaſant ſweet taſte, but have much leſs of the *manna* flavour than the Calabrian, but enough of it to diſcover to what family the ſubſtance belongs: the ſeeds, ſticks, leaves, and pods, ſeem to be all of them parts of the plant which produces the *manna*; and the ſeeds having been ſown with us, have raiſed plants of the alhagi. About the year 1537, when Rawwolf wrote his Itinerary, it appears that large quantities of this kind of *manna* were brought from Perſia to Aleppo, where it was then known by the name of *trunſchibil*, or *trunſchibin*, a corruption doubtleſs of the word *terenjabin*, or, as it ought to be written, according to Deſingius, *tereng jabin*.

Rawwolf alſo expreſly informs us, that this ſpecies of *manna* was gathered from a plant called *alhagi*. This plant is minutely deſcribed by Tournefort, who confirms the account of the *manna* being gathered from it, which Rawwolf had given ſo long before.

Tournefort ſays, that it is chiefly gathered about Tauris, a city of Perſia, under the name of *trunjbin*, or *terenjabin*, mentioned by Avicenna and Serapion; he adds, that thoſe authors thought it fell upon certain prickly ſhrubs, whereas it is really the nutritious juice of the plant; and that, during the great heats in that part of the world, there are perceived ſmall round drops, as it were, of honey ſtanding upon the leaves of this plant; and that theſe harden into globules about the ſize of coriander-ſeeds, and are then gathered by the inhabitants, together with leaves, ſtalks, dirt, and the like foreign matter, which greatly take off from their virtue. Mr. Tournefort obſerves, that this *manna* is greatly inferior to the Calabrian in virtue; and that twenty or thirty drams of it are given for a doſe. Philoſ. Tranſ. N° 472, p. 90. ubi ſupra.

Cluſius tells us, that the *terenjabin* of the Arabians is gathered from a prickly ſhrub, ſuch as the alhagi is deſcribed to be; and Avicenna declares, that it was found upon a thorny plant; though his tranſlators have been miſled from the near reſemblance of two Arabic words, to make it ſtones, not a plant, that it was gathered from.

It appears very plainly from the whole, that this ſubſtance now known in Ruſſia and ſome other parts of the world, under the name of *manna Perſicum*, is truly the TERENJABIN of the Arabians and of Cluſius, Rawwolf, and Tournefort; only that the word is differently ſpelt by the latter authors, and it is probably alſo that *manna* called by Bauhine, and ſome other writers, *manna maſtichina orientalis*, from the round globules it is compoſed of, reſembling the drops of maſtich.

MANNA *thuris*, the *manna of frankincenſe*, a term uſed by the ancient phyſicians to expreſs ſuch ſmall pieces of FRANKINCENSE, or olibanum, as broke off from the larger in the carriage. See LEPTOI *Libanotis*.

MANNER, in *Painting*, &c. expreſſes that particular character obſervable in the works of painters, poets, and other artiſts, by which their pencil, hand, or ſtyle, are diſtinguiſhed.

The curious in pictures know the *manners* of the painters, and diſtinguiſh readily between the *manners* of Rubens, Titian, and Da Vinci; between the ancient and the new *manner* of the ſame painter; and between the Flemiſh, and the Italian *manner*.

Manner is uſed with reſpect both to the invention, the deſign, and the colouring. The *manner* of Michael Angelo, or Raphael, may even be known in their ſcholars. Thus we ſay, ſuch a piece is of Raphael's ſchool, &c.

MANNERS, in *Poetry*, denote the inclinations, genius, and humour, which the poet gives to his perſons, and whereby he diſtinguiſhes his characters.

Ariſtotle defines *manners* to be that which diſcovers the inclination of him who ſpeaks, and ſhews what he will reſolve upon, or what reject, before he was actually determined; whence he concludes, that *manners* have not place always, and in all kinds of diſcourſes.

One inſtance will make this definition clear. In the firſt book of Virgil, Æneas is repreſented extremely pious, and determined

determined to execute the will of the gods, at all adventures. In the fourth book he has a difficult choice proposed; being engaged, on the one hand, out of a principle of love, gratitude, and honour, not to quit Dido; and having, on the other hand, an express order from the gods to depart for Italy. Now, before it appears on which side he has determined, what he has before said, should shew his will and inclinations, and which part he will take. And those preceding discourses, which discover his future resolution, make what we call the poetical *manners*.

Those make it past doubt he will abandon Dido, to obey the gods; this he does in effect; and the *manners*, therefore, are good, and well conducted. Had he disobeyed the orders of Jupiter, to stay with Dido, the *manners* had been ill; because they would have foretold a resolution contrary to what he was really to take. But had there been nothing to make us foresee any resolution of Æneas at all, neither that which he actually took, nor the contrary, in that case there had been no *manners* at all. It is the *manners*, as before observed, that distinguish the characters; and, unless the *manners* be well expressed, we shall never be acquainted with the persons at all; nor, consequently, shall we be either terrified with foreseeing their dangers, nor melted into pity, by seeing their sufferings.

The *manners* should have four qualities; they should be *good*, *like*, *suitable*, and *equal*.

The *manners* are *good*, when they are well marked, or expressed; that is, when the discourse of the persons makes us clearly and distinctly see their inclinations, and what good or evil resolutions they will take. *Likeness* of *manners* only relates to known and public persons, whose characters are in history, with which the poetic characters must agree; that is, the poet must not give a person any quality contrary to any of those which history has already given him. And here it may be observed, that the evil qualities given to princes, and great men, ought to be omitted by poets, if they be contrary to the character of a prince; &c. but the virtues opposite to those known vices ought not to be imposed; as by making him generous and liberal in the poem, who was avaricious in the history.

The *manners* must likewise be *suitable*; that is, they must be agreeable to the age, sex, rank, climate, and condition, of the person that has them. Horace observes, *Interereit multum Davusne loquatur, an heros.* Again, the *manners* must be *equal*; that is, they must be constant, or consistent, through the whole character; or the variety or inequality of the *manners*, as in nature, so in the drama, must be equal. The fearful must never be brave, nor the brave timorous; the avaricious must never be liberal, nor *vice versâ*. In this part, Shakspeare's *manners* are admirable.

Besides these four qualities above mentioned, there is a fifth essential to their beauty; which is, that they be necessary; that is, that no vicious quality, or inclination, be given to any poetic person, unless it appear to be absolutely necessary, or requisite, to the carrying on of the action.

MANNIFERA *arbor*, in the *Materia Medica*, the name by which the round-leaved ASH, on which the manna is found, is often called.

MANNING *a hawk*, in *Falconry*, the making her tractable and tame.

MANNING *the fleet* is the providing of it with a sufficient number of men for any expedition. One of the methods commonly recurred to for this purpose is that of impressing men, by warrants from the lord high admiral to the captains, which are by them assigned to their lieutenants; and to render this the more effectual, vessels, called TENDERS, are hired into the service, to proceed from place to place with those officers and press-gangs, not only to receive volunteers, but to impress any seamen whom they find. The power of impressing men for the sea-service by the king's commission, says judge Blackstone, has been a matter of some dispute, and submitted to with great reluctance; though it hath very clearly and learnedly been shewn by sir Michael Foster, that the practice of impressing, and granting powers to the admiralty for that purpose, is of very ancient date, and hath been uniformly continued by a regular series of precedents to the present time; whence he concludes it to be a part of the common law. The difficulty arises from hence, that no statute has expressly declared this power to be in the crown, though many of them very strongly imply it. The stat. 2 Ric. II. c. 4. speaks of mariners being arrested and retained for the king's service, as of a thing well known and practised without dispute; and provides a remedy against their running away. By stat. 2 & 3 Ph. & M. c. 16. if any waterman, who uses the river Thames, shall hide himself during the execution of any commission of pressing for the king's service, he is liable to heavy penalties. By 5 Eliz. c. 5. no fisherman shall be taken by the queen's commission to serve as a mariner; but the commission shall be first brought to two justices of the peace, inhabiting near the sea-coast, where the mariners are to be taken, to the intent that the justices may choose out and return such a number of able-bodied men, as in the commission are contained, to serve his majesty; and by 7 & 8 W. III. c. 21. 2 Ann. c. 6. 4 & 5 Ann. c. 19. 13 Geo. II. c. 17. &c. especial protections are allowed to seamen in particular circumstances, to prevent them from being impressed. And ferrymen are also said to be privileged from being impressed, at common law; all which do most evidently imply a power of impressing to reside somewhere; and, if any where, it must, from the spirit of our constitution, as well as from the frequent mention of the king's commission, reside in the crown alone.

But, beside this method of impressing, which is only defensible from public necessity, to which all private considerations must give way, there are other means tending to the increase of seamen, and for *manning* the royal navy. Parishes may bind out poor boys apprentices to masters of merchantmen, who shall be protected from being impressed for the first three years; and if they are impressed afterwards, the masters shall be allowed their wages, 2 Ann. c. 6. Great advantages in point of wages are given to volunteer seamen, in order to induce them to enter into his majesty's service, 1 Geo. II. stat. 2. c. 14. It is also usual to premise, by proclamation, a bounty to all seamen and able-bodied landmen, who come into the service by a certain time; and every foreign seaman who, during a war, shall serve two years in any man of war, merchantman, or privateer, in navibus *regis sallo*. 13 Geo. II. c. 3.

About the middle of king William's reign, a scheme was set on foot (7 & 8 W. III. c. 21.) for a register of seamen, to the number of 10,000, for a constant and regular supply of the king's fleet, with great privileges to the registered seamen, and, on the other hand, heavy penalties in case of their non-appearance, when called for; but this registry, being judged to be rather a badge of slavery, was abolished by 9 Ann. c. 21. Blackst. Comm. vol. i. p. 419. &c.

MANŒUVRE, in *Military Language*, consists solely in distributing equal motion to every part of a body of troops, to enable the whole to form, or change their position, in the most expeditious and best method, so as to answer the purposes required of a battalion, brigade, or line of cavalry, infantry, or artillery. The term is also applied to the operation of managing a ship in an engagement.

MANOMETER, or MANOSCOPE, formed from *πανος, rarus*, and *μετρον, mensura*, &c. an instrument to shew, or measure, the alterations in the rarity, or density, of the air.

The *manometer* differs from the barometer in this, that the latter only measures the weight of the atmosphere, or of the column of air over it; but the former, the density of the air in which it is found; which density depends not only on the weight of the atmosphere, but also on the action of heat and cold, &c. Authors, however, generally confound the two together; and Mr. Boyle himself gives us a very good *manometer* of his contrivance, under the title of a *statical barometer*; the structure whereof see under BAROMETER.

The *manometer*, constructed by Mr. Ramsden, and used by captain Phipps, in his Voyage to the North Pole, was composed of a tube of a small bore, with a ball at the end; the barometer being at 29·7, a small quantity of quicksilver was put into the tube, to take off the communication between the external air, and that contained in the ball and the part of the tube below this quicksilver. A scale is placed on the side of the tube, which marks the degrees of dilatation arising from the increase of heat in this state of the weight of the air, and has the same graduation as that of Fahrenheit's thermometer, the point of freezing being marked 32. In this state, therefore, it will shew the degrees of heat in the same manner as a thermometer. But if the air becomes lighter, the bubble inclosed in the ball, being less compressed, will dilate itself, and take up a space as much larger, as the compressing force is less; therefore the changes arising from the increase of heat will be proportionably larger; and the instrument will shew the differences in the density of the air, arising from the changes in its weight and heat. Mr. Ramsden found, that a heat equal to that of boiling water, increased the magnitude of the air from what it was at the freezing point $\frac{1}{28}$ of the whole. Hence it follows, that the ball and the part of the tube below the beginning of the scale is of a magnitude equal to almost 414 degrees of the scale. If the height of both the *manometer* and thermometer be given, the height of the barometer

rometer may be thence deduced by this rule; as the height of the *mannometer* increased by 414 is to the height of the thermometer increased by 414, so is 29.7 to the height of the barometer.

MANONOETOC, in *Natural History*, a name given by the people of the Philippine islands to a species of horned owl, common in those parts.

MANOR, or MANNOR, an ancient lordship, or royalty; consisting of demesnes and services, and of a court-baron, as incident thereto.

The word is formed from the French *manoir*, a *mansion-house*; and that from the Latin *manere, to remain or dwell*; as being the lord's usual place of residence.

Manor is the same with what was formerly called *baronia, barony*.

A *manor* is a kind of noble fee, granted out partly to tenants for certain services to be performed, and partly reserved to the use of the lord's family; with jurisdiction over his tenants, for the lands, or estates, held of him.

For the original of *manors*, we are told there was anciently a certain compass of ground, granted by the king to some man of worth, for him and his heirs to dwell upon, and to exercise some jurisdiction, more or less, within that circuit, such as he thought good to grant; but performing such services, and paying such yearly rent, as by this grant was required. Now the lord afterwards parcelling the same to other meaner men, received rent and services from them, and by that means, as he became tenant to the king, the inferiors became tenants to him.

But at this time a *manor* rather signifies a jurisdiction, and royalty incorporeal, than the land and soil; for a man may now have a *manor* in gross, i. e. the right and interest of a court-baron, with the perquisites, and another enjoy every foot of land belonging to it.

A *manor* may be compounded of divers things; as of an house, arable land, pasture, meadow, wood, rent, advowson, court-baron, &c. And this ought to be, by long continuance of time, beyond man's memory.

It is held by some, that a *manor* cannot now be made, since a court-baron cannot be made; and, without a court-baron, and at least two suitors, there can be no *manor*.

A *manor* may contain one or more villages or hamlets, or only great part of a village; and there are capital *manors* or honours, which have other *manors* under them, the lords whereof perform customs and services to the superior lords. There may be also *customary manors*, granted by copy of court-roll, and held of other *manors*. But it cannot be a *manor* in law, without freehold tenants; nor a customary *manor*, without copyhold tenants. The custom remains, when tenements are divided from the rest of the *manor*, the tenants paying their services; and he who hath the freehold of them may keep a court of survey, &c.

MANSE, MANSUS, MANSA, or MANSUM, formed *a manendo, abiding*, as being the place of dwelling, or residence, in ancient *Law-Books*, denotes a house, or habitation; either with or without land.

MANSE, *capital, manſum capitale*, denotes the manor-house, or lord's court.

MANSUS *presbyteri*, is a parsonage or vicarage-house, for the incumbent to reside in.

This was originally, and still remains, an essential part of the endowment of a parish church, together with the glebe and tithes. It is sometimes called *presbyterium*.

MANSION, *mansio*, a *manendo*, a dwelling-house, or habitation, especially in the country.

Among the ancient Romans, *mansio* was a place appointed for the lodging of the princes, or soldiers, in their journey; and in this sense we read *primum mansionem*, &c. It is with us most commonly used for the lord's chief dwelling house within his fee; otherwise called the capital messuage or manor place; and *mansion* house is taken in law for any house of dwelling of another; in case of committing burglary, &c.

MANSIO, or MANSUS, was sometimes also used in the same sense with HIDE; that is, for as much land as one plough could till in a year.

MAN-SLAUGHTER, is a species of *felonious* HOMICIDE, and denotes the unlawful killing of a man, without any malice, either express or implied; which may be either voluntarily, upon a sudden heat; or involuntarily, but in the commission of some unlawful act. As, when two persons, who before meant no harm to one another, falling out on some sudden occasion, the one kills the other: this is voluntary *man-slaughter*. But in this, and every other case of homicide upon provocation, if there be a sufficient time for passion to subside, and reason to interpose, and the person provoked afterwards kills the other, this is deliberate revenge, and amounts to MURDER. Thus, if a man takes another in the act of adultery with his wife, and kills him directly upon the spot; though this was allowed by the laws of Solon, as likewise by the Roman civil law, if the adulterer was found in the husband's own house, and also among the ancient Goths; yet in England it is not absolutely ranked in the class of *juſtifiable* HOMICIDE, as in the case of a forcible rape; but it is the lowest degree of *man-slaughter*. Further, if two persons play at sword and buckler, unless by the king's command, and one of them kills the other, this is involuntary *man-slaughter*, because the original act was unlawful. So where a person does an act, lawful in itself, but in an unlawful manner, and without due caution and circumspection; as when a workman flings down a stone or piece of timber into a street, and kills a man; this may be either misadventure, *man-slaughter*, or murder, according to the circumstances attending it: if it were in a country village, and he calls out to all people to have a care, it is misadventure only; but if it were in London, or other populous town, where people are continually passing by, it is *man-slaughter*, though he gives loud warning; and murder, if he knows of their passing, and gives no warning at all. The crime of *man-slaughter* amounts to felony, but within the benefit of clergy; and the offender shall be burnt in the hand, and forfeit all his goods and chattels.

By a law of king Canutus, if a man is killed openly and premeditatedly, the murderer shall be committed to the relations of the deceased; but if, on his trial, the fact be proved, but not to have been wilful, the bishop is to judge him.

There is a *man-slaughter* punishable as murder, by statute; by 1 Jac. I. cap. 8. if any person shall stab another, not having then a weapon drawn, or not being stricken first, so that he dies within six months, although it were not of malice afore-thought, it is felony without benefit of clergy; but this doth not extend to persons stabbing others *se defendendo*, or by misfortune, &c. with no intent to commit *man-slaughter*; and the statute relates to the party only that actually gave the stroke, or stabbed the other, and not to those that were aiding or abetting. Blackst. Com.

MANSORIUS *muſculus*, in *Anatomy*, a name given by some writers to that muscle of the face more generally known under the name of the MASSETER.

MANTECU, a sort of preparation of butter used by the Turks when they travel with their caravans. This is first boiled over the fire, and then salted and kept in vessels made of a tough leather, worked round a wooden frame, of the same shape with the vessels in which they bring their balsam from Mecca.

MANTEGAR, or MAN-TIGER, as it is sometimes written, in *Zoology*, is the tufted APE, with a nose and head fourteen inches long; the nose of a deep red, face blue, and both naked; black eye-brows; ears like the human; on the top of the head is a long upright tuft of hair, and on the chin another; two long tusks in the upper jaw; fore-feet like hands, and the nails on the fingers flat; the hind feet have the thumbs less perfect, and the nails imbricated; the fore-part of the body and the inside of the legs and arms naked; the outside covered with mottled brown and olive hair; that on the back dusky; the buttocks red and bare; and the length from the nose to the rump three feet two inches. This animal is very fierce and salacious; will sit on its rump, and support itself by a stick; and in this attitude hold a cup in its hand, and drink out of it; its food is fruit. Pennant. See *Tab.* III. *Quadrupeds*, N° 31.

MANTELETS, in *Military Language*, a kind of moveable parapets, made of planks, about three inches thick, nailed one over another, to the height of almost six feet, generally cased with tin, set upon little wheels, and guided by a long pole; so that in a siege they may be driven before the pioneers, and serve as blinds, to shelter them from the enemy's small shot.

There are also other sorts of *mantelets*, covered on the top, whereof the miners make use, to approach the walls of a town, or castle. See *Tab.* VIII. *Fortif. fig.* 48.

The double *mantelets* form an angle, and stand square, making two fronts, which cover both the front and flank of the sappers, &c. when at work: these have double planks, with earth rammed in between them; they are five feet high, and three in breadth, sometimes covered with plates of iron.

It appears from Vegetius, that *mantelets* were in use among the ancients, under the name of vines; but they were built lighter and much larger than ours, being eight or nine feet high, as many broad, and sixteen long; they were defended by a double covering, the one of boards, the other of faggots, with the ribs of oxen; and were cased without with skins, steeped in water, to prevent fire.

MANTICA, in *Zoology*, the name by which Piso and some other writers have expressed the pouch or bag of skin un-

der the belly of the OPOSSUM, into which the young are received in time of danger.

MANTICHORA, in *Natural History*, a name given by the Roman authors to a fierce and terrible creature, which they describe from the Greeks, who call it sometimes also *mantichora*; but when they write more correctly, *martichora* and *martiora*. We have formed the name *man-tiger* on the sound of the Roman name, though expressing a very different sense; and our authors of the histories of animals, figure to us under this name a terrible creature, partly from the accounts of Pliny exaggerated, and partly from their own imagination, with three rows of teeth, and with such a shape as no animal ever possessed. See MANTEGAR.

The whole story of this animal seems founded on the love of the wonderful; and very probably the *mantichora*, properly speaking, was no other than some of the largest hyænas, which was at first ill described, and afterwards more and more wonders were added to the story, till all shadow of truth was lost.

MANTICLUS, in *Mythology*, a name given to Hercules, under which title he had a temple without the walls of Messina, in Sicily. This temple was built by *Manticlus*, the chief of a colony of Messenians, about 664 years before Christ.

MANTIS, the praying locust. See *Tab. of Insects*, N° 4. and LOCUST.

MANTLE, or MANTLE-*tree*, in *Architecture*, is the lower part of the breast or front of a chimney. It was formerly a piece of timber that lay across the jambs, and supported the breast-work; but by a late act of parliament, chimney-breasts are not to be supported by a wooden *mantle-tree*, or turning piece, but by an iron bar, or by a brick or stone arch. See CHIMNEY.

MANTLE, or MANTLING, in *Heraldry*, that appearance of folding of cloth, flourishing, or drapery, that is in any atchievement drawn about the coat of arms.

It is supposed originally to have been the representation of a *mantle*, or military habit, worn by ancient cavaliers over their armour, to preserve it from rust; or, as others hold, a short covering, only worn over the helmet; which, in after-times, was lengthened, and made to hang from the helmet below the whole shield. See *Tab. Herald. fig. 29.*

The *mantle* is always said in blazon to be doubled, that is, lined throughout with one of the furs, as ermin, pean, vairy, &c. See COAT.

MANTLE *of the Knights of the Garter*. See GARTER.

MANTLE is likewise a term used in *Falconry*. They say the hawk *mantles*, that is, spreads her wings after her legs.

MANTLE, *lady's*, in *Botany*. See LADY'S *mantle*.

MANUAL, *manualis*, signifies what is employed, or used by the hand, and whereof a present profit may be made. Thus such a thing is said to be in the *manual* occupation of one, where it is actually used or employed by him.

MANUAL is the name of a service book used in the church of Rome, containing the rites, directions to the priests, and prayers used in the administration of baptism and other sacraments; the form of blessing holy water, and the whole service used in processions.

MANUAL *exercise*. See EXERCISE.

MANUALIS *lapis*, in *Natural History*, the name of a stone found in America, of which Monardes relates that it has great virtues in curing chaps and cracks in the hands and feet; but he does not describe it.

MANUBIÆ, among the *Romans*, the spoils of the enemy, or rather the money made of the booty, when sold by the quæstor.

MANUCAPTIO, in *Law*, a writ which lies for a man, who, being taken on suspicion of felony, and offering sufficient bail for his appearance, is refused to be admitted thereto by the sheriff, or other having power to let to mainprise.

MANUCMANUC, in *Natural History*, a name given by the people of the Philippine islands to a very beautiful species of parrot, which is found very frequently wild in the woods there. It is of the same bigness with the common parrot, and is variegated with a great many different colours.

MANUCODIATA, in *Ornithology*. See *Bird of* PARADISE.

MANUDUCTOR, a name given to an ancient officer in the church; who, from the middle of the choir, where he was placed, gave the signal for the choristers to sing, and marked the measure, beat time, and regulated the music.

The Greeks called him *mesechoros*, because seated in the middle of the choir; but, in the Latin church, he was called *manuductor*, from *manus*, and *duco*, *I lead*; because he led and guided the choir, by the motions and gesture of the hand.

MANUFACTURE, from *manufactus*, q. d. *made with hands*, a place where several artists and workmen are employed in the same kind of work, or make a commodity of the same kind.

MANUFACTURE is also popularly used to signify the work itself; and by extension, the like work carried on independently in different parts of the country.

In this sense we say, the woollen *manufacture*, silk *manufacture*, velvet *manufacture*, tapestry *manufacture*, muslin *manufacture*, &c. *manufacture* of hats, stockings, &c.

By 23 Geo. II. c. 13. if any person exports any tools or utensils used in the silk or woollen *manufactures*, he forfeits the same, and 200*l.* and the captain of the ship, having knowlege thereof, 100*l.* And if any captain of a king's ship, or officer of the customs, knowingly suffers such exportation, he forfeits 100*l.* and his employment; and is for ever made incapable of bearing any public office.

MANUFACTURERS. Persons enticing artificers into foreign countries, incur the penalty of 500*l.* and twelve months imprisonment, for the first offence, for each person so seduced, and 1000*l.* and two years imprisonment, for the second offence. 23 Geo. II. c. 13. § 1. And such artificers not returning within six months after warning, shall be deemed aliens, forfeit all their lands and goods, and be incapable of any legacy or gift. 5 Geo. I. c. 27. § 3.

MANULCA, in *Antiquity*, that part of the CATAPULTA to which the cord used in working it was fixed.

MANULEA, in *Botany*, a genus of the *didynamia angiospermia* class; the characters of which are, that the calyx is divided into five segments; the limb of the flower is also separated in the same manner, and awl-shaped; the fruit is a double-celled polyspermous capsule.

MANUMISSION, *manumissio*, an act whereby a slave, or villain, is set at liberty, or let out of bondage.

The word comes from the Latin *manus*, *hand*, and *mittere*, *to send*; *quia servus mittebatur extra manum, seu potestatem domini sui.*

Some authors define *manumission* an act by which a lord enfranchises his tenants, who till that time had been his vassals, and in a state of slavery, inconsistent with the fanciity of the Christian faith.

Among the Romans, the *manumission* of slaves was performed three several ways. 1. When, with his master's consent, a slave had his name entered in the census, or public register, of the citizens. 2. When the slave was led before the prætor, and that magistrate laid his wand, called *vindicta*, on his head. 3. When the master gave the slave his freedom by his testament. Servius Tullus is said to have set on foot the first manner; and P. Valerius Publicola the second. A particular account is given of the third in the Institutes of Justinian.

It was not necessary that the prætor should be on his tribunal, to perform the ceremony of *manumission*: he did it any where, indifferently, in his house, in the street, in going to bathe, &c. He laid the rod on the slave's head, pronouncing these words, *Dico eum liberum ajo more Quiritum*, I declare him a freeman, after the manner of the Romans. This done, he gave the rod to the lictor, who struck the slave with it on the head, and afterwards, with his hand, on his face and back; and the notary, or scribe, entered the name of the new-freed man in the register, with the reasons of his *manumission*.

The slave had likewise his head shaved, and a cap given him by his master, as a token of freedom. Tertullian adds, that he had then also a third name given him: if this were so, three names were not a token of nobility, but of freedom.

The emperor Constantine ordered the *manumissions* at Rome to be performed in the churches.

Of *manumission* there have also been various forms in England. In the time of the Conqueror, villains were *manumitted*, by the master's delivering them, by the right hand, to the viscount, in full court, throwing them the door, giving them a lance, and a sword, and proclaiming them free.

Others were *manumitted* by charter. There was also an implicit *manumission*; as when the lord made an obligation for payment of money to the bondman at a certain day; or sued him, where he might enter without suit; and the like.

MANURING *of ground*, the application of a matter proper for meliorating the soil, and rendering it more fertile. The matters used for *manure* are various in various countries: the most ordinary are DUNG, LIME, and MARLE. In some parts of England and Ireland they use sea-shells, as those of cockles, periwinkles, &c. which are found to agree well with boggy, heathy, clayey, wet, or stiff land; as they seem to give it a kind of ferment, as barm does to bread, opening and loosening the clods, and by that means making way for the roots to penetrate, and the moisture

moiſture to enter into the fibres of them. This kind of *manure* continues a long time, before its effects are exhauſted; whereas lime, &c. ſpend themſelves at once. The ſhells, being hard, melt away very ſlowly; ſo that the operation needs not be repeated for twenty or thirty years.

The vaſt beds of foſſile-ſhells, buried in many parts of the world, are not uſeleſs matter, but will ſerve to one of the greateſt purpoſes of huſbandry, the manuring of barren lands. The people of many parts of France, and in ſome places in our own country, dig up the maſſes of broken ſhells, connected into a ſort of ſtrata by marly, or other earths, for this purpoſe; and ſpreading them upon the lands as dung, they ſoon moulder away, and are found extremely beneficial to the earth.

The *manure* of ſhells upon theſe lands does not produce nearly ſo great an effect for the two firſt years, as it does in the ſucceeding ones; the reaſon of which is, that it is not then ſufficiently mixed, but in ſucceeding time it breaks itſelf into a number of very ſmall particles, and theſe all become intimately blended with the molecules of earth, and produce their effect more perfectly.

Sea-ſand is often made uſe of by way of *manure*, in ſome parts of Cornwall, near the ſea-ſhore. When the ſand is much mixed with broken pieces of ſea-ſhells, it is reckoned beſt. It is ſpread upon ſuch land as is intended for wheat, or uſually in the firſt crop of four, whatever be the grain; for after four crops it is the cuſtom in Cornwall to leave the land ſix or ſeven years for paſture before it is tilled again; and the grais will be ſo good the firſt year, where this *manure* is uſed, as to be fit for mowing: this is called *mowing of gratten* by the people there. The Corniſh acre is eight ſcore yards, at eighteen feet to the yard. In one of theſe acres, the farmers beſtow, according to the diſtance from the ſea-ſhore, from three hundred ſacks to one hundred, each ſack containing thirteen gallons, which is called a horſe-load, the roads in many parts of this country being ſo bad, that they are forced to carry the ſand on horſe-back from the waterſide to the land, though eight or ten miles diſtant. In this caſe the ſand coſts them in the whole about eight-pence a load. Where the lands lie very diſtant from the ſhore, and from all water-carriage, they beſtow very little of this *manure*, but they do not care to be any where wholly without it. In ſome of theſe places they lay twenty load on an acre, and find a proportionable advantage from it. Where much ſand is uſed, the corn is large and plentiful, and the ſtraw little. Hence has grown the old Corniſh phraſe of *a buſhel of corn to a peck of ſtraw*; which is not miraculous in a place where the ears of barley are frequently found as long or longer than the ſtalks they grow on.

Where little of this ſand is uſed, there is generally a great deal of ſtraw, and but little and hungry ears of ſmall grain. After the corn is taken off, the graſs that naturally comes up is a white clover; and where the land is any thing deep, a red kind comes up among it. This is uſually but ſhort the firſt year, but it grows thick, and affords good feeding for the cattle; and they are found to thrive the better, and give better milk than when they are fed on the high graſs, which generally ſucceeds where there has been leſs ſand uſed.

Another great advantage of the lands where much ſand is uſed, is, that no ſnow lies upon them; there is a continual winter-ſpring, and an early harveſt, uſually ſix weeks before the neighbouring lands that do not uſe it in proper quantities; ſo that all the expence of procuring it in quantities, is many ways amply repaid to the farmers.

We have about Erith, and many other places, the ſame ſort of ſand in great abundance in the Thames, that is uſed with this great advantage in Cornwall; and if it ſhould be found on trial to anſwer as well, probably there would be found few places where this river would not afford it at ſome depth, or in ſome part of its bed. The coral-ſand of Falmouth is dredged up from under about a foot thickneſs of the ooze; and perhaps in the Thames, where the bottom ſeems of another nature, the ſame ſand, or ſome of equal efficacy, may be found underneath. The ſand taken up out of the Thames at Erith, is uſed by the brick-makers, and they obſerve that the graſs always grows particularly freſh and ſtrong about the edges of their heaps of it, and that clover naturally grows there among other graſs. Phil. Tranſ. N° 113.

Sea-ſand, Dr. Berry obſerves, quickens dead land; ſo that what would otherwiſe be the barreneſt part of that country, is now the richeſt. Sea-ſalt, he obſerves, is too ſtrong and active of itſelf, and that it does beſt when mingled with loam. Glauber orders the mixture to be made up and burnt like bricks, and then applied.

In ſome countries they burn the ſurface of their heathy ground, inſtead of *manuring* it: this others think but all huſbandry, inaſmuch as it impoveriſhes it; and, by deſtroying the ſap of the earth, and roots of the graſs, and other vegetables, renders it uſeleſs for ſeveral years after the third, when it is plowed. See BURNING *of land*.

Dr. Jackſon obſerves, that all the ground about Nantwich, where ſalt or brine is ſpilt, is, when dug up, an excellent *manure* for grazing ground; and even bricks, thoroughly impregnated with it, diſſolve and fertilize land very conſiderably.

Dr. Beal ſays, it is a common obſervation of gardeners, and ſkilful huſbandmen, that froſt and ſnow improve and fertilize the land, both more ſpeedily, and more effectually, than the influence and warmth of the ſun.

Dr. Liſter tells us, that in ſome parts of the North-riding of Yorkſhire, the ſoil is ſandy, and the people manure it with clay. The ſoil, with any other *manure*, bears nothing but rye; but with clay it bears oats, barley, &c. This clay *manuring* will, by certain experience, laſt forty-five years in the ground, before it need be repeated. Burnt clay, in the quantity of about ten large cart-loads on a ſtatute acre, has been found an excellent *manure* for meadow, paſture, or corn: this may be burnt with bruſh-wood or furze; and has been found very uſeful for cloſe, compact ſoils, and wet cold land.

The bogs in Ireland are ſaid to be beſt improved by ſandy, or other gravelly *manures*.

In ſome counties of England, particularly in Oxfordſhire, they uſe, by way of *manure* for ſome of their lands, the cuttings and chippings of ſtones in the quarries, which is ſuppoſed to enrich the land by means of a ſalt that the ſtone contains, which being diſſolved by the weather, is imbibed by the earth.

A new kind of *manure* has lately been introduced with conſiderable advantage; and that is the waſhings of a farm-yard, conſiſting of dung and water, reſerved for this purpoſe in reſervoirs or pools, into which they are ſuffered to drain. This has been ſucceſsfully tried on meadows and fields of wheat, and has been found to yield a conſiderable quantity of graſs and grain. It may be alſo laid to great advantage on land that is freſh ſown with barley, oats, or any other grain; but on graſs it ſhould be only laid in winter time, when the rains will waſh the ſalts off the blade; or in the ſpring, when the lands are laid up for hay; as the cattle will not feed on the graſs, while the dung or ſalt adheres to the blade. This dung-water ſhould likewiſe be carried on the land, not at a time when it rains, but in the dry weather, and at a time when the dung-water in the pools is of a deep brown colour, and ſtrongly impregnated with ſalt. By this means the land may be *manured* from time to time, and the pools kept almoſt empty for the reception of freſh matter every time it rains, and nothing will be loſt. For another uſe to which this dung-water may be applied, ſee POT-*aſhes*.

Oak-bark, after it has been uſed for the tanning of leather, when laid in a heap and rotted, is an excellent *manure*, eſpecially for ſtiff cold land; in which one load of this *manure* will improve the ground more, and laſt longer, than two loads of the richeſt dungs. When this *manure* is laid on graſs, it ſhould be done ſoon after Michaelmas, that the winter rains may waſh it into the ground; for if it is laid on in the ſpring, it will burn the graſs, and inſtead of improving it, will greatly injure it for that ſeaſon. When it is uſed for corn land, it ſhould be ſpread on the ſurface before the laſt ploughing, that it may be turned down for the fibres of the corn to reach it in the ſpring; for if it lies too near the ſurface, it will forward the growth of the corn in winter. Vegetables of moſt ſorts, as the weeds of ponds and ditches, laid up to rot before they begin to ſeed, and mixed with earth or mud, and alſo buck-wheat, vetches, ſpurry, lupines, &c. ploughed into the ground when they are full grown, greatly enrich land. The refuſe of kitchen gardens laid in heaps and rotted, and fern cut down green and tender, and ſuffered to rot, will afford an excellent *manure*. The aſhes of all kinds of vegetables ſpread on the land will much improve it: rotten wood and tan-duſt, when rotted, are a very good *manure* for ſtrong land; ſo are likewiſe bones, horns, and other parts of animals, and alſo decayed fiſh. It may be obſerved in general, that when dung or any other ſoft *manure* is uſed, it ſhould not be laid on the ground till the laſt time of ploughing, when it ſhould be buried as ſoon as poſſible, to prevent the evaporation of the ſalts.

MANUS, was anciently uſed for an oath, and for him that took it as a compurgator. And it often occurs in old records: *tertia quarto, &c.* manu *jurare*; that is, the party was to bring ſo many to ſwear with him that they believed what he vouched was true; and we read of a woman accuſed of adultery: *mulieri huic negativ purgatio facta* manu *extitit indicta*; i. e. *She was to vindicate her reputation upon the teſtimony of ſix compurgators.* Reg. Eccl. Chriſt. Cant. If a perſon ſwore alone, it was *pro-*

feria manus & pedes. The use of this word came probably from its being required at a person's hands to justify himself; or from laying the hand upon the New Testament, on taking the oath.

MANUS *Martis, in Botany*, a name given by some authors to the common cinquefoil, or *quinquefolium vulgare.*

MANUS *interfossi, in Anatomy.* See INTEROSSEI.

MANUSCRIPT, a book, or paper, written with the hand. By which it stands opposed to a printed book, or paper.

A *manuscript* is usually denoted by the two letters MS. and, in the plural, by MSS, or MMSS. What makes public libraries valuable, is the number of ancient *manuscripts* repositied in them. See ALEXANDRIAN, CAMBRIDGE, CLERMONT, COTTONIAN, HARLEIAN, VATICAN, &c.

MANWORTH, in *Old Law-Books*, denotes the price, or value, of a man's head.

In ancient times, every man, according to his degree, was rated at a certain price, according to which, satisfaction was made to his lord, if any one killed him.

MANZEL. See CARAVANSERA.

MAO, or MAU, in *Botany*, a name by which some authors have called the *mapou Indica*, or Indian MANGO-tree.

MAP, a plain figure, representing the surface of the earth, or a part thereof, according to the laws of perspective.

A *map* is a projection of the surface of the globe, or a part thereof, on a plain surface, representing the forms and dimensions of the several countries and rivers; with the situation of cities, mountains, and other places.

Maps are either *universal*, or *particular*.

MAPS, *universal*, are those which exhibit the whole surface of the earth, or the two hemispheres.

MAPS, *particular*, are those which exhibit some particular region, or part thereof.

Each kind are frequently called *geographical*, or *land-maps*, in contradistinction to *hydrographical*, or *sea-maps*, representing only the seas and sea-coasts; and properly called CHARTS.

There are three qualifications required in a *map*: 1. That all places have their just situation with regard to the chief circles of the earth, as the equator, parallels, meridians, &c. because on these depend many properties of regions, as well as celestial phænomena. 2. That the magnitudes of the several countries have the same proportion as on the surface of the earth. 3. That the several places have the *same* distances and situation with regard to each other, as on the earth itself.

For the foundation of MAPS, and the laws of projection, see PERSPECTIVE, and PROJECTION *of the Sphere.*—*The application thereof, in the construction of* MAPS, is as follows.

Construction of a MAP, *the eye being placed in the axis.*—Suppose, v. g. the northern hemisphere to be represented with the eye in a point of the axis, v. g. the south pole: for the plane, whereon the representation is to be made, we take the plane of the equator, and, from all the points of the surface of the northern hemisphere, conceive lines passing through the plane to the eye; which points, connected together, constitute the *map* required.

In this case, the equator will be the limit of the projection; the pole, the centre. The meridians will be right lines passing from the pole to the equator: the parallels of latitude, &c. circles concentric with the equator; and all the other circles, and arches of circles, as the horizon, vertical circles, &c. ecliptic, &c. conceived in that hemisphere, will be ellipses, or arches of ellipses.

The better to apprehend the projection of the circles on the plane, conceive a radiant cone, whose vertex is the eye, its base the circle to be represented, and its sides the rays passing between the circle and the eye. Suppose this cone cut by the plane, it is obvious, that, according to the various position of the cone, there will be a different section, and consequently a different line of representation.

For the application of this theorem in practice.——In a plane, v. g. a paper, take the middle point P (*Vide Geography, fig.* 30) for the pole; and from this, as a centre, describe a circle, of the intended bigness of your *map*, to represent the equator. These two may be pitched on at pleasure, and from these all the other points and circles are to be determined. Divide the equator into 360°, and drawing right lines from the centre to the beginning of each degree, these will be meridians; whereof that drawn to the beginning of the first degree, we suppose the first meridian.

For the parallels.—There are four quadrants of the equator; the first, 0, 90; the second 90, 180; the third, 180, 270; the fourth, 270, 0; which for the better distinction, we will note with the letters A B, B C, C D, D E. Taking one of these, v. g. B C, from the several degrees thereof, as also from 23° 30', and 66° 30' thereof, draw occult right lines to the point D, marking where those lines cut the semidiameter B P C; and from P, as centre, describe arches passing through the several points in P C.——These arches will be parallels of latitude. The parallel at 23° 30', will be the tropic of Cancer, and that at 66° 30', the arctic circle. The meridians and parallels thus described, from a table of longitudes and latitudes, lay down the places; reckoning the longitude of each place on the equator, commencing at the first meridian, and proceeding to the meridian of the place; and for the latitude of the place choosing a parallel of the same latitude: the point wherein this meridian and parallel intersect, represents the place; and in the same manner all the other places may be determined, till the *map* be complete.

For the ecliptic, half of which comes in this hemisphere; we have observed, that it makes an ellipsis; so that the points through which it passes are to be found. The first point, or that wherein the ecliptic cuts the equator, is the same with that wherein the first meridian cuts the equator, which is therefore distinguished by the sign of Aries: the last point of this half ellipsis, or the other intersection of the equator, and ecliptic, viz. the end of Virgo, will be in the opposite point of the equator, viz. at 180°. The middle point of the ellipsis is that wherein the meridian 90 cuts the tropic of Cancer. Thus we have three points of the ecliptic determined: for the rest; viz. for 1° and 15° of Taurus, 1° and 15° of Gemini, 1° of Leo, 1° of Virgo; the declinations of those points from the equator must be taken from a table, and set off in the *map*. See DECLINATION, &c.

Thus where the meridian of 13° cuts the parallel of 5°, that point will be 15 degrees of *Aries*. Where the meridian 27° cuts the parallel 11½, will be the first degree of Taurus; and so of the rest. These points, being all joined by a curve line, will be a portion of an ellipsis representing the ecliptic.

Maps of this projection have the first qualification above required; but they are defective in the second: the surface being stretched farther, as it approaches nearer the equator. For the third, they are still farther erroneous. By this method may almost the whole earth be represented in one *map*, placing the eye, v. g. in the antarctic pole, and assuming for the plane of projection that of some circle near it, v. g. the antarctic circle. Nothing is here required besides the former projection, but to continue the meridian, draw parallels on the other side of the equator, and complete the ecliptic; but this distorts too much for practice.

This projection is of all others the easiest: but that, where the eye is placed in the plane of the equator, is preferred for use. It is, in effect, of the latter kind that *maps* are ordinarily made. The former are added to them, in small, by way of supplement, to represent the intermediate spaces left between the two hemispheres.—Farther, as the situation of the ecliptic, with regard to the earth, is continually changing; strictly speaking, it has no place on the earth's surface: but is used to be represented according to its situation some certain moment; viz. so as the beginning of Aries and Libra may be in the intersections of the first meridian and equator.

Construction of MAPS, *with the eye in the plane of the equator.*—This method of projection though more difficult, is yet much juster, more natural, and more commodious, than the former. To conceive it, we suppose the surface of the earth cut into two hemispheres by the entire periphery of the first meridian, each of which hemispheres we represent in a distinct *map*. The eye is placed in the point of the equator 90° distant from the first meridian: and for the transparent plane, wherein the representation is to be, we take the plane of the first meridian. In this projection, the equator is a right line, and the meridian 90° distant from the first, is also a right line; but the other meridians, and all the parallels of the equator, are arches of circles, and the ecliptic is an ellipsis.

The method is thus. From a point E, as a centre (*fig.* 5.), describe a circle according to the intended bigness of the *map*. This represents the first meridian, and its opposite; for, drawing the diameter B D, there arise two semicircles, the one whereof B A D is the first meridian, the other B C D its opposite, or the meridian of 180°. This diameter B D represents the meridian of 90 degrees, wherein the point B is the arctic pole, and the point D the antarctic. The diameter A C, perpendicular to that B D, is the equator. Divide the quadrants A B, B C, C D, D A, each into 90 degrees; and to find the arches of the meridians and parallels, proceed thus: divide the equator into its degrees; viz. 180 (as being indeed only half the equator); through these several divisions, and the two poles, describe arches of circles, representing meridians, as B 1 D, B 2 D, &c.—How to find centres for describing those arches, see under the word CIRCLE.

Indeed,

Indeed, the operation will be both more eaſy and accurate, if performed by a canon of tangents.

To deſcribe the parallels, the meridian B D muſt be in like manner divided into 180 degrees; then through each of theſe diviſions, and the correſponding diviſions of the quadrants A B, C B, deſcribe arches of circles. Thus ſhall we have parallels of all degrees, with tropics, polars, and meridians.

The ecliptic may be deſigned two ways; for its ſituation over the earth may either be ſuch, as that its interſection with the equator may be over the place A; in which caſe the projection of its ſemicircles, from the firſt degree of Cancer, to the firſt of Capricorn, will be a ſtrait line, to be determined by numbering 23° 30′ from A towards B, and from the extreme of that numeration drawing a diameter through E; which line will be half the ecliptic in this ſituation, and may be divided, as before, into degrees, to which the numbers, ſigns, *&c.* are to be affixed. But if the ecliptic be ſo placed, as that its interſection with the equator is over the place A, in the firſt meridian, its projection in that caſe will be a ſegment of an ellipſis; whereof two of the points are A, C; a third that wherein the meridian 90 cuts the tropic of Cancer. The other points muſt be determined in the manner laid down above; viz. by taking the declinations and right aſcenſions of 15° of Aries, 1° of Taurus, 15° of Gemini, &c. For where the parallels, according to their ſeveral degrees of declination, cut the meridians, taken according to the ſeveral right aſcenſions, thoſe points of interſection are the points of the 15° of Aries, &c. A curve line therefore being drawn, theſe will give the projection of the ecliptic.

Nothing then remains to complete the *map*, but to take the longitudes and latitudes of places from a table; and to ſet them off on the *map*; as was directed under the former method.

In this projection the whole ſurface of the earth may be repreſented in one *map*; if inſtead of the plane of the firſt meridian, ſome other plane parallel to it, but very near the eye, be taken; for by this means the entire parallels and meridians will be deſcribed. But as this diſtorts the face of the earth too much, it is ſeldom uſed; and we rather make the two hemiſpheres in two diſtinct tables.

One great advantage in this projection is, that it repreſents the longitudes and latitudes of places, their diſtance from the pole and from the equator, almoſt the ſame as they really are on the earth. Its inconveniencies are, that it makes the degrees of the equator unequal; being the greater as they are nearer the firſt meridian D A B, or its oppoſite B C D; and for this reaſon equal tracts of the earth are repreſented unequal; which defect may be in ſome meaſure remedied, by removing the eye far from the earth. And, laſtly, the diſtances of places, and ſituation, with regard to each other, cannot be well determined in *maps* of this projection.

Conſtruction of MAPS *on the plane of the horizon*, or wherein any given place ſhall be the centre, or middle. Suppoſe, for inſtance, it is deſired to have London the centre of the *map*. Its latitude we will ſuppoſe to be 51 degrees, 32 minutes. The eye is placed in the nadir. The tranſparent table is the plane of the horizon, or ſome other plane, if it is deſired to repreſent more than an hemiſphere. Take then the point E (*fig.* 6.) for London; and from this, as a centre, deſcribe the circle A B C D to repreſent the horizon, which you are then to divide into four quadrants, and each of theſe into 90 degrees. Let the diameter B D be the meridian, B the northern quarter, D the ſouthern; the line of equinoctial eaſt and weſt ſhews the firſt vertical, A the weſt, C the eaſt, or a place of 90 degrees from the zenith in the firſt vertical. All the verticals are repreſented by right lines drawn from the centre E to the ſeveral degrees of the horizon. Divide B D into 180 degrees, as in the former methods; the point in E B, repreſenting 51 deg. 32 min. of the arch B C, will be the projection of the north pole, which note with the letter P. The point in E D, repreſenting 51 deg. 32 min. of the arch D C (reckoning from C towards D), will be the projection of the interſection of the equator and meridian of London, which note with the letter Q; and from this, towards P, write the numbers of the degrees, 1, 2, 3, &c. As alſo from Q towards D, and from B towards P; viz. 51, 52, 53, &c. Then taking the correſponding points of equal degrees; viz. 99 and 99, 88 and 88, &c. about thoſe, as diameters, deſcribe circles, which will repreſent parallels, or circles of latitude, with the equators, tropics, and polar circles. For the meridians, firſt deſcribe a circle through the three points A, P, C. This will repreſent the meridian 90 degrees from London. Let its centre be M in B D (continuing to the point N, which repreſents the ſouth pole), P N being the diameter; through M draw a parallel to A C; viz. F H, continued each way to K and L. Divide the circle P H N F into 360 degrees, and from the point P draw right lines to the ſeveral degrees, cutting K F H L; through the ſeveral points of interſection, and the two poles P, N, as through three given points, deſcribe circles repreſenting all the meridians. The centres for deſcribing the arches will be in the ſame K L, as being the ſame that are found by the former interſection; but are to be taken with this caution, that for the meridian next B D N towards A, the moſt remote centre towards L, be taken for the ſecond, the ſecond from this, &c. The circles of longitude and latitude thus drawn, inſert the places from a table, as has been directed.

Conſtruction of MAPS *on the plane of the meridian.*——This projection is taught by Ptolemy, and recommended by him as proper for that part of the earth then known. In this, the equator and parallels are arches of circles, and the meridians arches of ellipſes; the eye hanging over the plane of that meridian which paſſes over the middle of the inhabited world. But in regard the deſcription of theſe ellipſes is ſomewhat perplexing, and becauſe this method ſeems calculated only for a part of the earth, it is not now uſed.

There is a ſecond method ſomething akin to it, which repreſents the circles of latitude by right lines, and the meridians by arches of ellipſes; as muſt be the caſe, if lines be conceived to fall from the ſeveral points of each hemiſphere, perpendicularly on the plane of the firſt meridian, and the eye be ſuppoſed at an infinite diſtance from the earth; ſo that all the rays emitted from the places of the earth to it, may be accounted parallels, as well as perpendiculars to the plane of the firſt meridian.

MAPS, *general*, are the hemiſpheres; which are for the moſt part conſtructed ſtereographically.

MAPS, *rectilinear*, are thoſe wherein both the meridians and parallels are repreſented by right lines, which by the laws of perſpective is impoſſible; in regard there can no ſuch poſition be aſſigned the eye and the plane, as that the circles both of longitude and latitude ſhall be right lines.

In the firſt method above laid down, the meridians are right lines, but the parallels are circles: in the fifth, the parallels are right lines, and the meridians ellipſes. In all other perſpective methods, both kinds of circles are curve: one method indeed muſt be excepted, wherein the meridians are right lines, and the parallels hyperbolas; as when the eye is placed in the centre of the earth, and the plane, through which it is viewed, is parallel to the firſt meridian: but this method is rather pretty than uſeful.

Rectilinear maps are chiefly uſed in navigation, to facilitate the eſtimation of the ſhip's way. See CHART.

Conſtruction of particular MAPS.——*Particular Maps of large tracts*, as Europe, Aſia, Africa, and America, are projected after the ſame manner as general ones; only let it be obſerved, that for different parts, different methods may be choſen. Africa and America, for inſtance, in regard the equator paſſes through them, cannot be conveniently projected by the firſt method, but much better by the ſecond. Europe and Aſia are moſt conveniently repreſented by the third; and the polar parts, or the frigid zones by the firſt.

To begin then, draw a right line on your plane or paper, for the meridian of the plane over which the eye is conceived to hang, and divide it into degrees, as before, which will be the degrees of latitude. Then from the tables take the latitude of the two parallels, which terminate each extreme. The degrees of theſe latitudes are to be noted in the meridian; and through them draw perpendiculars, bounding the *map* towards north and ſouth. This done, meridians and parallels are to be drawn to the ſeveral degrees, and the places to be inſerted, till the *map* is complete.

For particular MAPS *of leſs extent.*——In *maps* of ſmaller portions of the earth, the geographers take another method. Firſt, a tranſverſe line is drawn at the bottom of the plane, to repreſent the latitude, wherein the ſouthermoſt part of the country, to be exhibited, terminates. In this line, ſo many equal parts are taken, as that country is extended in longitude. On the middle of this ſame line erect a perpendicular, having ſo many parts as there are degrees of latitude between the northern and ſouthern limits of the country. How big theſe parts are to be, may be determined by the proportion of a degree of a great circle to a degree of the parallel repreſented by the tranſverſe line at bottom. Through the other extreme of this perpendicular, draw another perpendicular, or a parallel to the line at bottom, in which are to be ſeen as many degrees of longitude, as in the lower line, and theſe too equal to each other, unleſs the latitudes happen to be remote from each other, or from the equa-

ter. But if the loweſt parallel be at a conſiderable diſtance from the equinoctial, or if the latitude of the northern limit go much beyond that of the ſouthern; the parts or degrees of the upper line muſt not be equal to thoſe of the lower, but leſs, and that according to the proportion which a degree of the more northern parallel has to a degree of the more ſouthern. After parts have been thus determined, both on the upper and lower line, for the degrees of longitude, right lines muſt be drawn through the beginning and end of the ſame number, which lines repreſent the meridians; then through the ſeveral degrees of the perpendicular erected on the middle of the firſt tranſverſe line, draw lines parallel to that tranſverſe line: theſe will repreſent parallels of latitude. Laſtly, at the points wherein the meridians of longitude and the parallels of latitude concur, infert the places from a table, as before directed. But though there are various modes of conſtructing theſe *maps*, they are, in general defective, ſo as not to be applied with accuracy and facility to the purpoſes intended in determining the courſes or bearings of places, their diſtances, or both.

For MAPS *of provinces*, or ſmall tracts, as pariſhes, manors, *&c.* we uſe another method, more ſure and accurate than any of the former. In this, the angles of poſition, or the bearings of the ſeveral places, with regard to one another, are determined by proper inſtruments, and tranſferred to paper. This conſtitutes an art apart, called SURVEYING.

MAPS, *the uſe of*, is obvious from their conſtruction. The degrees of the meridians and parallels ſhew the longitudes and latitudes of places, and the ſcale of miles annexed, their diſtances; the ſituation of places, with regard to each other, as well as to the cardinal points, appears by inſpection, the top of the *map* being always the north, the bottom the ſouth, the right hand the eaſt, and the left the weſt; unleſs the compaſs uſually annexed ſhew the contrary.

MAPLE, *acer*, in *Botany*, a genus of the *polygamia monoecia* claſs. Its characters are theſe: it hath hermaphrodite and male flowers on the ſame tree; the hermaphrodite flowers have an epalement cut into five parts; the corolla has five petals, eight ſtamina, and one pointal; the flowers are ſucceeded by two winged capſules, joined at their baſe, each including a ſingle ſeed; the male flowers have the ſame characters, but have no ſtyle, ſo are not fruitful. There are twelve ſpecies.

The ſeveral ſorts of this tree are eaſily propagated by ſowing the ſeeds, ſoon after they are ripe, in an open bed of common earth, covering them about half an inch thick with light earth: the ſpring following they will appear above ground, and will grow to a foot high the firſt ſummer. About the Michaelmas following they are to be removed, and planted in rows at three feet diſtance, and two feet diſtance in the rows, in which place they may remain three or four years; and at that time they will be large enough to plant out into the places they are to ſtand in.

The great *maple* commonly, though very improperly called the *ſycamore-tree*, is raiſed very eaſily in this manner, and is a very valuable tree for gentlemen who have plantations near the ſea, as it bears the ſpray of the ſalt-water very well, and will defend all the reſt if planted behind them. The Norway *maple* will alſo anſwer this purpoſe. The timber of the common *maple* is far ſuperior to the beech for all uſes of the turner; and when it abounds with knots is highly eſteemed by the joiners, for inlaying, *&c.* On account of the lightneſs of the wood, it is often employed by the muſical inſtrument makers; and, on account of its whiteneſs, it was formerly much uſed for tables, *&c.*

The Virginian kinds may be propagated, either thus by ſowing, or by laying down the young branches early in the ſpring, giving them a little ſlit at a joint, by which means they will take ſufficient root in a twelve-month to be tranſplanted out. Miller.

MAPLE *ſugar*, a kind of ſugar made from a ſpecies of the *maple*, called by monſieur Sarazin, *acer Canadenſe ſaccariferum fructu minori*. Mr. Sarazin, a phyſician at Quebec, intending to inquire at large into the nature of this ſort of ſugar, obſerved that there were four ſpecies of *maple* common in the places where it was made, all which he ſent over to the garden at Paris. One of theſe ſpecies, diſtinguiſhed from the reſt by the ſmallneſs of its fruit, is called the ſugar-*maple*; this grows to ſixty or eighty feet high, and its juice, which is very redundant in the months of April and May, is eaſily made into a very good ſugar. They procure this juice from the tree by piercing a hole into the trunk, and placing veſſels to receive it. This juice, being evaporated, yields about one twentieth part of its own weight in pure ſugar. A middle-ſized tree, of this ſpecies, will yield ſixty or eighty pints of this juice, without receiving any damage as to its growth; and much more than this may be drawn, but then the tree manifeſtly ſuffers for it.

Mr. Sarazin obſerved ſome very remarkable particulars in regard to the ſaccharine quality of this juice, without which it never had it in the proper perfection. 1. The tree at the time that the juice is drawn out, muſt have its bottom covered with ſnow; and if it is not naturally ſo, the Indians know ſo well the neceſſity of it, that they always bring ſnow from elſewhere, and heap it up round it. 2. This ſnow muſt afterwards be melted away by the ſun-ſhine, not gradually thawed by a warm air. 3. There muſt have been a froſty night before the opening the hole in the trunk. It is remarkable that theſe circumſtances are ſuch as cuſtom and experience alone could have pointed out, ſince they ſeem contrary to reaſon; and ſo it is in many of the operations in chemiſtry, where the moſt ſeemingly rational means fail, while thoſe which ſhould ſeem quite contradictory to reaſon ſucceed. It is obſerved, that if the juice of the *maple* be not in a condition to become ſaccharine while the ſnow lies at its root unthawed, that it almoſt immediately becomes ſo on the melting of the ſnow, and its penetrating into the earth. Mem. Acad. Par. 1730.

The juice of the *maple*, unboiled, has been drank as an antiſcorbutic: the ſugar and molaſſes, which are ſaid to be leſs ſweet than thoſe extracted from the ſugar-cane, are ſuppoſed to be more medicinal in diſorders of the breaſt.

MAPPARIUS, an officer among the Romans, who in the public games, as thoſe of the circus, and of the gladiators, gave the ſignal for their beginning, by throwing an handkerchief (*mappa*) which he had before received from the emperor, conſul, prætor, or other ſupreme officer then preſent.

MARACANA, in *Ornithology*, the name of a bird of the parrot-kind, but larger than the common ſpecies, and covered all over with bluiſh-grey feathers. It is very common in the Braſils.

The natives alſo call another bird of the parrot-kind by the ſame name, which is of a fine green on the head, neck, and back, but the crown of the head looks a little bluiſh; the tail is mixed of red and a bluiſh-green; the under part being red, as is alſo the under part of the wings; at the origin of each wing, it has alſo a red ſpot; and on each ſide of the head a brown one. The noiſe this bird makes, is oe, oe, oe.

MARACOCK, in *Botany*; ſee PASSION-*flower*.

MARANA, in *Botany*, a name by which ſome authors have called the ſtramonium, or thorn-apple, a plant kept in ſome gardens.

MARANTA, in *Botany*; ſee *Indian* ARROW-*root*.

MARASMUS, Μαρασμος, derived from the verb μαραινω, *to waſte*, in *Medicine*, an extreme waſting, or conſumption of the whole body.

A *maraſmus* is an extreme degree of atrophy; as an hectic fever is an extreme degree of *maraſmus*.

MARAUDING, from the French, *maraude*, in *Military Language*, is a term applied to a party of ſoldiers, who, without any order, go into the neighbouring houſes or villages, when the army is either in camp or garriſon, to plunder and deſtroy, *&c.*

MARAVEDI, a little Spaniſh copper COIN, worth ſomewhat more than a French denier, or half a farthing Engliſh.

The word is Arabic, and took its riſe from the *Almoravides*, a dynaſty of Moors, who, paſſing out of Africa into Spain, impoſed their own name on this coin, which by corruption was afterwards changed into *maravedi*.—Mention is made of it in the Decretals, as well as in other Latin writers, under the name of *maravitinus*.

The Spaniards always count by *maravedis*, both in commerce and in their finances, though the coin itſelf is no longer current among them. Sixty-three *maravedis* are equivalent to a rial of ſilver; ſo that the piſtler, or piece of eight rials, contains five hundred and four; and the piſtole of four pieces of eight, two thouſand and ſixteen *maravedis*.

This ſmallneſs of the coin produces vaſt numbers in the Spaniſh accounts and calculations; inſomuch that a ſtranger or correſpondent would think himſelf indebted ſeveral millions for a commodity that coſt but a few pounds.

In the laws of Spain, we meet with ſeveral kinds of *maravedis*; Alphonſine *maravedis*, white *maravedis*, *maravedis* of good money, *maravedis* Combrenſes, black *maravedis*, and old *maravedis*. When we find *maravedis* alone, and without any addition, it is to be underſtood of thoſe mentioned above. The reſt are different in value, fineneſs of metal, time, *&c.* Mariana aſſerts, that this coin is older than the Moors; that it came from the Goths; that it was anciently equal to a third

part of the rial, and consequently of twelve times the value of the present *maravedi*. Under Alphonsus XI. the *maravedi* was seventeen times; under Henry II. ten times; and under Henry III. five times; and under John II. two times and an half the value of the present *maravedi*.

MARBASIS, in *Botany*, a name given by some to a kind of plant which they say climbed up trees, and there hung down from their branches in form of long jointed and naked filaments.

The word seems to be only a corruption of the word *ambasis* of Pliny, which he calls also EPIMEDIA, and gives the same character to.

The *marbasis* of the ancients seems to mean our GENEA.

MARBLE, MARMOR, a precious kind of stone, found in great masses, and dug out of pits or quarries; being of a constitution to hand and compact, and a grain so fine, as readily to take a beautiful polish: much used in ornaments of buildings, as columns, statues, altars, tombs, chimney-pieces, tables, and the like.

The word comes from the French *marbre*, and that from the Latin *marmor*, of the Greek μαρμαιρω, *to shine*, or *glitter*.

Aforisis make a peculiar genus of fossils, the characters of which are these: they are bright and beautiful stones, composed of small separate concretions, moderately hard, not giving fire with steel, and fermenting with and soluble in acid menstrua, and calcining in a slight fire.

There is an infinite number of different kinds of *marble*, and they are usually denominated, either from their colour, their age, their country, their grain, their degree of hardness, their weight, or their defects: some are of one simple colour, as white or black; others streaked or variegated with stains, clouds, waves, veins, &c. but almost all are opake, excepting the white, which, when cut in thin slices, becomes transparent.

By these characters the *marbles*, properly so called, are distinguished from the PORPHYRITES and GRANITES, which are properly stones of a very different kind, being composed of very different particles, and exhibiting contrary properties. Sir William Hamilton observes, that many variegated *marbles* and precious stones are the produce of volcanos. Phil. Trans. vol. lviii. p. 12.

MARBLES, *ancient*, are those, whose quarries are lost, or inaccessible to us, and whereof we have only some wrought pieces remaining.

MARBLES, *modern*, are those, whose quarries are still open, and out of which blocks continue to be dug.

The *marbles* are a genus of bodies supposed to be very well known, because seen every day, and in common use; but they are in reality, notwithstanding that, perhaps one of the most confused, and least understood of all the bodies of this kind. The people who work upon them, know nothing more of them than that this will, and that will not receive a polish in a high degree; and that this may be worked, and another refuses the tools; and the men of science have considered them even less than these.

The *marbles* were one of those sets of bodies that the ancients were well acquainted with, and it may give no small light into their true history, to pay a strict attention to what they have left us concerning them, and inquire which of those in use among them are known to us, and which lost, and by what names we now call their *Augusteum*, *Tiberianum*, *Lucullæum*, and the rest. This may serve to give a certain account of what they knew, and perhaps may point out to the builder, statuary, and physician, some new uses, at least new to us, of many of them. Hill's Hist. of Foss. p. 361.

Mr. Mendes da Costa, in his History of Fossils, has arranged the different species of *marbles* into four general divisions. The first division comprehends those of one plain uniform colour, the kinds of which are easily distinguished: and this division includes the black, white, ash and grey, brown and red, yellow, blue, and green *marbles*. The second division contains those *marbles*, which are only of two colours: and in this division he has first placed the *marbles*, whose chief or ground colour is black, variegated with the other colours; as black with white, black with ash and grey, black with brown and red, with yellow, with blue, and with green, all in their due order: and in the same manner he has proceeded with all the other chief colours, e. g. white with black, with grey, brown, red, &c. ash and grey *marbles*, variegated with other colours; brown and red *marbles*, variegated with other colours, &c. His third division comprehends those *marbles*, that are variegated with many colours. And his fourth division includes those that contain shells, corals, and other extraneous bodies. At the end of each section he has given a list or catalogue of all the *marbles* of these colours, slightly mentioned by authors, and which seem of different species from those which he has described. By this regular arrangement of colours, which he has pursued through the whole genus, he has made it easy for his readers readily to find whether a *marble*, as far as his knowledge extends, has been hitherto described or not, or whether there are any which approach it in colour, on only reviewing the single section where those colours are arranged.

MARBLE, *African*, has a black ground, diversified with moderately large white spots, which do not communicate with each other: they are sometimes also tinged a little reddish, and the *marble* has some marcasitical grains intermixed with it. It admits a good polish, and will not strike fire with steel.

MARBLE, *Alabandinum* MARMOR, a name given by the ancients to a very remarkably glofsy species of black marble, dug near a city of that name in Caria, and much used in building among the Romans.

MARBLE, *Augustan*. See *Egyptian* MARBLE.

MARBLE of *Antwerpen*, in France, is of a pale red, mingled with violet, green, and yellow.

MARBLE of *Brabanton*, in Hainault, is black veined with white.

MARBLE of *Breccia*, in Italy, is yellow, with spots of white.

MARBLE, *Brocatello*, is mingled with little shades of Isabella, yellow, pale, and grey. It comes from Tortosa in Spain, where it is dug out of an ancient quarry. There is also another kind of ancient *Brocatello* dug near Adrianople. There is also an Italian *marble*, called *Brocatello*, which is elegant and beautiful, of a fine bright yellow colour, thickly variegated with irregular veins and spots of purple, and spots or spaces of fine pellucid crystallized spar, and also of semipellucid spar: the polish is admirable, and equal to that of the finest agate; but its surface is not perfectly smooth, being generally somewhat flawed.

MARBLE, *Cavaggion*, is an Italian *marble*, so called from its flesh-like colour, exhibiting shades of a pale, whitish, and yellowish cast, and also of a rosy hue, stronger in some parts than others. It is capable of a very fine polish.

MARBLE of *Carrara*, on the coasts of Genoa, is very white, and fittest of all others for works of sculpture. See *Parian* MARBLE.

MARBLE, *Carystium* MARMOR, a name given by the ancients to a species of *marble*, dug in the island of that name, and much used in ornamenting the public buildings; it was of a beautiful green, deeper than the Thessalian and Augustan *marble*. We meet with it sometimes among ancient remains; and the Italian antiquaries particularly mean this, by a name also in use among us, and prostituted to every other species of green *marble*, the *verde antique*.

MARBLE of *Champagne* resembles the Brocatello, being mixed with blue, in round stains, like partridges eyes.

MARBLE, *Chernitian*. See CHERNITES and *Lydium* below.

MARBLE, *Chium* MARMOR, in the *Natural History of the Ancients*, the name of a black *marble*, called also the lapis obsidianus. It is very hard, and of a fine black: and beside the many uses which the antients put it to, is well known among our goldsmiths by the name of the touch-stone, most of them being furnished with nothing better for that purpose than a piece of this, though the basaltes, which might be had plentifully enough, is greatly preferable for those uses; any black *marble*, however, that is tolerably hard will do.

MARBLE, *Cipolino* or *Cipollin*, the true Egyptian *marble*, is of a sea-green colour, mixed with large waves or clouds of white or pale green. Scamozzi takes this to be the same with that which the ancients called *Augustum & Tiberium marmor*; because discovered in Egypt in the times of Augustus and Tiberius. This *marble* is dug in Italy, and is called *Cipollaccio*, from its leek-like colour: or, according to others, from its veins sometimes running within one another, like the coat of an onion. This is supposed to be the same with the *Carystium marmor* of the ancients.

MARBLE, *Corallitium* MARMOR, of the ancients, was found near the river Coralius, otherwise Sangarus, in Phrygia, and resembled ivory. It was probably the same with the CHERNITES.

MARBLE, *Corallitic*, in *Natural History*, the name given by authors to such *marbles* as have specimens of the marine corals, or bodies of that kind, immersed in them; as the sea-shells are buried in, and make a part of the body of others.

There are several species of *marble* subject to hold these bodies, but we have in England principally two in use, the one of a greyish black, the other of a fine deep jetty black.

The first is found in many parts of Derbyshire, and the corals it contains are of the porus kind, and of one of the

the moſt elegant ſpecies in the world; they are lodged in it at all angles, and in all directions, and are in general about an inch and half long, and three quarters of an inch broad, though ſome are much larger, and others ſmaller. They are compoſed of longitudinal plates, very fine and thin, and of a ſnow-white, ranged in diſtinct orders, and finely interſperſed at ſmall diſtances, with thin tranſverſe plates; the whole internal part of the coral being thus divided into a ſort of ſquare cells. This net-like diviſion runs through about three-fourths of the body, but the top has only the longitudinal plates without the tranſverſe ones. It is plain that theſe, before they were received into the bed of *marble*, had been ſuſtained in a fluid containing a very beautiful greyiſh-white ſpar, for the net-like plexus of the bed is full of this matter; but the open part at top having no plates for the retaining this matter, has remained empty till received into the *marble*, and is there found filled up with the common blackiſh matter of the reſt of the ſtratum. It is an extremely beautiful ſubſtance when poliſhed, and is uſed in many ornamental works. It is found in many parts of Derbyſhire, and in Wales.

The other, or black *coralloide marble*, is alſo a very beautiful ſpecies; it is a very cloſe compact ſubſtance, and of a fine even texture, very hard, of a deep jetty black, and capable of a high poliſh. It is elegantly variegated with fair and perfect ſpecimens of a coralloide pores, approaching to the nature of the former, but ſmaller and of a leſs elegant texture; and among theſe has uſually a great number of ſea-ſhells, both of the turbinated and bivalve kinds. Theſe are lodged in various directions, and all of them, the corals as well as the ſhells, are of a pure ſnow-white; and as the matter and texture of the others plainly ſhewed, that they had been filled with ſpar before they were immerſed into the bed of *marble*; theſe, on the other hand, retaining now no part of their original texture, though exactly their external figure, but being all made up of the ſame plain white ſpar, plainly ſhew that they were lodged in the *marble* empty, and in their own native ſtate; for the cavities both of the corals and ſhells are all nicely filled with the matter of the *marble*; but they have now no coralline nor teſtaceous matter about them, but in tract of time have plainly periſhed, and the cavities they left in the hard and ſmooth maſs of the *marble* have been nicely and finely filled up with this ſpar, which therefore now as perfectly repreſents their figures, as if themſelves were there. Hill's Hiſt. Foſſ. p. 473.

It is found in great plenty in many parts of Ireland, particularly about Kilkenny, and is brought in great quantities to London, and uſed about chimney-pieces, and other ornamental works, and is commonly known among artificers by the name of Kilkenny-*marble*.

MARBLE, *Derby*, among our artificers, a name given to a very beautiful ſpecies of *marble*, found in many parts of Derbyſhire, and frequently worked into chimney-pieces in London.

It is a very ſingular and beautiful ſpecies; its conſtituent matter is a pale, fine, whitiſh-brown *marble*, of a fine cloſe texture, and very bright and glittering hue. This is ſo full of entrochi, that they make more than half the ſubſtance of the maſs; and theſe cutting in different directions, and taking a fine poliſh, add greatly to the beauty of the whole, when wrought. Hill's Hiſt. of Foſſ. p. 479.

The various forms in which theſe bodies appear in the ſtone, when cut, might give a ſuſpicion that many of them were ſome other foſſil; but this is only owing to their lying in all directions in the maſs; but when nicely examined, the oddeſt of them will be found to be no other than what a ſingle common entrochus may be cut into. They are of all ſizes, from the thickneſs of a large pin, to half an inch or more.

MARBLE, *Docimenum* MARMOR. See DOCIMENUM.

MARBLE, *Egyptian*, a name given by our artificers to a very beautiful green-and-white *marble*, greatly in uſe among us, and brought in great quantities from Egypt, and other places. It was alſo in frequent uſe, and in great eſteem, among the Romans, who received it alſo from Egypt, and diſtinguiſhed, without ſufficient reaſon, two kinds of it, from the different diſpoſition and order of its variegations, and honoured them with the names of two of their emperors, in whoſe reigns they were firſt brought into uſe. Theſe were the *marmor Auguſteum* and *Tiberianum*. Thoſe pieces in which the variegations were waved and thrown into arches and circular figures, they called the *Auguſtan*, and thoſe which were marked with more diſtuſed and ſcattered veins, they called the *Tiberian*. Theſe were the whole differences between the two; and if we were to acknowledge different ſpecies from ſuch differences as theſe, we muſt allow almoſt as many different ſpecies as we can ſee blocks of *marble*.

This kind of *marble*, in all its appearances, is, though a very beautiful, yet a very rude, irregular, and various maſs. It is of a firm compact texture, and moderately heavy, and may be properly called a green *marble* variegated with white, for thoſe are its two conſpicuous colours; but it has theſe mixed in ſo great a variety as to afford lights and ſhades of a vaſt number of degrees of colours. It has beſides theſe, alſo many other variegations of a duſky colour approaching to black. It is very bright and glittering, when freſh broken, and variouſly ſo in its various parts. In the white parts it is brighteſt of all, and the other colours are more lucid as they are paler, or nearer approach to the white. It has, however, among its other particles, ſome of a very beautiful green ſoliaceous talc. The whole is capable of a good poliſh, and is common in tables, &c. in the houſes of the polite part of the world. Hill's Hiſt. Foſſ. p. 481.

MARBLE of *Dinan*, near Liege, is of a pure black, very beautiful, and very common.

MARBLE *fuſile*, a very common but very improper term uſed for the green or greeniſh grey *marble*, full of ſmall ſea ſhells, of which the ſlender pillars of our Gothic buildings are made. The two kinds of *marble* called by this general name are diſtinguiſhed by Dr. Hill, by the names of, 1. *marmor viridi-cinereum conchyliis frequenter aſperſum*; green *marble*, thick ſet with ſea ſhells: and, 2. *marmor cinereo-viride conchyliis paucioribus refertum*; greyiſh green *marble*, more thinly interſperſed with ſea ſhells. The firſt is moſt frequent in Italy, and is the *fuſile marble* of that part of the world: and the ſecond is dug in Derbyſhire, Dorſetſhire, Suſſex, and many other parts of England, and is what the pillars in our cathedrals are made of, and is conſequently the ſpecies called *fuſile marble* in England. Hill's Hiſt. of Foſſ. p. 470.

From the length and ſlenderneſs of thoſe columns it has been vulgarly ſuppoſed, that they were caſt in moulds, but reaſon and a knowledge of nature ſufficiently explode the conjecture, ſince we well know that *marble* will burn to lime inſtead of melting in the fire, and that the ſhells it contains muſt have been calcined to powder alſo, not having been found as they now are, if it were poſſible that *marble* could have been run.

We have in England, in many places, vaſt quarries of *marble*, all full of ſea ſhells, and theſe pillars have been all cut out of the *marble* of ſuch quarries. The ſhells it contains are of different kinds, ſome turbinated, and others bivalve, and of the tellina and pectunculus kind; and theſe being filled with a pure and white ſpar, give a fine variety to the whole *marble* when wrought.

MARBLE of *Gnacheret*, near Dinan, is of a reddiſh brown, with white ſpots and veins.

MARBLE, *Herboſum* MARMOR. See HERBOSUM.

MARBLE, *Hymettium* MARMOR, a name given by many of the old writers to a ſort of white *marble*, ſometimes variegated with other colours, but remarkable for its great gloſs, and the high poliſh it was capable of: this was greatly uſed among the Romans for the columns of their public buildings.

MARBLE, *Jaſſenſe* MARMOR, a name given by the ancients to a very beautiful ſpecies of *marble*. It was remarkably hard, capable of a very fine poliſh, and was of a beautiful red approaching to what we call blood-colour, elegantly variegated with veins and clouds of a bluiſh white.

MARBLE, *Italian*, a name uſed by our artificers for two or three of the variegated *marbles*, of great beauty, commonly wrought into chimney-pieces and other ornamental things.

The name is a very indeterminate one, many of the plain, as well as the variegated *marbles*, being from Italy, and indeed many of the variegated ones which have other peculiar names, though known to be brought from Italy, being never called by it; ſo that if any meaning is to be fixed to the word at all, it muſt be ſaid to mean ſuch of the variegated foreign *marbles* as are not diſtinguiſhed by any other peculiar title.

The artificers chiefly comprehend, however, under this name, five ſpecies: 1. The common purple and white variegated one. This is a very beautiful maſs, and in general moderately fine, but of very different degrees of purity and hardneſs in its different parts. It is, in general, white, veined, ſpotted, and variegated with purple; but, in ſome blocks, the purple makes the ground, and the white the variegation, and in moſt it is variegated beſide with ſpots of pale red and brown, ſometimes of yellow, and ſometimes of a greeniſh brown. This is the moſt common *marble* of Italy. 2. A brown and white friable one. This emulates the figure of the former in the diſpoſitions of its veins, but is only of a white ground, veined with a duſky brown, and is the ſofteſt of all the *marbles*. The white part of it appears compoſed of granules, looſely hung together, and, on a near view, much reſembles loaf-ſugar of the fineſt kind, an

and if scraped with a knife readily falls away in large granules like sand. This is also common in Italy. 3. A hard variegated blue and white *marble*. This is a somewhat coarse *marble*, of a rough grain, and of a loose shattery texture, and is variegated with a dusky blue, and a pearl colour or bluish white, each making usually an equal part of the mass. This is very common in Italy, and great quantities of it are imported hither. 4. A fine black and yellow one, the yellow veins appearing like streaks of gold. This is much esteemed and used. And, 5. A purple and yellow one, of great beauty, and very great price. This last of late been sold at a higher rate than ordinary. Hill's Hist. of Foss. p. 476, 477, 478.

MARBLE, *Kilkenny*. See *Cipollinis* MARBLE *fasperis*.

MARBLE, *Lacedæmonium* MARMOR. See LACEDÆMONIUM.

MARBLE of *Languedoc* is of a vivid red, with large white veins or flains, and is very common: there is also, whole white boulders pretty much on the blue; but this is of less value.

MARBLE of *Lisnoe*, in Maine, has a black ground, with little narrow veins of white: there is another kind of it, red with veins of dirty white.

MARBLE, *Lucullum* MARMOR. See LECHEUM.

MARBLE, *Lucullæum* MARMOR. See LUCULLEUM.

MARBLE, *Lumachella*, is so called, because mingled with spots, brown, black, and white, formed of periwinkle-shells petrified in it. This is ancient, and its quarry is loft.

MARBLE, *Lunense* MARMOR. See LUNENSE.

MARBLE, *Lychnites* MARMOR, in the *Natural Hiftory of the Ancients*, a name given by many to the *Parian* MARBLE, of which the fineft ftatues among the ancients were formed.

Varro imagines that it had this name from λυχνος, a *lamp*, becaufe, as he fuppofes, it was cut by candle-light in the quarries; but it feems much more probable, that it had it from the verb λευκαινω, *to fhine*, or *be bright*, from its remarkable fplendor.

MARBLE, *Lydium* MARMOR, a name given by the ancients, not only to the black *marble*, ufed as a touch-ftone for the trial of gold, See but alfo to another very different one brought from the fame place; the ground of which was red, and the veins, which were very numerous, and ufually beautifully difpofed, were white. This was an elegant *marble*, and was ufed in moft of the public buildings for pavement, and covering the inner fide of the walls.

MARBLE, *Lygdinum* MARMOR, in the *Natural Hiftory of the Ancients*, the name of a fort of alabafter, which may properly be diftinguifhed by the name of the white kind. It is a very elegant and beautiful ftone, of a whitenefs greatly fuperior both to the Parian *marble* fo famed of old, and to the Carrara of the moderns; and in fplendor greatly furpaffing all the *marbles* clafs. It is of a loofe, rough, and fhattery texture; and when broken, is feen to be compofed of a multitude of *broad*, *flat*, and large particles, of a very bright, and perfectly white *marble* tone. It is always found pure and free from veins, and is moderately hard in the mafs, but eafily crumbles in fmall pieces; it is however eafily cut, and takes a very high and elegant polifh. It is found in immenfe ftrata in Egypt and Arabia, and is not uncommon in Italy. It is feldom found in large blocks, the ftrata being, from the nature of the ftone, fubject to very frequent perpendicular fiffures. And the ancients give us the fame account of it, and ufed it for making vafes and other ornamental furniture. Hill's Hift. of Foff. p. 492.

MARBLE of *Margelia*, in the Milanefe, has a white ground, with brownifh veins, refembling the colour of iron-rufl. This is very common, and extremely hard.

MARBLE, *Melleum* MARMOR, in *Natural Hiftory*, the name of a plain yellow *marble*, refembling honey or pure Venice turpentine in colour, and thence called by Caffiodorus, *marmor fpecie mellis aut ftrobinthino*. It is a very beautiful *marble*, though but of one plain colour, and it is a wonder it is not more imported into England. It is of a very agreeable colour, and is confiderably hard, and capable of a very elegant polifh. It is dug in many parts of Italy, and is greatly efteemed there. It never has any veins. Hill's Hift. of Foff. p. 464.

MARBLE of *Namur* is a fpecies of black *marble*, very hard and capable of a good polifh, without any variegations of other colours. It is dug near the city of Namur, and is common in Italy, France, and Germany. It is chiefly ufed for monuments, tomb-ftones, and fuch purpofes. See LUCULLEUM *Marmor*.

MARBLE, *Nomadicum* MARMOR, in the *Natural Hiftory of the Ancients*, the name of a peculiar fpecies of *marble*, which was of no great beauty, but fingular in its remarkable hardnefs, and capable of a very elegant polifh. It feems to have been one of the firft *marbles* the Romans brought into ufe in pavements. It is a very firm, hard, and ftrong kind, of a clofe texture, and in colour of a pale afh-coloured blue. It is found in Italy, Spain, France, and Germany, but no where fo plentifully as in the laft country. It is a very durable and ftrong kind: but its want of variety in colour, makes it but little eftemed. Hill's Hift. of Foff. p. 463.

The inhabitants of Namur and Holland call it the blue ftone.

MARBLE, *Obfidianus*. See OBSIDIANUS *Lapis* and *Onyx* above.

MARBLE, *Parian*, is antique, and much celebrated in authors; it is of a beautiful white: the greateft part of the Grecian ftatues were made of it. Varro calls it *ftellaries*, becaufe the workmen dug it out of the quarry by lamplight.

It is called by us, at this time, *ftatuary marble*.

Too many of the later writers have confounded all the white *marbles* under the name of the *Parian*; and among the workmen, this and all the other white *marbles* have the common name of *alabaflers*; fo that it is in general forgotten among them, that there is fuch a thing as alabafter different from *marble*; which however, is truly the cafe. Almoft all the world alfo have confounded the Carrara *marble* with this, though they are really very different; the Carrara kind being of a finer ftructure and clearer white than the *Parian*, but lefs bright and fplendid, harder to cut, and not capable of fo glittering a polifh.

The true *Parian marble*, fays Hill, has ufually fomewhat of a faint bluifh tinge among the white, and often has blue veins in different parts of it. But Da Coffa denies that thefe blue ftreaks are ever obfervable in the true *Parian marble*, which is always of a pure white throughout; whereas, he fays, the Saligno *marble* has fome admixture of that colour.

It is fuppofed, by fome, to have had its name from the ifland Paros, one of the Cyclades in the Ægean fea, where it was firft found; but others will have it to have been fo called from Agoracritus Parius, a famous ftatuary, who ennobled it by cutting a ftatue of Venus in it. Hill's Hift. of Foff. p. 462.

This *marble*, according to Pliny, was fent for from Egypt, to adorn the frontifpiece of that celebrated labyrinth, which was counted one of the wonders of the world.

Among the many famous ftatues of antiquity cut of this *marble*, the valuable and elegant ftatue of LAOCOON and his two fons, mentioned by Pliny, l. xxxvi. c. 5. has efcaped the injuries of time, and is yet preferved at Rome, as are alfo three other elegant ftatues of this *marble*, of Apollo, Antinous, and the trunk of a ftatue, fuppofed to have been of Hercules, which is called by the common people *il Torfo*.

MARBLE of *Porta Santa*, at Rome called *Serua*, is mingled with large clouds and veins of red, white, and grey.

MARBLE, *Porter*, has a black ground, with clouds and veins of yellow. It is dug out of the foot of the Alps towards Carrara.

MARBLE of *Rance*, in Hainault, is of a dirty red, mixed with blue and white clouds and veins: this is pretty common; but is different in degree of beauty.

MARBLE of *Sarza* is of a deep red, mixed with other colours; each piece whereof feems cemented on to the reft.

MARBLE of *Sicily* is a brownifh red, ftained with oblong fquares of white and ftabrilia, like ftriped taffaty. The ancient has very vivid colours; and the modern comes pretty near it.

MARBLE of *Siguan*, in the Pyrenean, is ordinarily of a greenifh brown, with red ftains; though this is fomewhat various in its colours.

MARBLE, *Thafium* MARMOR, in the *Writings of the Ancients*, a name given to a fpecies of *marble*, ufed in building. It had its name from the ifland Thafus, one of the Cyclades, where it was dug; it was of a duffy greyifh white, and feemed to be compofed of the fame matter with the common white *marbles*, with greyifh veins: only that the matter of the veins here did not run into thofe determinate parcels, but were blended among the whole mafs.

MARBLE of *Thin*, near Namur in Liege, is a pure black, foft, kind, and eafy to work, and receives a more beautiful polifh than thofe of Namur and Dinan.

MARBLE, *Thiburtinum* MARMOR, in the *Natural Hiftory of the Ancients*, the name of the green and white *marble*, common in tables, &c. at this time, and by our artificers called Egyptian *marble*.

The ancient Romans had it from Egypt, and we alfo have the fineft pieces thence; though the greater part of what we ufe is not brought quite fo far. Hill's Hift. of Foff. p. 481.

MARBLE *Bigio Nero*, or black grey, is antique.

MARBLE, *white-veined*, has large veins, with grey and blue ftains on a white ground. It comes from Carrara.

MARBLE, *white*, that dug out of the Pyrenæans, on the side of Bayonne, is inferior to that of Carrara, its grain being coarser, and shining, like a kind of salt. It is something like the ancient white Greek *marble*, whereof their statues were made; but it is not so hard or beautiful.

MARBLE, *ancient black and white*, is now very rare, its quarries being entirely lost; it is divided between a pure white and a bright black in lamine.

MARBLE, *blue Turquin*, is mixed with a dirty kind of white, and comes from the coast of Genoa.

MARBLE *Fior di Persico* comes from Italy. It consists of red and white stains, somewhat yellowish.

MARBLE, *yellow*, is a kind of yellow Isabella, without veins: it is antique, and now very rare.

MARBLE, *black antique*, is of a pure black, without stains, and softer than the modern black. There was some of it brought from Greece, called *marmor* LUCULLEUM; but this was not so much prized as that which the Egyptians brought from Ethiopia, approaching to an iron-colour, and called BASALTES, or the touch-stone, because it served them for a trial of metals.

MARBLE, *white and black*, has a pure black ground, with some very white veins.

MARBLE called *occhio di pavone*, or peacock's eye, is mingled with red, white, and bluish clouds, somewhat resembling the eyes at the end of a peacock's tail.

MARBLE, *green, antique*, is a mixture of grass-green and black, in clouds of unequal forms and bignesses; and is very rare, the quarries being lost.

MARBLE, *common modern green*, improperly called Egyptian, is brought from Carrara, on the coast of Genoa: it is of a deep green, spotted with grey.

MARBLE, *rapid*, is that which, being too hard, works with difficulty, and is liable to splinter, as the black of Namur.

MARBLE, *fibrous*, is that full of threads or filaments.

MARBLE, *brittle*, is that which crumbles under the instrument, as the white Greek *marble*, and that of the Pyrenæans, &c.

MARBLE, *stony*, that which has soft places in it, which must be filled up with cement, as that of Languedoc.

There are two defects frequent in *marble*, which augment the difficulty in cutting and polishing them; the one, what they sometimes call *nails*, answering to the knots in wood; the other, called *emeril*, is a mixture of mundic, or other minerals, forming black stains in the *marble*. The knots are common to all *marbles*; the emeril is peculiar to the white.

MARBLES, *artificial*. The stucco, whereof they make statues, bulls, basso-relievos, and other ornaments of architecture, ought to be *marble* pulverized, mixed in a certain proportion with plaister; the whole well sifted, worked up with water, and used like common plaister. See STUCCO.

There is also a kind of artificial *marble* made of the flaky selenites, or a transparent stone, resembling plaister; which becomes very hard, receives a tolerable polish, and may deceive a good eye. This kind of selenites resembles Muscovy tale.

There is another sort of artificial *marble*, formed by corrosive tinctures, which, penetrating into white *marble* to the depth of a line, or more, imitate the various colours of other dearer *marbles*.

There is also a preparation of brimstone in imitation of *marble*.

To do this, you must provide yourself with a flat and smooth piece of *marble*; on this make a border or wall, to encompass either a square or oval table, which may be done either with wax or clay. Then having provided several sorts of colours, as white-lead, vermilion, lake, orpiment, mafticot, smalt, Prussian blue, &c. melt on a slow fire some brimstone, in several glazed pipkins; put one particular sort of colour into each, and stir it well together; then having before oiled the *marble* all over within the wall, with one colour quickly drop spots upon it of larger and less size; after this, take another colour and do as before, and so on till the stone is covered with spots of all the colours you design to use. When this is done, you are next to consider what colour the mass or ground of your table is to be; if of a grey colour, then take fine sifted ashes, and mix it up with melted brimstone; or if red, with English red oker; if white, with white-lead; if black, with lamp or ivory black. Your brimstone for the ground must be pretty hot, that the coloured drops on the stone may unite and incorporate with it. When the ground is poured even all over, you are next, if judged necessary, to put a thin wainscot board upon it: this must be done whilst the brimstone is hot, making also the board hot, which ought to be thoroughly dry, in order to cause the brimstone to stick the better to it. When the whole is cold, take it up, and polish it with a cloth and oil, and it will look very beautiful. Smith's Laboratory, p. 228.

MARBLE, *colouring of*. The colouring of *marbles* is a nice art, and in order to succeed in it, the pieces of *marble* on which the experiments are tried, must be well polished, and clear from the least spot or vein. The harder the *marble* is, the better it will bear the heat necessary in the operation; therefore alabaster, and the common soft white *marble*, are very improper to perform these operations upon.

Heat is always necessary for the opening the pores of the *marble*, so as to render it fit to receive the colours; but the *marble* must never be made red hot, for then the texture of the *marble* itself is injured, and the colours are burnt, and lose their beauty. Too small a degree of heat is as bad as too great: for, in this case, though the *marble* receive the colour, it will not be fixed in it, nor strike deep enough. Some colours will strike, even cold, but they are never so well sunk in as when a just degree of heat is used. The proper degree is that which, without making the *marble* red, will make the liquor boil upon its surface. The menstruums used to strike in the colours must be varied according to the nature of the colour to be used. A lixivium made with horse's or dog's urine, with four parts quick-lime, and one part pot-ashes, is excellent for some colours; common ley of wood-ashes does very well for others: for some, spirit of wine is best; and finally, for others, oily liquors, or common white wine.

The colours which have been found to succeed best with the peculiar menstruums, are these: stone-blue dissolved in six times the quantity of spirit of wine, or of the urinous lixivium; and that colour which the painters call litmus, dissolved in common ley of wood-ashes. An extract of saffron, and that colour made of buck-thorn berries, and called by the painters sap-green, both succeed well dissolved in urine and quick-lime, and tolerably well in spirit of wine. Vermilion, and a fine powder of cochineal, succeed also very well in the same liquors. Dragon's blood succeeds very well in spirit of wine, as does also a tincture of logwood in the same spirit. Alkanet-root gives a fine colour, but the only menstruum to be used for this is oil of turpentine; for neither spirit of wine, nor any lixivium, will do with it. There is another kind of *sanguis draconis*, called dragon's blood in tears, which, mixed with urine alone, gives a very elegant colour. Phil. Trans. N° 268. or Abridg. vol. iv. part ii. p. 205.

Beside these mixtures of colours and menstruums, there are some colours which are to be laid on dry and unmixed. These are dragon's blood, of the purest kind, for a red; gamboge for a yellow; green wax for a green; common brimstone, pitch, and turpentine, for a brown colour. The *marbles*, for these experiments, must be made considerably hot, and then the colours are to be rubbed on dry in the lump. Some of these colours, when once given remain immutable, others are easily changed or destroyed. Thus the red colour given by dragon's blood, or by a decoction of logwood, will be wholly taken away by oil of tartar, and the polish of the *marble* not hurt by it.

A fine gold-colour is given in the following manner: take crude sal ammoniac, vitriol, and verdigris, of each equal quantities; white vitriol succeeds best, and all must be thoroughly mixed in fine powder.

The staining of *marble* to all the degrees of red, or yellow, by solutions of dragon's blood or gamboge, may be done by reducing these gums to powder, and grinding them, with the spirit of wine, in a glass mortar; but for smaller attempts, no method is so good as the mixing a little of either of these powders with spirit of wine, in a silver spoon, and *holding it over* burning charcoal. By this means a fine tincture will be extracted, and with a pencil dipped in this, the finest traces may be made on the *marble*, while cold, which, on the heating it afterwards, either on sand, or in a baker's oven, will all sink very deep, and remain perfectly distinct in the stone. It is very easy to make the ground-colour of the *marble* red or yellow by this means, and leave white veins in it. This is to be done by covering the places where the whiteness is to remain with some white paint, or even with two or three doubles only of paper, either of which will prevent the colour from penetrating in that part. All the degrees of red are to be given to *marble* by means of this gum alone; a slight tincture of it, without the assistance of heat to the *marble*, gives only a pale flesh-colour, but the stronger tincture give it yet deeper; to this the assistance of heat adds yet greatly: and finally the addition of a little pitch to the tincture gives it a tendency to blackness, or any degree of deep red that is desired.

A blue colour may be given also to *marble* by dissolving turnsol in a lixivium of lime and urine, or in the volatile spirit of urine; but this has always a tendency to purple, whether made by the one or the other of these ways. A better blue, and used in an easier manner, is furnished by

the Canary tartrifol, a fubſtance well-known among the dyers: this needs only to be diſſolved in water, and drawn on the place with a pencil; this penetrates very deep into the *marble*, and the colour may be increaſed by drawing the pencil wetted in freſh ſeveral times over the ſame lines. This colour is ſubject to ſpread and diffuſe itſelf irregularly; but it may be kept in regular bounds, by circumſcribing its lines with beds of wax, or any other ſuch ſubſtance. It is to be obſerved, that this colour ſhould always be laid on cold, and no heat given even afterwards to the *marble*: and one great advantage of this colour is, that it is therefore eaſily added to *marbles* already ſtained with any other colours, and it is a very beautiful tinge, and laſts a long time. Mem. Acad. Par. 1732.

This art has in ſeveral people's hands been a very lucrative ſecret, though there is leaſtwife any thing in it that has not at one time or other been publiſhed.

Kircher has the honour of being one of the firſt, who publiſhed any thing practicable about it. This author meeting with ſtones in ſome cabinets ſuppoſed to be natural, but having figures too nice and particular to be ſuppoſed to be nature's making, and theſe not only on the ſurface, but ſunk through the whole body of the ſtones, was at the pains of finding out the artiſt who did the buſineſs; and on his refuſing to part with the ſecret on any terms, this author with Albert Gunner, a Saxon, endeavoured to find it out; in which they ſucceeded at length very well. Their method is this: take aqua fortis and aqua regia of each one ounce, ſal ammoniac one ounce, ſpirit of wine two drams, about twenty-ſix grains of gold, and two drams of pure ſilver; let the ſilver be calcined and put into a vial, and pour upon it the aqua fortis; let this ſtand ſome time, then evaporate it, and the remainder will firſt appear of a blue and afterwards of a black colour: then put the gold into another vial, pour the aqua regia upon it, and when it is diſſolved evaporate it as the former; then put the ſpirit of wine upon the ſal ammoniac, and let it be evaporated in the ſame manner. All the remainders and many others made in the ſame manner from other metals diſſolved in their proper acid menſtrua, are to be kept ſeparate and uſed with a pencil on the marble. Theſe will penetrate without the leaſt aſſiſtance of heat, and the figure being traced with a pencil on the *marble*, the ſeveral parts are to be touched over with the proper colours, and this renewed daily till the colours have penetrated to the deſired depth into the ſtone. After this the maſs may be cut into thin plates, and every one of them will have the figure exactly repreſented on both ſurfaces, the colours never ſpreading: the neateſt method of applying theſe, or the other tinging ſubſtances, to *marble* that is to be wrought into any ornamental work, and where the back is not expoſed to view, is to apply the colours behind, and renew them ſo often till the figure is ſufficiently ſeen through the ſurface on the front, though it does not quite extend to it. This is the method that of all others brings the ſtone to a nearer reſemblance of natural veins of this kind.

The ſame author gives another method to colour *marble*, by vitriol, bitumen, &c. forming a deſign of what you like upon paper, and laying the ſame deſign between two pieces of poliſhed *marbles*; then cloſing all the interſtices with wax, you bury them for a month or two in a damp place. On taking them up, you will find, that the deſign you painted on the paper, has penetrated the *marbles*, and formed exactly the ſame deſign on them. Kircher's Mund. Subter. lib. viii. § 1. cap. 9.

Wallerius, in his Mineralogy, vol. ii. p. 128. recommends the laſt method of Kircher; and the firſt method is copied in the Phil. Tranſ. № 7.

The art was practiſed by Mr. Bird, a ſtone-cutter at Oxford, before the year 1666; but his method is not recorded. Mr. Robert Chambers, of Minching Hampton, in Glouceſterſhire, diſcovered and practiſed a method of colouring *marble*, which he kept a ſecret. Mr. Da Coſta has publiſhed an account of experiments made on ſeveral pieces of *marble*, ſtained by this artiſt. Phil. Tranſ. vol. li. art. 5. p. 30, &c.

Spots of oil ſtain white *marble*, ſo that they cannot be taken out. See STAINING *of Stones*.

MARBLE, *poliſhed*, is that, which, being well rubbed with free-ſtone, and afterwards with pummice-ſtone, is at laſt poliſhed with emery, if the *marble* be of ſeveral colours; and with calcined tin, if it be white. In Italy, they poliſh with a piece of lead and emery.

There are various ways of poliſhing *marble*: ſome lay three or four blocks in a row, and with another, fixed to a broad beetle, and an handle fixed at oblique angles, with ſand and water between, work the upper ſtone backwards and forwards on the lower ones, till the ſtrokes of the ſaw are worn off; after which, they poliſh them with emery and putty.

MARBLES, *Arundel*. See ARUNDELIAN *marbles*.

MARBLE-*colour*. To give this variegated colour to glaſs is a very eaſy operation: there needs no more than to put cryſtal-frit into a pot in the furnace, and to work it before it has ſtood the uſual time to putrify in the fire. Neri's Art of Glaſs, p. 99.

MARBLE-*wood*, a name given by the people of ſome parts of America to the *lignum rhodium*, or role-wood, from the heart of the tree being ſometimes variegated like *marble*.

MARBLED, ſomething veined, or clouded, reſembling marble. *Marbled paper* is a paper ſtained with various clouds and ſhades, reſembling, in ſome meaſure, the divers veins of marble; the method of making which, ſee under PAPER.

MARBLED *China-ware*, a name given by many to a ſpecies of porcelain or China-ware, which ſeems to be full of cemented flaws. It is called by the Chineſe, who are very fond of it, *ſſa-tchu*.

It is generally plain white, ſometimes blue, and has exactly the appearance of a piece of China which had been firſt broken, and then had all the pieces cemented in their places again, and covered with the original varniſh. The manner of preparing it is eaſy, and might be imitated with us. Inſtead of the common varniſh of the China-ware, which is made of what they call oil of ſtone and oil of ſern mixed together, they cover this with a ſimple thing made only of a ſort of coarſe agates, calcined to a white powder, and ſeparated from the groſſer parts by means of water, after long grinding in mortars. When the powder has been thus prepared, it is left moiſt, or in form of a ſort of cream, with the laſt water that it ſuffered to remain in it, and this is uſed as the varniſh. Our cryſtal would ſerve full as well as theſe coarſe agates, and the method of preparation is perfectly eaſy. Obſerv. ſur les Cout. de l'Aſie.

The occaſion of the ſingular appearance of this ſort of porcelain is, that the varniſh never ſpreads evenly, but runs into ridges and veins. Theſe often run naturally into a ſort of moſaic-work, which can ſcarce be taken for the effect of chance. If the *marbled* China be deſired blue they firſt give it a general coat of this colour, by dipping the veſſel into a blue varniſh; and when this is thoroughly dry, they add another coat of this agate-oil.

MARBLES, *ſtoping*, are moſtly imported from Holland; where it is ſaid they are made by breaking the ſtone alabaſter, or other ſubſtance, into pieces, or chips of a ſuitable ſize; theſe are put into an iron-mill which turns by water: there are ſeveral partitions with raſps within, cut ſideways, not with teeth, which turn conſtantly round with great ſwiftneſs: the friction againſt the raſps makes them round, and as they are formed, they fall out of different holes, into which ſize or chance throws them. They are brought from Nuremberg to Rotterdam, down the Rhine, and from thence diſperſed over Europe.

MARBLING, the art or act of painting or diſpoſing colours in ſuch a manner, that they may repreſent marble. Thus we *marble* books, paper, wood, &c. See PAPER, and *Coloring*, &c. of BOOKS.

MARBLING *of books*, among *Bookbinders*, denotes the ſprinkling over the cover of a book firſt with ink, and afterwards with weak aquafortis. See BOOK-*binding*.

They alſo *marble* books on the edges; but, in this *marbling*, there is no black uſed, but in lieu thereof, red, blue, &c.

MARCASITE, MARCALITA, a ſort of metallic mineral, ſuppoſed by many to be the ſeed or firſt matter of metals. On this principle, there ſhould be as many different *marcaſites* as metals; which is alſo ſaid to be true in effect, the name being applied by ſome to every mineral body that has metallic particles in its compoſition, though not enough to make it worth working; in which caſe it would be called *ore*.

There are only three kinds in the ſhops, which are called *marcaſite* of gold, of ſilver, and of copper; though ſome repute the laſt alone to be a *marcaſite* of iron; biſmuth, *marcaſite* of tin; and zinc, or ſpelter, *marcaſite* of lead: but this we leave to the chemiſts.

Marcaſite of gold is found in little balls or nodules, about the bigneſs of nuts, nearly round, heavy, of a brown colour without. *Marcaſite* of ſilver is like that of gold, only paler coloured within, the colour differs much, the one having a gold-colour and the other a ſilver-colour, both ſhining and brilliant. The *marcaſite* of copper is about the bigneſs of a ſmall apple, round or oblong, brown without, yellow and ſtriated within, brilliant and ſhining.

Marcaſites are found in mines of metals; they all contain ſulphur, and a vitrioline ſalt, eſpecially that of copper; ſome of them alſo contain antimony and biſmuth.

This name is uſed in a very vague ſenſe by many writers upon foſſils, but is by ſome reſtrained to a peculiar genus of foſſils, the characters of which are, that they are compound inflammable metallic bodies, naturally conſtituting whole ſtrata; of a ſolid and firm conſiſtance, of an obſcurely and irregularly foliaceous ſtructure, and of a bright glittering appearance, very freely and readily giving fire with ſteel, not fermenting with acid menſtruums,

flimums, and when put into the fire, yielding a deep blue flame, and finally calcining into a purple powder.

Though the natural difpofition of thefe bodies be to form whole ftrata, and they are moft ufually found in this ftate, yet they are at times found in loofe maffes, as many, even of the ftones of ftrata, at times are. They are fubject alfo, by their frequent admixture with adventitious matter, the ores of metals, and other foffile bodies, to fuch various external appearances, that their varieties are almoft innumerable, and moft of them are very beautiful: but though thefe accidental differences are fo very numerous, the genuine fpecies are very few, the naturalift obferving only three: thofe are, 1. The bright filver colourrd *marcaffite*. 2. The bright gold-colored *marcaffite*. And 3. The pale heavy dead white *marcaffite*.

The firft fpecies ufually conftitutes ftrata of great extent, and of about a foot in thicknefs; very often much lefs, but fcarce ever much more: it is compofed of a number of foliaceous flakes, not regularly difpofed, but oddly contorted and waved, and often folding round one another; though fometimes this ftructure is lefs diftinct, and the whole feems run into one folid mafs: its colour is extremely bright, very like filver, but more glittering. This is its common and its more pure ftate; but it is liable to a vaft number of varieties. Sometimes it contains a large quantity of the ore of lead or tin; and very often a duiky brown ferruginous matter is intimately mixed with it; at other times many of the angular and regularly figured phlogonitæ are immerfed in it, and feem to make a part of its very ftructure; and fometimes where it has room, its conftituent flakes rife on its furface in feveral conjunct ferics, and form a very elegant foliaceous top to it. Nor is this all the difference of appearance it puts on; for very often, where there has not been a fufficient quantity of it to form itfelf into any figure alone, it is found depofited in fparks, or flat cakes, of a more or lefs complex, but always of a flaky ftructure, on ftones or ores of various kinds; and frequently, befide its native filvery white, it has all the rainbow colours on its different parts, as differently turned to the light. The *golden marcaffite* is a more beautiful fubftance than the former: it is of a lefs firm or compact ftructure than the others, and is ufually found in very long but very thin ftrata, and is of an extremely bright and glittering appearance, and is fometimes found in large and mif-fhapen nodules, or loofe maffes. It is liable to all the accidental varieties that the former is, and in many of them makes a very elegant appearance.

The third, or dead white kind, is the hardeft and heavieft of all: it is, in its more ufual and natural appearance, of much lefs beauty than the former kinds, but it is, like them, fubject to various accidents, under fome of which it makes a very gay and fplendid appearance: it, like the reft, fometimes forms complete ftrata, fometimes detached nodules; but its moft ufual appearance is in the horizontal cavities of other ftrata; in thefe it often forms a fort of ball-ftratum of many yards continuance, and frequently of very conliderable thicknefs, for it almoft always fills up the whole vacuity, and that fo clofely as feldom to leave room for any foliaceous fhoots at its furface, or protuberances at its edges, but forms a plain mafs like that of a metal melted and poured into the place; it in the fmoothefl furface of all the *marcaffites*, and is fomewhat foft to the touch, and in colour refembles tarnifhed pewter.

This is its common appearance, but it fometimes fhews itfelf like the reft in fmall patches on the furfaces of ftones, and is there often very beautifully foliated; it is liable alfo to all the accidents of the other kinds.

The *marcaffites* are all found in great plenty in the Engliih and German mines. Devonfhire and Cornwall afford vaft quantities of them; and very beautiful ones are found in Derbyfhire. They often contain the feveral metals, but the quantity of fulphur has yet baffled all the attempts that have been made to work them to advantage. Hift Hift. of Foff. p. 619.

Ariceuna mentions four kinds of *marcaffite*; the golden, the filvery, the braffy, and the iron *marcaffite*. He does not pretend that the two firft contain really the metals whofe names they bear, but fays they are fo called from their likenefs in colour, and that they are thought by fome to poffefs, in part, their virtues. Diofcorides mentions only one kind, that is, the braffy pyrites or *marcaffite*. This is, of all others, the moft common; and the preference is given by this author to fuch of it as is of a bright braſs-colour, and fuch as, when ſtruck againſt ſteel, yields the largeſt ſparks. This is the kind called by Avicenna and Serapion, *marcaſita aurea*, and it is called by the Perſians, *ſapar aſtraneuſi*, that is the ſtone of light or brightneſs, there being a very vivid and ſparkling luſtre in this ſtone when newly broken. The ancients uſed to calcine it, and then made it an ingredient in their ſeveral compoſitions for diſeaſes of the eye. The calcining it renders it a ſort of coleothar of vitriol, for the ſulphureous parts burn away in the operation, and leave only the *caput mortuum* of the vitriol behind; ſome have ſuppoſed it called *lapis hæræ*, from its reſtoring light to the eyes; but this is a very far-fetched etymology.

The firſt opinion of the world, in regard to this glittering ſubſtance, was, that it was almoſt all gold or ſilver, according to the colour: but the error of this opinion being ſoon diſcovered by trial, there roſe another contrary one, that *marcaſite* never contained any metal at all. This is, in general, true of our *marcaſites*, but it is not to be extended into a general rule for thoſe of all the world. The ſearchers after royal mines are not to throw away all theſe ſubſtances as uſeleſs, wherever they find them: for Alonſo Barba, a very great judge of theſe things, and himſelf very converſant in mines, aſſures us, that the *marcaſitas* of the mines of Moncerrat en los Chicas contain uſually one half ſilver: and in the mines of Potoſi there is great plenty of a *marcaſite*, in which there is ſometimes a large quantity of the black ſilver-ore, well known there, and eſteemed one of the richeſt kinds, except the native ſilver. They always are glad to find this *marcaſite* vein, it being eſteemed a proof that the black ore is very rich in ſilver; they make the ſame ſort of obſervation in regard to orpiment and gold, that they do in regard to *marcaſite* and ſilver; that the orpiment uſually contains itſelf ſome gold, and is a certain ſign that there is gold in the neighbourhood wherever it is found. Alonſo Barba, de Met. This name, ſays the author of the Dictionary of Chymiſtry, has long been given indifferently to all ſorts of minerals, to ores, pyrites, and to ſemi-metals: lately it ſeems to be confined to PYRITES; and Wallerius propoſes to apply it only to ſuch pyrites as are regularly formed.

MARCELLIANISM, the doctrines and opinions of the *Marcellians*, a ſect of ancient heretics, towards the cloſe of the ſecond century, ſo called from *Marcellus* of Ancyra, their leader, who was accuſed of reviving the errors of Sabellius.

Some, however, are of opinion, that *Marcellus* was orthodox, and that they were his enemies the Arians, who fathered their error upon him. St. Epiphanius obſerves, that there was a great deal of diſpute with regard to the real tenets of *Marcellus*; but that, as to his followers, it is evident they did not own the three hypoſtaſes: for *Marcellus* conſidered the Son and Holy Ghoſt, as two emanations from the divine nature, which, after performing their reſpective offices, were to return again into the ſubſtance of the Father: and this opinion is altogether incompatible with the belief of three diſtinct perſons in the Godhead.

MARCGRAVE, or MARGRAVE, a kind of dignity in Germany, anſwering to our MARQUIS.

The word is derived from the German *marck*, or *mark*, which ſignifies *a frontier*, formed, as Junius conjectures, from the laſt ſyllable of the Greek ακρωτηριον, which ſignifies both a *mark*, and a *limit*; and *graffe*, *count*, *governor*; *margraves* being originally governors of cities lying on the frontiers of a country or ſtate.

MARCGRAVIA, in *Botany*, a genus of the *polyandria monogynia* claſs: the characters of which are, that the corolla has a ſingle petal, and is calyptriform; the calyx is ſix-leaved, and imbricated; and the fruit is a berry, conſiſting of many cells, and containing many ſeeds. There is only one ſpecies.

MARCH, MARTIUS, the third month of the year, according to the common way of computing.

Among the Romans, *March* was the firſt month; and, in ſome eccleſiaſtical computations, that order is ſtill preſerved; as particularly in reckoning the number of years from the incarnation of our Saviour, which is done from the 25th of *March*.

In England, (before the alteration of the ſtyle) *March*, properly ſpeaking, was the firſt month in order, the new year commencing from the 25th; though, in compliance to the cuſtoms of our neighbours, we uſually ranked it as the third; but, in this reſpect, we ſpoke one way, and wrote another.

Till the year 1564, the French reckoned the beginning of their year from Eaſter; ſo that there were two months of *March* in one year, one of which they called *March before Eaſter*, and the other *March after Eaſter*, and, when *Eaſter* fell within the month of *March*, the beginning of the month was in one year, and the end in another.

It was Romulus who divided the year into months: to the firſt of which he gave the name of his ſuppoſed father *Mars*. Ovid, however, obſerves, that the people of Italy had the month of *March* before Romulus's time; but that they placed it very differently, ſome making it the third, ſome the fourth, ſome the fifth, and others the tenth month of the year.

In this month it was that the Romans ſacrificed to Anna

Perenna; that they began their comitia; that they adjudged their public farms and leases; that the mistresses served the slaves and servants at table, as the masters did in the Saturnalia; and that the Vestals renewed the sacred fire.

The month of *March* was always under the protection of Minerva, and always consisted of thirty-one days. The ancients held it an unhappy month for marriage, as well as the month of May.

MARCH, in *Military Language*, is in general the motion of a body of men from one place to another.

But the beat of the drum, when the soldiers are upon *march*, or beginning to *march*, is likewise called the *march*. It is likewise a word of command, when a battalion is to alter its disposition.

As many accidents may happen in the *march* of an army, from defiles, marshes, woods, and the like, it is the prudence of a general to order his *march* accordingly, and to take care that the columns of his army have a free communication one with the other. The *march* of an army is composed of an advance guard, the main body, and the rear guard, and is sometimes in two, four, six, or eight columns, according as the ground will allow.

MARCHANTIA, in *Botany*, a genus of the *cryptogamia* class of plants, and of the order of *algæ*: the characters are, that it has male and female flowers on different parts of the same plants; the male flower stands on a long erect pedunele; the cup is a common perianthium of the peltated kind, divided into several segments, and containing under it as many flowers as there are segments; each flower is monopetalous, of a turbinated form, standing erect, and somewhat shorter than the cup; having a single stamen, which is a slender filament, longer than the flower; the anthers is oval, and commonly found burst at the top into as many parts as there are segments in the perianthium; the female flower has no pedicle; the cup is a single-leaved perianthium, sessile, campanulated, and polyspermous. There are seven species.

MARCHES, *marchia*, from the German, *march*, i. e. *limes*, or from the French *marque*, viz. *signum*, being the notorious distinction between two territories, are the limits between England and Wales, or Scotland; which last are divided into west and middle *marches*. 4 H. V. cap. 7. 23 Edw. IV. cap. 8. 24 H. VIII. cap. 9. And there was formerly a court, called the court of the *marches* of Wales, where pleas of debt or damages, not above the value of 50*l.* were tried and determined; and if the council of the *marches* held plea for debts above that sum, &c. a prohibition might be awarded.

MARCHERS, or *Lords* MARCHERS, in our *Old Writers*, noblemen that lived on the marches of Wales, or Scotland. These, in times past, according to Camden, had their laws, and power of life and death, &c. like petty kings. But such powers were abolished by the stat. 27 Hen. VIII. cap. 27. and 1 Edw. VI cap. 10.

MARCHESVAN, in *Chronology*, the eighth month of the Jewish ecclesiastical year, answering to part of our October and November.

MARCHET, or MARCHETTA, a pecuniary fine, anciently paid by the tenant to his lord, for the marriage of one of the tenant's daughters.

This custom obtained, with some difference, throughout all England and Wales, as also in Scotland; and it still continues to obtain in some places. According to the custom of the manor of Dinover in Carmarthenshire, every tenant, at the marriage of his daughter, pays ten shillings to the lord; which, in the British language is called *gwabr-merched*, i. e. *maid's fee*. See AMABYR.

In Scotland, and the north parts of England, the custom was, for the lord to lie the first night with the bride of his tenant; but this usage was abrogated by king Malcolm III. at the instance of his queen; and, instead thereof, a mark was paid by the bridegroom to the lord: whence it is called *marcheta mulieris*. See BOROUGH-*English*.

MARCHIONIS *pulvis*, a term used for a certain compound powder, prescribed in the Leyden Dispensatory, and greatly recommended by many as an anti-epileptic and absorbent.

The ingredients are male piony-root, half an ounce, wood of misletoe of the oak, raspings of ivory, elks hoof, spodium, the roots of the unicorn-fish, or, in its stead, the antlers of the stag's horn, red and white coral, and pearls, of each a dram. These are all to be rubbed into a powder, with twenty leaves of pure gold, and given half a dram twice a day.

MARCIONITES, or MARCIONISTS, MARCIONISTÆ, a very ancient and popular sect of heretics, who, in the time of St. Epiphanius, were spread over Italy, Egypt, Palestine, Syria, Arabia, Persia, and other countries: they were thus denominated from their author *Marcion*. *Marcion* was of Pontus, the son of a bishop, and at first made profession of the monastical life; but he was excommunicated by his own father, who would never admit him again into the communion of the church, not even on his repentance. On this, he abandoned his own country, and retired to Rome, where he began to broach his doctrines.

He laid down two principles, the one good, the other evil: between these they imagined an intermediate kind of deity of a mixed nature, who was the creator of this inferior world, and the god and legislator of the Jewish nation: the other nations, who worshipped a variety of gods, were supposed to be under the empire of the evil principle. These two conflicting powers exercise oppressions upon rational and immortal souls; and, therefore, the supreme God, to deliver them from bondage, sent to the Jews a being more like unto himself, even his son Jesus Christ, clothed with a certain shadowy resemblance of a body: this celestial messenger was attacked by the prince of darkness, and by the god of the Jews, but without effect. Those who follow the directions of this celestial conductor, mortify the body by fastings and austerities, and renounce the precepts of the god of the Jews, and of the prince of darkness, flesh, after death, ascend to the mansions of felicity and perfection. The rule of manners which *Marcion* prescribed to his followers, was excessively austere, containing an express prohibition of wedlock, wine, flesh, and all the external comforts of life. See MANICHÆANS.

Marcion denied the real birth, incarnation, and passion of Jesus Christ, and held them to be all apparent only. He denied the resurrection of the body; and allowed none to be baptized, but those who preferred their continence; but these, he granted, might be baptized three times.

In many things, he followed the sentiments of the heretic Cerdon, and rejected the law and the prophets. He pretended, the gospel had been corrupted by false prophets, and allowed none of the evangelists, but St. Luke, whom also he altered in many places, as well as the epistles of St. Paul, a great many things in which he threw out. In his own copy of St. Luke, he threw out the two first chapters entire.

MARCITES, MARCITÆ, a sect of heretics in the second century, who also called themselves the *perfecti*, and made profession of doing every thing with a great deal of liberty, and without any fear.

This doctrine they borrowed from Simon Magus, who, however, was not their chief; for they were called *Marcites* from one *Marcus*, who conferred the priesthood, and the administration of the sacraments, on women.

MARCOSIANS, or COLORBARSIANS, an ancient sect in the church, making a branch of the VALENTINIANS. St. Irenæus speaks at large of the leader of this sect, *Marcus*, who it seems, was reputed a great magician.

The *Marcosians* had a great number of apocryphal books, which they held for canonical, and of the same authority with our's. Out of these they picked several idle fables touching the infancy of Jesus Christ, which they put off for true histories. Many of these fables are still in use and credit among the Greek monks.

MARCULUS, among the Romans, a knocker, or instrument of iron to knock at the doors with.

MARDAC, in the *Materia Medica of the Ancients*, a name given by some to litharge. The Arabian writers have sometimes called it by this name, and sometimes by that of *mardesengi*. Many of their commentators have thought that they meant two different substances by these two names; but it does not appear to be truly the case, the two words standing, in different writers, for the same thing. Avicenna has given us a chapter on *mardac*, in which he has translated the chapter of Dioscorides on litharge: and Serapion has given us a chapter on the *mardesengi*, in which he has given us an account of the same substance, under the terms that Galen uses for the descriptions of litharge, and even quotes him for the account.

MARDAITES, in *Ecclesiastical History*. See MARONITES.

MARE, *equa*, in *Zoology*, the female of the HORSE kind.

No *mares* in the world are better for breeding than the English, provided they are properly chosen for the sort of horse intended to be bred. The *mare*, whatever sort of horse is intended to be raised from her, should be perfectly sound, and as free from all defects as the stallion. They should have no splaint, spavin, nor curb about them; for the colt will certainly take after them, if they have. The highest spirited mares are best, and, in general, if there be any natural defect in the *mare*, it should be remedied in the stallion; and if any in the stallion, it should be remedied in the *mare*, as much as possible, in order to the having good colts.

The particular directions regarding the kinds of horses to be bred, are these: if for the manege, or pads, the *mare* should have their heads well set on, and their breasts broad;

broad; their legs not too long, their eyes bright and sparkling, and bodies large enough, that the foal may have room to lie in their belly. They should be of a good and gentle disposition, and their motions easy and graceful: the more good qualities the *mares* have, the better, in general, the colts will prove.

If the owner would breed for racing, or for hunting, the *mares* must be chosen lighter, with short backs and long sides; their legs must be longer, and the breast not so broad; and such should always be chosen as have good blood in their veins. If the speed and wind of any particular *mare* have been tried, and found good, there is the more certainty of a good colt from her: but she should be in full health and vigour at the time, and not above seven years old, or eight at the utmost. The younger the breeders are, the better, in general, the colts will be.

A *mare* may be covered any time after she is three years old; but the best time is after she is four; at this age, or between this and seven, she will nourish a colt best of all; and though she will breed till she is thirteen, yet it is generally observed, that when she is past ten, the colts bred from her are dull and heavy. People who regard the moon, in these cases, will have their *mares* covered only between the end of the first quarter and the full; they presume that these colts will be the most strong and vigorous; but that these beget in the waning of the moon, will always be weakly and tender. A much more essential caution, however is, that before the *mare* is to be covered, she should be taken into the house for six weeks, at least, and fed well with good hay and oats, well sifted, to give her strength to go through the operation. If there is any reason to suspect that the *mare* will not conceive, the best method to insure it is to let her blood in the neck, about six days before she is covered: the quantity of blood taken away should be about two quarts, or somewhat less. It is a general caution to open the veins on both sides the neck for this, taking half the quantity from each, but this is trifling.

The method of covering, so as to make it most sure to succeed, is this: the *mare* is to be brought into some open place, and tied to a post; and the stallion is to leap her in the morning fasting, and as soon as he dismounts, a pail of cold water is to be thrown upon her, to make her shrink in and retain the seed. She is then to be taken away out of hearing of the horse, and is neither to eat nor drink for four or five hours after.

It may be known if the stands to her covering, by her keeping a good stomach, and not neighing at the sight of a horse. Some, to make it quite secure, put the *mare* and horse together in an empty house every night, for four or five nights, taking away the horse in the morning, and feeding him very liberally, and the *mare* very sparingly, and particularly giving her very little water.

There must be proper care taken of her after covering; the same method of feeding her with good hay, and sifted oats, must be continued three weeks or a month, and the must be kept within doors, and without any exercise; her stable must be kept very clean, and her feet pared, and with thin shoes on. After this she may be turned out for the summer season, and only taken up in September, in order to be kept well fed till the foals. If there be great difficulty in her fosling, or the secundine be retained, the method is to hold her nostrils, so that she cannot breathe; and if this does not do, a decoction of madder-root, or of fennel, in water, with a mixture of ale or wine, is found very effectual.

When the whole is over, the *mare* is very apt to eat up her secundine; but this should be prevented, for it is an unnatural food for her, and will injure her health. When she has licked her foal, some persons should streak and milk her before the foal sucks. This will make the milk come down in greater plenty, and will prevent it from clotting into lumps, or from disagreeing with the young creature's stomach. It often happens, that the milk clods in the udder, and the foal, being able to get none out, the *mare* is supposed to be dry, and in consequence of this supposition, she actually becomes so. But the remedy is easy: let as much milk as can be got from her be boiled with some lavender-flowers, and the udder bathed thoroughly with it warm, several times a day: if no milk, or not enough can be obtained from her, other milk or common water will do; for the principal effect is from the heat of the liquor, and the virtue of the lavender, which breaks the clods and lumps, and then the foal's sucking more as it grows stronger, will prevent the like accident for the future.

The water given the *mare* for the first month after foaling, must be what the dealers in horses call the white mash, that is, bran and water, stirred together till the liquor is white: a month after foaling a decoction of brimstone and farin will be very proper, and will give strength to the colt.

After this the *mare* may be put to any moderate exercise, as harrowing or the like, and both she and the colt will be the better for it; only care is to be taken that she do not let the colt suck while she is hot.

Many are of opinion, that the winter is a very bad time for a *mare* to be foaling; but though there is scarcity of grass, the *mare* may be housed at this time, and well fed with hard meat, and, in this case, it will prove better both for her and the colt; he will be better limbed and stronger than if bred at grass. See FOAL.

MARECA, in *Ornithology*, the name of a Brasilian species of duck, much valued there at table. It is of the shape of our duck; its head is grey, but has a beautiful red spot on each side, at the insertion of the beak, and a whiteness in the lower part under the eyes; its breast and belly are of the colour of fresh cut oak, variegated with black spots; its legs and feet are black; its tail grey; and its wings elegantly variegated with grey and brown; but they have in the middle a large mixture of that glossy green, which we see in the necks of our drakes. There is besides this, another species of the *mareca*, which is of a dusky olive-coloured brown on the back, white on the throat, and grey on the breast and belly, and very remarkable for the fine bright red colour of its feet.

MARENA, in *Ichthyology*, the name of a fish of the haringform kind, much approaching to the nature of the common pilchard; but differing from it in that it has not the serrated longitudinal line under the belly, and lives in lakes, not in the ocean. It seldom arrives to more than five inches in length; its back is blackish, and its sides white and silvery, and its scales are very loose, and easily rubbed off. It is a better tasted fish than the pilchard, and its flesh is firmer.

MARGA, *marle*. See MARLE.

MARGARITÆ. See PEARLS.

MARGARITINI are glass ornaments, made at Venice of small glass tubes of different colours, which are blown at Murano, and which the women of the lower class wear about their arms and necks. The largest sort are used for making rosaries. This work is performed with great dispatch, the artisan taking a whole handful of those tubes at once, and breaking them off one after another with an iron tool. Those short cylinders are mixed with a kind of ashes, and put over the fire in an iron pan; and when the two ends begin to melt, by stirring them about with an iron wire, they are brought to a round figure; but care is taken not to leave them too long over the fire, lest the hole through which they are to be strung, should be entirely closed by the melting of the glass. There are several streets at Francisco di Vigna, entirely inhabited by people, whose sole occupation is to make and string these *margaritini*. Keyller's Travels, vol. iii. p. 301.

MARGEN, in the *Materia Medica*, a name used by some of the later Greek writers, to express red coral. It is founded on an error, however, the word *margen* being made from the Arabian *margian*, which does not signify coral, but a purple seaweed, or fucus, used in dying. See MARGIAN.

MARGENSTEIN, in *Natural History*, a name given by the German writers to a sort of indurated marle, which while in the strata, is nearly of the hardness of stone, but when laid on the surface of the earth, and exposed to the wind and rain, soon dissolves, and enters the pores of the ground, enriching the soil to a very great degree.

We have the same sort of stony marle in some parts of England, only that our's is less hard, and yet takes more time to break and dissolve in the air. They are both most proper for lands of a loose loamy nature, and keep them in heart a long time.

MARG-GRAVE. See MARGRAVE.

MARGIAN, in *History*, a name given by some of the ancient writers, particularly, the Arabian physicians, to the plant called by others *argema*, or *argimon*. This is described to be a purple sea-plant. Some have supposed that cochineal was meant by this word, but that is an error. Others have come somewhat nearer, in supposing it to be the name of coral; but as the ancients have said that it was used in dying, it could not be coral; and indeed there is no other plant that it can mean, but that fucus used by the Greeks in dying, and called *fucus porphyreus*, or the purple-dying sea-plant.

MARIA *Æg.* See AVE MARIA.

MARIENG-*glass*, in *Natural History*, a species of crystal, chiefly found in Russia, where, on account of its transparency, it is used for window-panes. It is a particular species of stone, lying in strata or flakes, like so many sheets of paper, and as easily separated. It is also called *shenglass*, and *ryssglass*.

MARIGOLD, in *Botany*. See MARYGOLD.

MARINE *barometer*. See BAROMETER.

MARQUES *de lodes*, in the *Mintage*. See DUEL.

MARINE-*chair*, is a contrivance of Mr. Irwin, for facilitating the neceſſary obſervations, in order to determine the LONGITUDE at ſea. It is ſaid that Mr. Irwin, on a trial of this machine, found the longitude within twenty-three miles, or about one-third of a degree.

MARINE *remains*, a term uſed by many authors to expreſs the ſhells of ſea-fiſhes, and parts of cruſtaceous and other ſea-animals, found in digging at great depths in the earth, or on the tops of high mountains. Their being lodged in theſe places, is an evident and unqueſtionable proof of the ſea's having once been there, ſince it muſt have covered theſe places where it has left its productions. It has been a favourite ſyſtem with many, and particularly with the late Dr. Woodward, that all theſe *marine* bodies were brought to the places where they now lie, by the waters of the univerſal deluge; which, as we are informed by holy writ, covered the whole ſurface of the globe, and even the higheſt mountains. But though this is a very ready expedient to account for many of the natural phenomena, yet there are evident proofs that it cannot have been the cauſe of all that is attributed to it; and there muſt neceſſarily have been ſome other cauſe of many of theſe remains having been placed where we now find them. Neither does the opinion of ſome particular authors, that partial inundations of different places have left theſe *marine* bodies behind them at the receſs of the waters, ſeem ſufficient to account for the multitudes of theſe remains, many of which we find thrown upon places inacceſſible to ſuch floods. Moro, de Cruſtaceis in Montib. deprehenſ.

Signior Moro has attempted to account for theſe phenomena on a new plan of reaſoning. He obſerves, that it is the beſt baſis of argument to begin from facts; and that if we can certainly find how ſome part of theſe animal remains came to be depoſited at ſuch great diſtances from their natural reſidence, we may very rationally conclude, that by the ſame means, be they what they will, all the reſt were alſo brought thither. He adds, that the earth, once the bottom of the ſea, or the level ſurface of a plain, may be, and frequently has been, in the memory of man, raiſed up into a mountain by ſubterranean fires, earthquakes, and volcanos. He mentions the famous inſtance of the new iſland raiſed out of the bottom of the ſea near Santorini in the year 1707, which became of a circumference not leſs than ſix miles, and of the new mountain raiſed near Puzzoli in 1538.

Theſe, and many other like facts, prove that the origin of mountains and iſlands may have been ſuch, and that the matter they conſiſt of may have been the ſame with what was once the bottom of the ſea; and that the *marine* bodies found in theſe mountains, were ſuch as were living, or remaining of living fiſh at the time when the iſlands or mountains were ſo raiſed above the ſurface of the water which before covered it.

This is no new opinion; but this author has ſet it in a new and much ſtronger light than it ever had appeared in before, by the inſtances and examples he has brought in proof of it. Some have been fond of believing that the bodies we call *marine remains*, were never indeed any parts of living animals, but that they are mere *lusus naturæ* formed in the places where they are found; but Fabius Columna proved this to be an error, ſhewing that the ſhark's teeth, or glоſſopetræ of the iſland of Malta, when calcined by a ſtrong fire, yielded aſhes the ſame with thoſe from animal bodies, and by no means of the ſame nature with thoſe produced from calcined ſtones.

That changes of parts of the bottom of the ſea into dry land, have often been made, is proved not only from the late known inſtances, but from the teſtimonies of Strabo, Pliny, and other writers of credit; and nothing is more obvious to reaſon, than that in the ſudden riſe of ſuch parts of the bottom of the ſea, all its contents, all the ſhells, and other hard parts of fiſhes lying there, would be carried up with it.

As ſome mountains and ſome iſlands muſt have certainly been produced in this manner, it is not impoſſible but that all of them may have been ſo; and there is no more than this required to account clearly and evidently for all the vaſt profuſion of *marine* bodies at land as we find them, without having recourſe to the improbable means of the univerſal deluge, which for many plain reaſons cannot have been the cauſe; or to the effects of particular inundations, which muſt have been wholly incapable of lodging many of them there. The lodgment of ſhells in the ſolid ſtrata of mountains, is better accounted for by this ſyſtem of ſignior Moro than any other: and if it be aſked why ſome mountains afford them in great plenty, and others not at all, it will not be difficult to anſwer, by obſerving, that among the mountains of the more known parts of the world, ſome conſiſt of mere ſolid rock, and others of various ſtrata of earthy and other matter; that the firſt of theſe may be ſuppoſed primary or natural mountains, and the others ſecondary or accidental ones; and that theſe *marine remains* are always wanting in the former, and uſually are found in the latter, which is a fact greatly favourable to this ſyſtem.

There are many difficulties attending the accounts of all authors of the formation of the earth, and the lodging theſe bodies in it; nor is this laſt ſyſtem without difficulty. The cauſes here alleged as to the origin of mountains and iſlands, doubtleſs have been ſo in regard to ſome, but ſcarce to all; and the bodies here treated of are ſo numerous, in ſome particular places, that ſcarce any account can ſolve the difficulty of their being collected together in ſo ſtrange a manner. *See Addenda*] FOSSILS.

MARINE *ſalt*. See SALT.

MARINE *ſurveyor*, is the name of a machine contrived by Mr. H. de Saumarez, for meaſuring the way of a ſhip in the ſea. This machine is in the form of the letter Y, and is made of iron or any other metal. At each end of the lines which conſtitute the angle or upper part of that letter, are two pallets, not much unlike the figure of the log; one of which falls in the ſame proportion as the other riſes. The falling or pendant pallet meeting a reſiſtance from the water, as the ſhip moves, has, by that means, a circular motion under water, which is faſter or ſlower, according as the veſſel moves. This motion is communicated to a dial within the ſhip, by means of a rope faſtened to the tail of the Y, and carried to the dial. The motion being thus communicated to the dial, which has a beſt in it, it ſtrikes exactly the number of geometrical paces, miles, or leagues, which the ſhip has run. Thus the *ſhip's* diſtance is attained; and the forces of tides and currents may alſo be diſcovered by this inſtrument; which, however, has been very little uſed. See a large account of it in the Abr. Phil. Tranſ. vol. vi. p. 444, &c.

MARINES, or *Marine Forces*, a body of troops employed in the ſea-ſervice, under the direction of the lords of the admiralty. Theſe forces, while on ſhore, are regulated by martial law, and to be provided with quarters, &c. 28 Geo. II. cap. 2. 29 Geo. II. cap. 6. 30 Geo. II. cap. 11.

MARINELLA, in *Botany*, a name by which ſome authors have called the great *ſow* or garden valerian.

MARINER, the ſame with ſeaman or ſailor.

The *mariners* of a ſhip are accountable to the maſter; the maſter to the owners; and the owners to the merchant, for all damages by negligence, or otherwiſe. If a *mariner* be hired, and he deſerts the ſervice before the voyage is ended, by the law martial, and by common law, he ſhall loſe his wages: and if a ſhip is loſt by tempeſt, &c. the *mariners* loſe their wages, as well as the owners their freight; and this is to oblige them to uſe their utmoſt endeavours to preſerve the ſhip.

Perſonating *mariners*, and receiving their wages, and forging letters of attorney, &c. or falſely taking out letters of adminiſtration for the receipt of ſeamen's wages, incurs a forfeiture of 200*l.* &c. 9 and 10 W. III. cap. 41. A law act has ordained, that no maſter of a ſhip ſhall retain any *mariner*, without a contract in writing for his wages, on pain of forfeiting 5*l.* And if a *mariner* refuſe to proceed afterward on the voyage, he ſhall forfeit his wages, and on complaint to a juſtice of peace, he may commit the offender to the houſe of correction, to be kept to hard labour. Alſo *mariners* abſenting from ſhips, incur a forfeiture of two day's pay, for every day's abſence, to the uſe of *Greenwich* HOSPITAL; and leaving the ſame before diſcharge by writing, forfeit one month's wages. But this ſhall not debar any *mariner* belonging to a merchant ſhip, from entering into the king's ſervice, &c. and on the arrival of any ſhip, the maſter is to pay his men their wages in thirty days, or at the time of their diſcharge (deducting the penalties impoſed), on pain of 20*l.* 2 Geo. II. cap. 36. Maſters of Britiſh and Iriſh ſhips, trading to the chief ports of Spain, are to pay a certain tonnage duty to perſons there, on the freight of goods and merchandize, as a contribution for relief of ſeamen ſhipwrecked, and other diſtreſſed ſubjects, &c. 9 Geo. II. cap. 25. A like duty to be paid by all maſters of veſſels, &c. going from any part of his majeſty's dominions to Leghorn, for relieving *mariners* that are ſhipwrecked, and taken in war. 10 Geo. II. cap. 14.

By 20 Geo. II. cap. 38. for the relief and ſupport of maimed and diſabled ſeamen, and the widows and children of ſuch as ſhall be killed or drowned in the merchants ſervice, reciting that there is no penſion for ſeamen diſabled, &c. in the merchants ſervice, and that they are willing to allow 6*d.* per month out of their wages, for the relief of ſuch as ſhall be diſabled, &c. and the widows and children of ſuch as ſhall be killed, &c. a corporation is erected, by the name of the preſident and governors, for the relief and ſupport of, &c. who may purchaſe lands for building an hoſpital, and are to pro-

vide

vide for disabled seamen therein, and to allow pensions to such as they shall think proper, their widows and children. Seamen who have not served five years in the merchants service, and contributed 6d. per month, are not to have the benefit of this act. Seamen in the merchants service are to pay 6d. per month, which the master of the ship is to retain out of their pay, and pay it to the corporation. *Mariners* in the East India company's service are exempted from the duty, and excluded the benefit of this act. 13 Geo. II. cap. 17. See GREENWICH HOSPITAL.

Mariners wandering up and down, and who shall not settle themselves to work, or have not a testimonial under the hand of a justice, shewing where they landed, and whither to go, &c. or having such testimonial, if they exceed the time limited more than fourteen days, not being sick in their passage home, &c. are guilty of felony by 39 Eliz. cap. 17. But if they cannot work, for want thereof, the two next justices, upon their complaint, shall take order that they may be provided of work; or otherwise may tax the whole hundred, till relief shall be had. Stat. ibid. And every parish may be charged for relieving *mariners*, as for maimed soldiers; and they shall be relieved by the treasurer of the county, &c. 43 Eliz. cap. 3.

By 1 Geo. II. stat. 2. cap. 14. no seaman aboard his majesty's ships can be arrested for any debt, unless the same be sworn to amount to at least 20*l*. The method of ordering seamen in the royal fleet, and keeping up a regular discipline there, is directed by certain express rules, articles, and orders, first enacted by the authority of parliament, soon after the Restoration: 13 Car II. stat. 1. cap. 9. but since new-modelled and altered, after the peace of Aix la Chapelle, 22 Geo. II. cap. 33. to remedy some defects, which were of fatal consequence in conducting the preceding war. In these articles of the navy, almost every possible offence is set down, and the punishment thereof annexed: in which respect the seamen have much the advantage over their brethren in the land service; whose articles of war are not enacted by parliament, but framed from time to time, at the pleasure of the crown. For these articles, see NAVY. Blackst. Com. vol. i. p. 420.

MARINERS-*compass*. See COMPASS.

MARIO, in *Ichthyology*, a name given by Pliny, and other of the old Roman authors, to a large fish allied to the accipenser or sturgeon. There seems, from all that they have said of it, great reason to believe that it was the fish we at present call HUSO, or the ichthyocolla-fish, from isinglass made of it. Artedi makes this a species of the accipenser or sturgeon, and distinguishes it by the name of the accipenser without tubercles.

MARJORAM, *origanum*, in *Botany*, a genus of the *didynamia gymnospermia* class. Its characters are these: the flower is of the lip kind, having a cylindrical compressed tube; the upper lip plain, erect, obtuse, and indented; the under lip trifid, the segments being nearly equal; these are disposed on spikes, composed of oval coloured leaves, placed over each other like the scales of a fish; the flowers have four slender stamina, two being as long as the petal, the other two longer, terminated by single summits; they have a four-cornered germen, supporting a slender style, inclining to the upper lip, crowned by a bifid stigma; the germen afterward turns to four seeds, that up in the empalement of the flower. Miller enumerates thirteen species, and Linnæus eleven.

The common sweet *marjoram*, though a plant so commonly cultivated with us, seldom or ever ripens its seeds in England; and, as it is an annual plant, we are obliged yearly to have a supply of its seeds from the south of France and Italy, where it grows wild in great abundance. The seeds are sown in the latter end of March, on a dry warm spot; and when they are come up about an inch high, they should be transplanted into beds of rich earth, at six inches distance every way, these are to be watered till they have taken root, and cleared from the weeds; and it is always found that those which have been transplanted produce finer and larger knots of heads, than those which remain where they were sown. They flower toward the latter end of July, at which time they are to be pulled up, and dried in a shady place for use. Miller.

An essential oil is obtained from the leaves and tops of sweet *marjoram*, which, when carefully drawn, is of a pale yellow colour, and of a hot penetrating taste. This plant has been chiefly recommended in disorders of the head and nerves, in uterine obstructions and mucous discharges, proceeding from a laxity and debility of the solids, and a sluggish state of the juices, and in the humoural asthmas and catarrhs of old people. The powder of the leaves, their distilled water, and the essential oil properly diluted, are agreeable errhines, and accounted particularly useful in pituitous obstructions of the nostrils, and disorders of the olfactory organs. Lewis.

The leaves and flowery tops of the common wild *marjoram*, which grows on dry chalky hills and gravelly grounds, in several parts of England, and flowers in June, have an agreeable aromatic smell, and a pungent taste, warmer than that of the garden *marjoram*, and much resembling thyme; with which they appear to agree in medicinal virtue. Infusions of them are sometimes drank, as tea, in weakness of the stomach, disorders of the breast, for promoting perspiration of the fluid secretions in general; they are sometimes used also in nervine and anti-rheumatic baths; and the powder of the dried herb as an errhine. Distilled with water, they yield a moderate quantity of a very acrid, penetrating, essential oil, smelling strongly of the *marjoram*, but less agreeable than the herb itself; this oil [illegible] a little cotton, for easing the pains of [illegible] and sometimes diluted and rubbed on the [illegible] up the nose, for attenuating and [illegible] moors. Lewis.

The dittany of Crete, which is a species of *origanum*, with all the leaves woolly, and nodding spikes of flowers, is a very warm aromatic; the leaves, which impart their virtues both to water and rectified spirit, tinging the former of a yellowish, and the latter of a greenish colour, have been chiefly recommended as emmenagogue, alexipharmic, and vulnerary. This sort was much valued among the ancients, and applauded by their poets. It was esteemed a specific for wounds of arrows, which it drew out with wonderful ease, and according to them only grew in the island of Crete, and only in a little obscure corner of it, whence it obtained its name *Dictamnus Cretica*. It still grows in that island. M. Tournefort, who was in Crete, describes the place where it grows, and says it flourishes there almost all the year.

This is a perennial plant, and though a native of stony grounds in Greece, and the island of Candy, bears the ordinary winters of our own climate. The tops are generally supplied from Italy, with the leaves tied up in bundles, which are often damaged or decayed, and at best not superior to those of our own growth. Lewis.

MARIS, in *Ichthyology*, a name given by Charleton and some others, to a fish called by the generality of both the ancient and modern writers, *smaris*, and by some *scaramouider*, from its whitish colour, and its external resemblance to the fish called *mœnis* and *mana*; it is, like that fish, a species of the sparus; and is distinguished by having a black spot on each side, and the tail and bellyfins red.

MARISCA, a word used by chirurgical writers to express an excrescence about the anus.

MARITACACA, in *Zoology*, the name of a very remarkable American animal, more usually known by the name of the OPOSSUM.

MARITIME, of *mare*, *sea*, denotes any thing belonging to the sea.

MARITIME *courts*. See COURT *of Admiralty*.

MARITIME *affairs*, is used in contradiction to the CIVIL and MILITARY estate, to express that part of his majesty's subjects, that are occupied in naval or sea service. See MARINERS and NAVY.

MARITUS, in the chemical jargon, a word used to express the sulphur of metals. The writers on the subject of the philosophers stone usually express themselves in this enigmatical manner, calling sulphur the husband, and mercury the wife in all metals; which, as they are more or less perfectly combined, make the metal more or less pure, and approaching to perfection.

MARK, in *Matters of Commerce and Manufactures*, a certain character struck, or impressed, on various kinds of commodities, either to shew the place where they were made, and the persons who made them; or to witness they have been viewed and examined by the officers or magistrates charged with the inspection of that manufacture; or, lastly, to shew that the duties imposed thereon have been regularly acquitted.

Thus are cloths, leathers, cutlery-ware, paper, plate, weights, measures, &c. to be *marked*.

The *mark* on goods also is what ascertains the property or goodness thereof, &c. And if one man shall use the mark of another, to the intent to defraud him damage, action upon the case lieth. A penalty is inflicted in this case, by the stat. 33 Eliz. cap. 8.

MARK is also a particular sign or character, known only to the trader who pitches on it; whereby, being fixed to any commodity, he recollects the price it cost him.

These *marks*, otherwise called *numerals*, are taken according to the fancy of those who use them; but, ordinarily, they are chosen from among the letters of the alphabet, each having a relation to some particular number of figures. They are of so much use in trade, that the

the reader will not take it amiss, if we infert a little table to ſerve as a model for their conſtruction:

A	B	C	D	E	F	G	H	I	K	L	M
0	1	2	3	4	5	6	7	8	9	10	20

One example will give the whole uſe of this table. Suppoſe, v. g. I would put on a piece of ſtuff, that it coſt 37*s.* 6*d.* per ell. I put an M for 20*s.* an L for 10*s.* an H for 7*s.* and a G for 6*d.* ſo that the ſeveral letters written after each other (obſerving always to ſeparate ſhillings from pounds, and from pence, by points) will make this *mark* M. LH. G. equal to 37*s.* 6*d.*

Note, the *mark* may be diverſified infinitely, by adding other figures to the letters, in lieu of theſe.

Ordinarily ſome word of a proper number of letters, all different ones, is choſen; that no relation may be traced among the letters: which may be done in the table here given.

MARK, *ſpecies*, the ſame with LAND-*mark*.

MARK, *letter of*. See LETTERS and MARQUE.

MARE, in the *Manege*. A horſe *marks*, that is, he ſhews his age by a black ſpot, called the bud or eye of a bean, which appears when he is five and a half, in the cavity of the corner teeth, and is gone when the horſe is eight years old. After that age he ceaſes to *mark*, and is ſaid to have razed. See EYE *of a bean*.

Full-MARKED is the ſame with *counter-marked*.

MARK, among *Bowlers*. See BOWLING.

St. MARK's *Goſpel*, a canonical book of the New Teſtament, being one of the four Goſpels. *St. Mark* wrote his Goſpel at Rome, where he accompanied St. Peter, in the year of Chriſt 64, or 65. Many of the moſt ancient writers aſſert, that *St. Mark* was no more than an amanuenſis or interpreter to St. Peter, who dictated this Goſpel to him; others affirm that he wrote it after St. Peter's death. It is probable that it was not compoſed long before Peter's death, and that it was not publiſhed, or did not become generally known, till after the death of Peter and Paul. This Goſpel appears, from the accounts given of it by the ancients, to contain the ſubſtance of Peter's preaching: and the Goſpel itſelf affords evidences of its being writ according to that apoſtle's diſcourſes, or according to information and directions given by him to this evangeliſt. Many circumſtances tending to Peter's honour, are not mentioned in this Goſpel: however there are many things that occur in this Goſpel, which are omitted by the other evangeliſts; and this fact proves, that *Mark* was not an epitomiſer of Matthew, as ſome have ſuppoſed, nor of any other author. The learned have been alſo divided as to the language this Goſpel was wrote in, ſome affirming it was compoſed in Greek, which is the more general and probable opinion, others in Latin. Several of the ancient heretics received only the Goſpel of *St. Mark*; others, among the Catholics, rejected the twelve laſt verſes of this Goſpel. But Dr. Lardner refers thoſe who doubt the genuineneſs of this part of the Goſpel, for ſatisfaction to Dr. Mill, and to the obſervations of Grotius, at the beginning of that chapter, and to Beza upon the ninth verſe; and for explaining thoſe twelve verſes, and reconciling them with the other evangeliſts, he refers to Grotius and other commentators. Lardner's Cred. vol. xv. p. 209.

St. MARK, *canons of*, a congregation of regular canons, founded at Mantua, by Albert Spinola, a prieſt, towards the end of the twelfth century.

Spinola made a rule for them, which was approved, corrected, and confirmed, by ſeveral ſucceeding popes. About the year 1450, they were reformed, and followed only the rule of St. Auguſtine.

This congregation, which at firſt conſiſted of eighteen or twenty houſes of men, and of ſome for women, ſituate in Lombardy, and the ſtate of Venice, having flouriſhed for the ſpace of four hundred years, declined by little and little, and was at length reduced to two convents; and, in 1584, that of *St. Mark* at Mantua, which was the chief, was given, with the conſent of pope Gregory XIII. to the CAMALDULIANS; and ſo the congregation became extinct.

St. MARK, *knights of*, an order of knighthood in the republic of Venice, under the protection of *St. Mark* the evangeliſt.

The arms of the order are, a lion winged gules, with this device, *Pax tibi, Marce evangeliſta*. This order is never conferred but on thoſe who have done ſignal ſervices to the common cauſe.

MARK, or MARC, alſo denotes a weight uſed in ſeveral ſtates of Europe, and for ſeveral commodities, eſpecially gold and ſilver in France: where it was introduced under Philip I. about the year 1080.

The *mark* is divided into eight ounces, or ſixty-four drachms, or a hundred and ninety two deniers or penny-weights, or a hundred and ſixty oſterlins, or three hundred mailles, or ſix hundred and forty ſelins, or four thouſand ſix hundred and eight grains.

In Holland, particularly at Amſterdam, the *mark* weight is alſo called Troy-weight, and is equal to that of Paris.

When gold or ſilver are ſold by the *mark*, it is divided into twenty-four carats; the carat into eight penny-weights, the penny-weight into twenty-four grains; and the grain into twenty-four primes. See CARACT.

MARK is alſo uſed among us for a money of account; and, in ſome other countries, for a coin.

The *Engliſh mark* is two-thirds of a pound ſterling, or 13*s.* 4*d.* and Matthew Paris obſerves, it was of the ſame value in 1194. The ancient Saxons, as many antiquarians have ſuppoſed, called the *mare*, MANCUS, or *mancuſa*, and *mares*; among them it was equivalent to thirty pence, i. e. to ſeven ſhillings and ſix pence of our money. But Dr. Miller, dean of Exeter, has lately ſuggeſted that the MANCUS and *mark* were not the ſame. Dr. Clarke obſerves, that the Daniſh ſilver *mark* was 20*s.* or one hundred Saxon pennies; and that the gold *mark* was twelve times as much; whereas the French *mark* was 13*s.* 4*d.* or one hundred and ſixty pence: and he has ſhewn, that the method of computing by the ſilver *mark* was introduced later into France, where it commenced between A. D. 1075, and 1093, than into England. He diſcovers traces of it in England, from the Daniſh kings till after the time of Henry II. The gold coins ſtruck from Edw. III. to Edw. IV. were diviſions of the *mark*, as half-*marks*, quarter-*marks*, and half-quarter-*marks*, at 6*s.* 8*d.* 3*s.* 4*d.* 2*s.* 2*d.* each: but from Edw. IV. when our connections with France ceaſed, the old way of computing by the pound came again into faſhion; but, as that by *marks* was jointly uſed, angels, and angelots, or half-angels, at 6*s.* 8*d.* and 3*s.* 4*d.* each, paſſed ſometimes as parts of them. However about forty years afterwards, this regard to the *marks* in our coins was quite laid aſide, and all the principal gold coins were ſtruck in proportion to the pound ſterling. Connexion of the Roman, Saxon, and Engliſh Coins, &c. p. 307, &c.

The *mark-lubs*, or *Lubeck-mark*, uſed at Hamburgh, is alſo a money of account, equal to one-third of the rix-dollar, or to the French livre. Each mark is divided into ſixteen ſols lubs.

Mark-lubs, or *daniſh*, is alſo a Daniſh coin, equal to ſixteen ſols-lubs, or twenty French ſols.

Laſtly, *mark* is a copper-coin in Sweden, equal to two pence farthing ſterling. It is divided into eight rouſtiqs, and each rouſtiq into two allerreures.

The Sweediſh ſilver *mark* is a money of account, equal to three copper *marks*; though ſome make it a real coin. See COIN.

MARKET, a public place in a city or town, where proviſions are expoſed to ſale.

The word is formed from the French *marché*, which ſignifies the ſame.

MARKET is alſo uſed for a liberty or priviledge, either by grant or preſcription, whereby a town is enabled to keep a *market*.

Bracton obſerves, that one *market* ought to be diſtant from all others at leaſt ſix miles and a half, and a third of an half. See FAIR.

In former times, it was cuſtomary to have moſt fairs and *markets* kept on Sundays, and in the church yard; ſo that matters of buſineſs and devotion were tranſacted all at the ſame place and time; which cuſtom, though prohibited by ſeveral kings, particularly 13 Ed. I. ſtat. 2. cap. 6. was yet held up till the reign of king Henry VI. when it was effectually ſuppreſſed, 27 Hen. VI. cap. 5. In many places they are ſtill kept in the church-yard.

In the country, things ſold in the *markets*, are to be in the uſual place appointed for the ſale; but in London, every ſhop is a *market* overt, for ſuch goods as are put there, to be ſold by the trade of the owner; though if the ſale be in a warehouſe, and not publicly in the ſhop, the property is not altered. Sale upon a Sunday, though in a fair or *market*, will not alter the properties of the thing ſold.

Perſons that dwell in the country, may not ſell wares by retail in a *market*-town, except in open fairs; but countrymen may ſell goods in groſs there. 1 and 2 P. and M. cap. 7. All contracts for any thing vendible in *markets*, &c. ſhall be binding, and ſales alter the property, if made according to the following rules. 1. The ſale is to be in a place that is open, ſo that any one who paſſeth by may ſee it, and be in a proper place for ſuch goods. 2. It muſt be an actual ſale, for a valuable conſideration. 3. The buyer is not to know, that the ſeller hath a wrongful poſſeſſion of the goods ſold. 4. The ſale muſt not be fraudulent, betwixt two, to bar a third perſon of his right.

5. There

5. There is to be a sale and a contract, by persons able to contract. 6. The contract must be originally and wholly in the *market* overt. 7. Toll ought to be paid, where required by statute. 8. The sale ought not to be in the night, but between sun and sun; though if the sale be made in the night, it may bind the parties. Sale of goods stolen in London, to brokers, &c. alters not the property, 1 Jac. I. cap. 21. And the statutes, which ordain, that toll-takers shall be appointed in *markets* and fairs, to enter in their books the names of horses, &c. secure the property of stolen horses to the owner, although sold in a fair or *market*, if he repays what was *bona fide* paid for the HORSE. 2 and 3 P. and M. cap. 7. 31 Eliz. cap. 12. A pie-powder COURT is incidental to a *market*, as well as a fair: keeping a fair or *market*, otherwise than it is granted, as on two days, when only one is granted, or on any other day than that appointed, &c. is cause of forfeiture. And if a person erects stalls in a *market*, and does not leave room for the people to stand and sell their wares, so that they are thereby forced to hire such stalls, taking money for the use of them is extortion.

MARKET, *court of the clerk of the*, is incident to every fair and *market* in the kingdom, to punish misdemeanors therein; and a COURT of *pie poudre* is to determine all disputes relating to private or civil property. The object of this jurisdiction, (see stat. 17 Car. II. cap. 19. 22 Car. II. cap. 8. 23 Car. II. cap. 12.) is principally the cognizance of weights and measures, to try whether they be according to the true standard thereof or no: which standard was anciently committed to the custody of the bishop, who appointed some clerk under him to inspect the abuse of them more narrowly; and hence this officer, though now usually a layman, is called the clerk of the *market*. If they be not according to the standard, then, beside the punishment of the party by fine, the weights and measures themselves ought to be burnt. This is the lowest court of criminal jurisdiction in the kingdom.

MARKET, *clerk of the*, in the king's household. See CLERK-MARKET-*towns*. See TOWNS.

MARKING-*yarn*, in ships of war, is white yarn spun the wrong way, and put into all cordage of three inches and upwards, as the king's work. Blanki. Nav. Exped. p. 103.

MARLE, MARGA, a kind of slightly coherent earth, not in the least ductile or viscid while moist, most easily diffusible in, and difunited by water, and by it reduced into a soft loose incoherent mass. *Marles* are earths composed of different proportions of argillaceous and calcareous earths: from the latter they derive the property of effervescing with acids, and they are fusible by fire, as all mixtures of these two earths are. By a less heat, if the calcareous earth predominates, they are calcinable into a kind of quick-lime; and if the clay predominates, they may be changed by fire into hard masses, capable of striking ignited sparks from steel.

The word comes from the ancient Celtic *margo*, mentioned by Pliny: it was afterwards called *margila*.

There are several sorts of *marle*, of different colours and qualities; as the ash and grey, the yellow, the brown, and the blue; but the principal are *white* and *red*. Of the white, some are not acted upon by acids, as the *terra* SAMIA and MELIA, and others are alcaline, as the TERRA *Cimolia* and CIMOLIA. The red *marles* are not acted upon by acids, and are used as manure; the ashen grey are alcaline; the yellow are not acted upon by acids, and are used as manures; the brown are the different species of FULLER'S *earth*; and the blue, not acted upon by acids, are used for manure.

The *marles* in the northern parts of England contain sand, and run into a sort of loam: those in Sussex are more like fuller's earth, and therefore are by much the fattest and richest.

Marle, in general, is much of the nature of chalk; and the potters find, that when either chalk or *marle* happens to be mixed with their clay, they will burn with the red of the substance, and the vessels will seem very sound; but as soon as any water is put in them, they will run, the chalk or *marle* having been burnt into a sort of lime, and flaking like common lime with the water.

The *marles* that are so sandy, that they can scarce hold together, are a very good manure for cold clay-lands, and are an objection to the general rule, that *marle* is not to be used to clay. *Marle*, in general, suits best with hot lands, for it is apt to bind and fadden the tough clays; but as there are no rules without their exceptions, where *marle* is not laid too thick, and is not of too binding a kind, it will often very much improve pasture-grounds, though they are upon a clayey soil.

Cow-shut or stone-*marle* is, in most countries, found under clay, or low black land, seven or eight feet deep; clay and steel-*marle* sometimes under sandy land: in clayey ground it seldom lies more than three foot deep; but in sandy ones it is often much deeper. The stone, slate, or *flag marle* is found near rivers and sides of hills, and is a very lasting manure: the peat or delving *marle* is the strongest of all, and found on the sides of hills, and in wet boggy grounds. The paper *marle*, which lies near coals, is little esteemed. The Sussex *marle* commonly shews itself pretty low among the broken strata of hanging grounds.

For the digging of *marle* they commonly use pick-axes, shovels, spades, and wheel-barrows; and where the pit is broad, that they can make an easy ascent, small carts of four feet ten inches long, and two feet three inches wide, and about fourteen inches deep, made so that a load is very easily shot out of them.

The goodness of *marles*, says Miller, may be better judged of by their purity and uncompoundedness than by their colour: thus, if the *marle* will break in pieces like dice, or into thin flakes, or is found [illegible] ore, and without mixture of gravel or sand [illegible] Like flate stones, and shatter after [illegible] when it has been exposed to the [illegible] gether when thoroughly dry, like [illegible] and tender, and will open, and [illegible] which it is laid, it will be beneficial [illegible] the goodness of *marle*, by putting some of it into [illegible] of water; and reckon it good, if it diffolves as soon as it comes to the bottom; if it sparkle in the water, and feel fat between the fingers; but the fureft fign of its goodness is, if it diffolves by wet or froft. The ftrength of *marle* may alfo be known, by putting a lump of it into a glafs of good vinegar, where a conſiderable fermentation indicates its goodneſs.

Marle is fuppoſed by ſome to be fruitful from its falt and oily quality; the falt it is fuppoſed to contract from the air, and therefore many are of opinion, that the longer it is expoſed to the air before it is uſed, the better. They lay it upon the graſs-ground, in ſome places, three or four years before they plow it up: and when they cover the arable lands with *marle*, they will not plow, in many places, to more than an inch deep, that they may not bury it. Markham, indeed is of a contrary opinion, and would have it buried deep, that the ſun may not draw out its virtue. The *marles* of different places are in themſelves ſo different, that both theſe opinions ſeem right in part; the *marle* of Suſſex being found to ſucceed beſt where buried deep, as ſoon as taken from the pit; and thoſe of the north of England feldom doing much good to the lands, unleſs they are expoſed a long time firſt.

Others, however, aſcribe the fertilizing quality of *marle* to its calcareous earth, which is known to be a powerful fertilizer of land: or it may introduce a certain degree of tenacity into too light and ſandy ſoils, by which means the water, which is the principal pabulum of plants, is prevented from eſcaping too faſt by evaporation. The experience of the farmers in different places has ſhewn alſo, that different times are to be obſerved for the laying it on, according to its nature and that of the land to be improved by it. In Suſſex they always lay on the *marle* in the beginning of winter; and in Staffordſhire in May and June. Good *marle* will flake lime with the ſun's heat in a hot day, eſpecially if there has happened any rain. Some farmers harrow in the *marle*, juſt before they plow the land, which is a very good way to mix it perfectly. Cole-ſeed, clover, and all kinds of hay-plants, grow well upon *marled* lands. Lands ſcated on *marle* are uſually very rich, though in their own nature cold and heavy. The deeper theſe lands are turned up in plowing, the better crops they will always yield. Mortimer's Huſbandry, p. 95.

It is a very material circumſtance in the *marling* of land, to find out how much the land requires of this manure; and till experience has thoroughly ſhewn this, it is better to err in laying on too little than too much, becauſe the latter is a fault not to be remedied. It is to be obſerved alſo, that *marle* never makes ſo great improvement on land the firſt year as it does afterwards.

In Staffordſhire, they lay two [illegible] of *marle* upon an acre of land of the [illegible] lands; [illegible] where the ſoil is black, looſe, and [illegible] they will lay on three or four hundred [illegible] an acre; it being a rule with them, that this [illegible] *marled* too much. If the mould be thin, [illegible] inches; if deep, it muſt have the more.

It is beſt ſowing of *marle* [illegible] in winter; becauſe if theſe lands are well [illegible] they will be very mellow and hollow, which will [illegible] the earth's ſinking from the roots of the corn, [illegible] ſo much. If *marle* ſuddens land, or makes it [illegible] muſt be well dunged, and laid down for [illegible] In Staffordſhire, after their land is *marled*, they [illegible] crops following: after the firſt crop [illegible] they plow in the wheat ſtubble in December, [illegible] if the weather proves frothy, to mellow it; they [illegible] it again in April. They then ſow it with barley, allowing three buſhels

bushels of seed to an acre. The common produce of this is thirty bushels. After they sow peas, for which they plow only once in the February following, allowing only three bushels of seed to an acre, as in the barley. Next after this, if they intend six crops, they sow wheat again upon the peas-crop; the fifth crop is barley again; and the sixth year's crop is red oats. Some sow two or three crops more, when the ground has been well *marled*, but that is much better let alone.

In digging for the *marle* they use in manuring their lands in Ireland, they meet with fossile horns, and other curious fossils. The *marle* always lies in the bottoms of low bogs. It is never met with in any other places, and is found by boring with augres made for that purpose. It usually lies at five, seven, or nine feet depth. The obtaining it in many places is attended with very considerable expences, in draining off the water. The manner of digging it is this: they employ six able labourers, and a supernumerary; and these cut up a hole of twelve feet square, which is supposed a pit that this number of men can manage in one day. Four men dig, two throw it up, and two throw it by, and the supernumerary man supplies defects on all occasions. For the first three feet they dig through a fuzzy earth, fit for making of turf or fuel. Under this lies a stratum of gravel, of about half a foot. Under this often, for three feet more, there is a more kindly moss, which would make better fuel. This lower stratum of turf is always full of fossile wood, which is usually so soft, that the spade cuts as easily through it, as through the earth it lies in. Under this, for about three inches, is found a series of leaves, principally of the oak; these appear very fair to the eye, but fall to pieces on touching; and this stratum is sometimes interrupted with vast heaps of seed, which seem to be broom or furze-seed. In some places there appear berries of different kinds; and in others, several species of sea-plants, all lying in the same confused manner as the oak-leaves. Under this vegetable stratum there lies one of blue clay, half a foot thick, and usually full of sea-shells. This blue clay is not so tough as common clay, but is thrown carefully up, and used as *marle* in some places. Under this always appear the right *marle*; the stratum of this is usually from two to four feet thick, and sometimes much more. Phil. Trans. N° 204. p. 122.

This *marle* looks like buried lime, and is full of shells; which are usually of a small size, and of the periwinkle kind; but there are several other sorts, at times, found among them. Among this *marle*, and often at the very bottom of it, are found great numbers of very large horns of the deer-kind, which are vulgarly called elks-horns. These, where they join to the head, are thick and round; and at that joining there grows out a branch, which is about a foot long, and seems to have hung just over the creature's eyes; it grows still round for about a foot above this, and then spreads broad, and terminates in branches, long and round, turning with a small bend. The labourers are obliged to work in a hurry in all these pits, so that they seldom bring them out whole. There are also, at times, found the leg-bones, and other parts of the skeletons of the same beasts; but this more rarely, only a few together, and but in few places.

MARLE, in *Medicine*, has been esteemed an astringent, and given as such in diarrhœas, dysenteries, and hæmorrhages: the red kind is preferred for the last intention, though the difference is hardly worth regarding. The Germans give it also in fevers, in convulsions, and particularly in epileptic cases; also in internal bruises.

MARLE *dice*, in *Husbandry*, a name given by the people of Staffordshire to a reddish *marle*, that breaks into small square pieces like dice, or else into thin flakes, in the manner of lead-ore, and looks smooth on the surface. This is a good manure, and the way of judging which of it is best, is to expose it to the air in rainy weather, or to put it in water. That which moulders soonest to powder in the air, and breaks quickest in the water, is sure to be the best, and proves very beneficial to land.

MARLY, *marling of*, in *Hydraulics*, is a very complex machine for raising water, at *Marly*, about ten miles north-west of Paris, the primum mobile whereof is an arm of the river Seine, which, by its stream, furnishing a fall of water, of three feet, turns fourteen large wheels, which work the bellows, and these with pistons raise the water into the pumps; and with other pistons force it up its pipes against the front of a hill to a reservoir in a stone tower. The cistern of the tower, which receives the water raised from the river, is 600 feet higher than the lower and of the first stages of the lower engines of the machine. The latter is also an aqueduct of thirty-six arches; whence the water is separated into different conduits, which lead it to *Marly*, and formerly led it to Versailles and Trianon. The number of pumps in this machine is 253; and the quantity of water raised by it, amounts to 5258 tons in twenty-four hours, or near 220 tons per hour, or 3⅔ tons per minute: but the *London-bridge* WATER-*works*, with four wheels only, raise 11724 tons in twenty-four hours, which is almost twice and a quarter as much. Some of the largest of our fire or STEAM-*engines*, used in England, will raise as much water as that of *Marly* to the same height, and not cost above 10,000l.

This *machine*, which began to work in 1682, and is said to have cost cost above four millions of pounds sterling, was made by one Rennequin, a common mechanic of Liege, and has a great many excellent contrivances; but yet does not raise all the water that it might have done, because the maker did not know how to give the river Seine all the advantages of which it was capable. Hence appears the necessity of a mechanic's being well acquainted with mathematics; or that able mathematicians should apply themselves to mechanics more than they do, and not think it below them to direct workmen. See Desagul. Exper. Philos. vol ii. p. 442 to 449.

According to Dan. Bernoulli's computation, the effect of the *machine at Marly* is not more than ⅓ of its absolute force; that is, there is a loss of ⅔ of that force. Dan. Bernoul. Hydrodyn. p. 182.

MARLINE, on board a ship, is a small line made of hemp untwilled, that it may be the more gentle and pliable: its use is to seize the ends of ropes from fairing out. They use it also to seize the straps at the arse (as they call it) or lower end of the block. See HOUSE-*line*.

MARLING, in *Sea Language*, denotes the art of winding any small line, as *marling*, spun-yarn, pack-thread, &c. about a rope, so that every turn is secured by a sort of knot, so as to remain fixed in case all the rest should be cut through by friction, &c.

Marling is commonly used to fasten slips of canvas, called parrils, or PARCELLING, upon the surface of a rope, to prevent it from being galled by another rope that rubs against it, to attach the foot of a sail to its bolt-rope, &c.

MARLING *a sail*, is when being so rip't out of the bolt-rope, that it cannot be sewed in again, the sail is fastened by a *marline*, put through the eye-let holes, made in it for that purpose, under the bolt-rope.

MARLINGS*pike*, is an iron pin, tapered to a point, and furnished with a large round head. It is principally used to penetrate the twists or strands of a rope, in order to introduce the ends of some other through the intervals, in the art of knotting or splicing. It is also used as a lever, on many other occasions, about the rigging, particularly in fixing the seizings upon the shrouds, block-strops, clues of the sails, &c. Falconer.

MARMALADE, a confection made of the juice or pulp of some fruit, as plums, apricots, quinces, boiled with sugar into a consistence.

The *marmalade* of quinces is the most frequent: it is astringent, and grateful to the stomach.

MARMARO-*sphera*, in *Natural History*, is a species of stones forming continued strata, bright and beautiful, of very lively colours, and of a constitution so fine, that they will take a good polish: in all which particulars they agree with the genus of MARBLES, but differ from them in that they are never calcareous, nor do they ferment with acids. To the same class belong the GRANITES and the PORPHYRIES.

The *marmaro-sphera* are stones of a compact, uniform texture, like that of marbles; some of them are vitrifiable, others not; and some are of such hardness, as to strike fire with steel. Of this kind is the BASALTES. Da Costa's Hist. Foss. p. 252, &c.

MARMARYGÆ, a word used by the old writers in medicine, to express sparks of fire, or the appearance of such flashing before the eyes in some disorders.

MARMOR, *marble*, in *Natural History*. See MARBLE.

MARMORARIA, in *Botany*, a name given by some authors to the *branchia ursina*.

MARMORATA *aurium*, a term used by some authors to express ear-wax.

MARMORELLA, in *Botany*, a name by which some authors have called AGRIMONY.

MARMOREUS *tartarus*, a word used by some authors to express the hardest kind of the calculus, or STONE in the human bladder.

MARMOROIDÆ, in *Natural History*, are stones, which, in their nature, texture, appearance, and other properties, resemble MARBLES; and only differ from them, in that the bodies of this genus never form continued strata, but are only found in loose independent masses, lodged in strata of other substances. Mr. Da Costa subdivides these into *marmoroida* of a plain structure, and those which contain shells, corals, and other extraneous bodies. Hist. Fossils, p. 241, &c.

MARMOT-*fish*. See FALX.

MAR-

MARMOTTE, *marmotta*, *mus marmota*, of Linnæus, in *Zoology*, the mountain-rat, a creature very common in many parts of Europe, and frequently carried about as a shew by the poor Savoyards. It is about the size of a leveret; its whole figure and appearance are like the common rat, whence it has its name; its fur is much harder or farther than that of the rabbit, and its colour a reddish tawney; the end of its tail is black; its eyes are large and prominent, and its ears short, hid in the fur, and seeming as if cut off; it has two large teeth at the front of each jaw, as the squirrel, and other creatures of this kind, and these are not white, but yellow, as in the beaver; its nose and mouth are adorned with a large number of black whiskers, making a sort of beard; the tail is about five inches long, and the legs are thick and covered with long hair; its toes, which are four before and five behind, are disposed as in the bear, and its claws are very long and strong, by means of which it digs the earth very readily; it makes great use of its hinder legs, and sometimes walks on them in an erect posture; its back always appears very fleshy and fat, though the rest of the body be ever so lean. Ray, Syn. Quad. p. 221. *Vol.* III. *Synd. fig.* 32. They will play with one another in the manner of kittens, and make a soft and not disagreeable noise on those occasions; but when they are provoked, or when they are affected, as they always are by a change of weather, they make a very shrill and disagreeable squeaking. The *marmotte* is a creature easily bred up tame, and will be perfectly good humoured and familiar, but it hates dogs. This animal, in Poland, is said to herd in large communities, and to be governed by a regular policy.

There are other species in Maryland, Canada, Germany, Russia, and Lapland. See *Sable*-MOUSE. Pennant's Zool. p. 270, &c.

MARONITES, in *Ecclesiastical History*, a sect of eastern Christians, who follow the Syrian rite, and are subject to the pope; their principal habitation being on mount Libanus.

Motheim informs us, that the doctrine of the MONOTHELITES, condemned and exploded by the council of Constantinople, found a place of refuge among the Mardaites, a people who inhabited the mounts Libanus and Antilibanus, and who, about the conclusion of the seventh century, were called *Maronites*, after *Maro*, their first bishop; a name which they still retain. None, he says, of the ancient writers, give any certain account of the first person who instructed these mountaineers in the doctrine of the Monothelites: it is probable, however, from several circumstances, that it was John Maro, whose name they had adopted; and that this ecclesiastic received the name of Maro, from his having lived in the character of a monk, in the famous convent of St. Maro, upon the borders of the Orontes, before his settlement among the Mardaites of mount Libanus. One thing is certain, from the testimony of Tyrius and other unexceptionable witnesses, as also from the most authentic records, viz. that the *Maronites* retained the opinions of the Monothelites until the twelfth century, when abandoning and renouncing the doctrine of one will in Christ, they were re-admitted, in the year 1182, to the communion of the Roman church. The most learned of the modern *Maronites* have left no method unemployed to defend their church against this accusation; they have laboured to prove, by a variety of testimonies, that their ancestors always persevered in the Catholic faith, in their attachment to the Roman pontiff, without ever adopting the doctrine of the Monophysites, or Monothelites. But all their efforts are insufficient to prove the truth of these assertions to such as have any acquaintance with the history of the church, and the records of ancient times; for to all such, the testimonies they allege will appear absolutely fictitious and destitute of authority. Eccl. Hist. vol. ii. p. 37, &c. 8vo. edit.

Faustus Nairon, a *Maronite*, settled at Rome, has published an apology for *Maron*, and the rest of his nation. His tenet is, that they really took their name from the *Maron*, who lived about the year 400, and of whom mention is made in Chrysostom, Theodoret, and the Menologium of the Greeks. He adds, that the disciples of this *Maron* spread themselves throughout all Syria; that they built several monasteries, and, among others, one that bore the name of their leader; that all the Syrians, who were not tainted with heresy, took refuge among them; and that, for this reason, the heretics of those times called them *Maronites*.

Motheim observes, that the subjection of the *Maronites* to the spiritual jurisdiction of the Roman pontiff, was agreed to with this express condition, that neither the popes nor their emissaries should pretend to change or abolish any thing that related to the ancient rites, moral precepts, or religious opinions of this people: so that, in reality, there is nothing to be found among the *Maronites* that savours of popery, if we except their attachment to the Roman pontiff, who is obliged to pay very dear for their friendship. For, as the *Maronites* live in the utmost distress of poverty, under the tyrannical yoke of the Mahometans, the bishop of Rome is under the necessity of furnishing them with such subsidies as may appease their oppressors, procure a subsistence for their bishop and clergy, provide all things requisite for the support of their churches, and the uninterrupted exercise of public worship, and contribute in general to lessen their misery. It is certain that there are *Maronites* in Syria, who still behold the church of Rome with the greatest aversion and abhorrence; nay, what is still more remarkable, great numbers of that nation residing in Italy, even under the eye of the pontiff, opposed his authority during the last century, and threw the court of Rome into great perplexity. O[illegible] these non-conforming *Maronites* retired [illegible] of Piedmont, where they joined the [illegible], above six hundred in number, with [illegible] ecclesiastics at their head, fled [illegible] protection of the republic of [illegible] the violence of the inquisitors. Eccl. Hist. vol. iii. p. 208.

The *Maronites* have a patriarch, who resides in the monastery of Cannubin, on mount Libanus, and assumes the title of patriarch of Antioch, and the name of Peter, as if he deemed desirous of being considered as the successor of that apostle. He is elected by the clergy and the people, according to the ancient custom; but, since their reunion with the church of Rome, he is obliged to have a bull of confirmation from the pope. He keeps a perpetual celibacy, as well as the rest of the bishops his suffragans: as to the rest of the ecclesiastics, they are allowed to marry before ordination; and yet the monastic life is in great esteem among them. Their monks are of the order of St. Antony, and live in the most obscure places in the mountains, far from the commerce of the world.

As to their faith, they agree in the main with the rest of the Eastern church. Their priests do not say mass singly; but all say it together, standing round the altar. They communicate in unleavened bread; and the laity have hitherto partaken in both kinds, though the practice of communicating in one has of late been getting footing, having been introduced by little and little. In Lent they eat nothing, unless it be two or three hours before sunrising: their other fastings are very numerous.

To MAROON, in *Sea Language*, is to put one or more sailors ashore upon a desolate island, under pretence of their having committed some great crime. This detestable expedient has been repeatedly practised by some inhuman commanders of merchant-ships, particularly in the West Indies.

MAROTIC *style*, in the *French Poetry*, denotes a peculiarly gay, pleasant, yet simple and natural manner of writing, introduced by Clement *Marot*, and since imitated by other authors, but with most success by De la Fontaine and Rousseau.

The difference between the *Marotic* and the burlesque style is thus assigned: the *Marotic* makes a choice; the burlesque admits of all. The first is the most simple; but its simplicity has its noblenes; and, where its own age will not furnish natural expressions, it borrows them from former times: the latter is low and grovelling, and borrows false and fulsome ornaments from the crowd, which people of taste despise. The one resigns itself to nature; but examines first of all, whether the objects she presents be fit for its paintings, and takes nothing but what carries with it somewhat of delicacy and mirth: the other runs headlong into buffoonery, and affects every thing that is extravagant and grotesque. See BURLESQUE.

MAROTTI, in *Botany*, is a tall tree growing in Malabar, with leaves like those of bay, bearing a round oblong fruit, including a very large, hard, and yellowish stone, containing ten or eleven [illegible] extracted from the seeds or kernels of the [illegible] and cures the scabies and itching [illegible] the parts: it is good also, for eyes [illegible] humours; and mixed with allies, it is [illegible] impostumes and abscesses in cows [illegible] and beasts of burden. Raii Hist. P[illegible]

MARQUE, *law of*. S[illegible]

MARQUE, *letters of*, are [illegible] granted by [illegible] or state, whereby the [illegible] are legalized to make reprisals on tho[illegible] by reason application has been made for [illegible] against whom to the aggressor belongs, [illegible] subject.

The first *letter of marque* [illegible] any account in the history of this country, was [illegible] Edw. I. in 1295, against the subjects of [illegible]

These letters are granted by the law of nations, when-

ever

ever the subject of one state are oppressed and injured by those of another; and justice is denied by that state to which the oppressor belongs: and with us it is declared by stat. 4 Hen. V. cap. 7. that if any subjects of the realm are oppressed in time of truce by any foreigners, the king will grant *marque* in due form to all that feel themselves aggrieved. Which form is thus directed to be observed: the sufferer must first apply to the lord privy seal, and he shall make out letters of request under the privy-seal: and if, after such request of satisfaction made, the party required do not within convenient time make due satisfaction or restitution to the party grieved, the lord chancellor shall make him out letters of *marque*, under the great seal: and by virtue of these he may attack and seize the property of the aggressor nation, without hazard of being condemned as a robber or pirate. Blackst. Comm. vol. i. p. 259.

They are so called from the German *marche, limit, frontier*; being *jus concessum in alterius principis marcas seu limites impetendi, sibique jus faciendi*; as being a right of passing the limits or frontiers of another prince, and doing one's self justice. See LETTERS and REPRISALS.

MARQUETRY, *inlaid work*; a curious kind of work, composed of pieces of hard fine wood of different colours, fastened, in thin slices, on a ground, and sometimes enriched with other matters, as tortoise-shell, ivory, tin, and brass.

There is another kind of *marquetry* made, instead of wood, of glasses of various colours; and a third, where nothing but precious stones, and the richest marbles, are used: but these are more properly called MOSAIC *work*.

The art of inlaying is very ancient, and is supposed to have passed from the East to the West, as one of the spoils brought by the Romans from Asia. Indeed, it was then but a simple thing; nor did it arrive at any tolerable perfection till the fifteenth century, among the Italians. It seems finally to have arrived at its height, in the seventeenth century, among the French.

Till Jofin of Verona, a contemporary with Raphael, the finest works of this kind were only black and white, which are what we now call *marqueterie*; but that religious, who had a genius for painting, stained his woods with dyes, or boiled oils, which penetrated them. But he went no farther than the representing buildings and perspectives, which require no great variety of colours. Those who succeeded him, not only improved on the invention of dying the woods, by a secret which they found of burning them without consuming, which served exceedingly well for the shadows; but they had also the advantage of a number of fine new woods of naturally bright colours, by the discovery of America. With these assistances, the art is now capable of imitating any thing; whence some call it, the *art of painting in wood*.

The ground, whereon the pieces are to be arranged and glued, is ordinarily of oak or fir, well dried; and, to prevent warping, it is composed of several pieces glued together. The wood to be used, being reduced into leaves of the thickness of a line, is either stained with some colour, or made black for shadow; which some effect by putting it in sand extremely heated over the fire; others by steeping it in lime-water and sublimate; and others, in oil of sulphur. Thus coloured, the contours of the pieces are formed, according to the parts of the design they are to represent.

The last is the most difficult part of *marquetry*, and that wherein most patience and attention are required. The two chief instruments used herein are the saw and the vice; the one to hold the matters to be formed; the other to take off from the extremes, according to occasion. The vice is of wood, having one of its chaps fixed, the other moveable, and is opened and shut by the foot, by means of a cord fastened to a treadle. Its structure is very ingenious, yet simple enough, and will be easily conceived from the figure, *Joh. II. Miscellany, fig. 20*.

The leaves to be formed (for there are frequently three or four of the same kind formed together) are put within the chaps of the vice, after being glued on the outermost part of the design, whose profile they are to follow; then the workman, pressing the treadle, and thus holding fast the piece, with his saw runs over all the outlines of the design. By thus joining and forming three or four pieces together, they not only gain time, but the matter is likewise the better enabled to sustain the effort of the saw; which, how delicate soever it may be, and how lightly soever the workman may conduct it, without such a precaution, would be apt to raise splinters, to the ruin of the beauty of the work.

When the work is to consist of one single kind of wood, or of tortoise-shell, on a copper or tin ground, or *vice versa*, they only form two leaves on one another, i. e. a leaf of metal and a leaf of wood or shell: this they call sawing in counter-parts; for, by filling the vacuities of one of the leaves by the pieces coming out of the other, the metal may serve as a ground to the wood, and the wood to the metal.

All the pieces, thus formed with the saw, are marked, to know them again; and the shadow being given in the manner already mentioned, they veneer or fasten each in its place on the common ground; using for that purpose the best English glue. The whole is then put in a press to dry, planed over, and polished with the skin of the sea-dog, wax, and shave-grass, as in simple *veneering*; with this difference, however, that in *marquetry*, the fine branches, and several of the most delicate parts of the figures, are touched up, and finished with a graver.

They are the cabinet-makers, joiners, and toymen, among us, who work in *marquetry*; and the enamellers and stone-cutters, who deal in mosaic work; the instruments used in the former are mostly the same with those used by the ebonists. See EBONY.

MARQUIS, or MARQUESS, MARCHIO, a title given to a person in possession of a considerable demesne erected into a *marquisate* by letters patent; holding a middle place between the dignity of a duke and that of an earl or count.

The word, according to some authors, comes from the *Marcomanni*, an ancient people, who inhabited the marches of Brandenburg. Others derive it from the German *marche, limit*; and others from *marrisa*, which, in the Celtic language, signified *a wing of cavalry*. Nicod derives it from the corrupt Greek μαρχια, *provinces*. Alciat and Pauchet bring it from *marc, horse*, taking a *marquis* to be properly an officer of horse. Menage derives it from *marca, frontier*; and Selden, Krantzius, and Hottoman do the same. Lastly, Pasquier fetches *marquis* from the old French *marche, limit*; or from *marchir, to confine*; the guard of the frontiers being committed to them. *Marquises* were anciently governors of frontier cities or provinces, called *marches*. In Germany, they are called *margraves*.

Marquis is originally a French title: the Romans were unacquainted with it. In the Notitia Imperii, they were called *comitates limitanei*. The first time we hear of *marquises, marchiones*, is under Charlemagne, who created governors in Gascony under this denomination.

Alciat has started a question, whether a *marquis* or count should have the precedence? To decide it he goes back to the ancient function of counts; and observes, that counts, who are governors of provinces, are above *marquises*, who are only governors of frontiers; and that *marquises*, who are governors of frontier-cities, are above those counts, who are governors of small towns. He adds, that, in consequence of this distinction, the book of fiefs sometimes places *marquises* above counts, and sometimes counts above *marquises*.

Froissart observes, that the *marquisate* of Juliers was erected into a county: but now-a-days, neither *marquises* nor counts are any longer governors; and, as they are mere titles of honour, the counts make no scruple of resigning the precedency.

King Richard the Second was the first who introduced the dignity of *marquis* among us, by creating Robert de Vere earl of Oxford, *marquis* of Dublin: but this was a title without office; the frontiers being governed by *lords* MARCHERS. Selden's Titles of Honour, p. 216.

MARQUIS'S *coronet*. See CROWN.

MARRIAGE, a civil and religious contract, whereby a man is joined and united to a woman, for the ends of procreation.

The essence of *marriage* consists in the mutual consent of the parties. *Marriage* is part of the law of nations, and is in use among all people. The Romanists account it a sacrament.

The woman, with all her moveable goods, immediately upon *marriage*, passes wholly *in potestatem viri*, into the power and disposal of the husband.

The first inhabitants of Greece lived together without *marriage*. Cecrops, king of Athens, is said to have been the first author of this honourable institution among that people. After the commonwealths of Greece were settled, *marriage* was very much encouraged by their laws, and the abstaining from it was discountenanced, and in many places punished. The Lacedæmonians were very remarkable for their severity towards those who deferred *marriage* beyond a limited time, as well as to those who wholly abstained from it. The Athenians had an express law, that all commanders, orators, and persons entrusted with any public affair, should be married men. POLYGAMY was not commonly tolerated in Greece. The time of *marriage* was not the same in all places; the Spartans were not permitted to marry till they arrived at their full strength; the reason assigned for this custom by Lycurgus was, that the Spartan children might be strong and vigorous; and the Athenian laws are said to

have once ordered, that men should not marry till thirty-five years of age. The season of the year which they preferred for this purpose was the winter, and particularly the month of January, called GAMELION. The Greeks thought it scandalous to contract *marriage* within certain degrees of consanguinity; whilst most of the barbarous nations allowed incestuous mixtures.

Most of the Grecian states, especially such as made any figure, required their citizens should match with none but citizens, and the children were not allowed to marry without the consent of their parents. The usual ceremonies in promising fidelity was kissing each other, or giving their right hands, which was a general form of ratifying all agreements. Before the *marriage* could be solemnized, the gods were to be consulted, and their assistance implored by prayers and sacrifices, which were offered to some of the deities that superintended these affairs, by the parents, or nearest relations of the persons to be *married*. When the victim was opened, the gall was taken out and thrown behind the altar, as being the seat of anger and malice, and therefore the aversion of all the deities who had the care of love, as well as those who became their votaries. For the particularities relating to the bride and bridegroom, see BRIDE and BRIDEGROOM.

The ceremonies of the Spartan *marriages* being different from all others, deserve to be mentioned at length, as related by Plutarch. "When the Spartans had a mind "to *marry*, their courtship was a sort of rape upon the "persons they had a fancy for; and those they chose "not tender and half-children, but in the flower of their "age, and full ripe for a husband. Matters being agreed "between them, the *nuptiæ*, or woman that contrived "and managed the plot, shaved off the bride's hair close "to her skin, dressed her up in man's cloaths, and left "her upon a mattress: this done, the bridegroom entered in his common cloaths, sober and composed, as "having supped at his ordinary in the common hall, and "stole as privately as he could into the room where the "bride lay, untied her virgin girdle, whence ΛΥΣΙΖΩΝΟΣ, is "*to deflower*, and took her into his embraces. Having "stayed a short time with her, he returned to his comrades, with whom he continued to spend his life, remaining with them as well by night as by day, unless "when he stole a short visit to his bride; and that could "not be done without a great deal of circumspection, "and fear of being discovered. Nor was the wanting "(as may be supposed) on her part, to use her wit in "watching the most favourable opportunities for their "meeting, and making appointments when company "was out of the way. In this manner they lived a long "time, insomuch that they frequently had children by "their wives before they saw their faces by day-light. "The interview being thus difficult and rare, served not "only for a continual exercise of their temperance, and "farthered very much the ends and intentions of *marriage*, but was a means to keep their passion still alive, "which flags and decays, and dies at last by too easy "access, and long continuance with the beloved object." Potter, Archæol. book iv. c. xi. p. 205, seq.

The Romans, as well as the Greeks, disallowed of POLYGAMY. A Roman might not marry any woman who was not a Roman. Among the Romans, the kalends, nones, and ides of every month, were deemed unlucky for the celebration of *marriage*, as was also the feast of the PARENTALIA, and the whole month of May. The most happy season in every respect was that which followed the ides of June.

The Roman laws speak of second *marriages* in very hard and odious terms: *Matre jam fœcundis nuptiis functâ*, L. iii. C. de sec. nuptiis. By these laws it was enacted, that the effects of the husband or wife deceased should pass over to the children, if the survivor should marry a second time. By the law *Hoc edictali*, Cod. de sec. nupt. the survivor, upon *marrying* a second time, could not give the person he married a portion more than equal to that of each of the children. In the primitive church, the respect to chastity was carried so high, that a second *marriage* was accounted no other than a lawful whoredom, or a species of bigamy; and there are some ancient canons, which forbid the ecclesiastics from being present at second *marriages*.

Marriage, by the Mosaic law, was subject to several restrictions: thus by Levit. chap. xviii. ver. 16. a man was forbid to marry his brother's widow, unless he died without issue; in which case, it became enjoined as a duty. So it was forbid to marry his wife's sister, while she was living, ver. 18. which was not forbidden before the law, as appears from the instance of Jacob.

The ancient Roman law is silent on this head; and Papinian is the first who mentions it, on occasion of the marriage of Caracalla. The lawyers who came after him stretched the bonds of AFFINITY so far, that they placed ADOPTION on the same foot with nature.

Affinity, according to the modern canonists, renders marriage unlawful to the fourth generation, inclusive; but this is to be understood of direct affinity, and not of that which is secondary or collateral. *Affinis mei affinis, non est affinis meus.* It is farther to be observed that this impediment of *marriage* does not only follow an affinity contracted by lawful matrimony, but also that contracted by a criminal commerce; with this difference, that this last does not extend beyond the second generation; whereas the other, as has been observed, reaches to the fourth.

In Germany, they have a kind of *marriage* called *morganatic*, wherein a man of quality contracting with a woman of inferior rank, he gives her the left [illegible] lieu of the right; and stipulates in the contract that the wife shall continue in her former rank only, and that the children born of them shall [illegible] that they become bastards as to matters of [illegible] though they are legitimate in effect. They cannot bear the name or arms of the family.

None but princes, and great lords of Germany, are allowed this kind of *marriage*. The universities of Leipsic and Jena have declared against the validity of such contracts; maintaining, that they cannot prejudice the children, especially when the emperor's consent intervenes in the *marriage*.

The Turks have three kinds of *marriages*, and three sorts of wives; *legitimate*, *wives in lobin*, and *slaves*. They marry the first, hire the second, and buy the third.

The people in Java marry and have children at nine or ten years old, and the women leave child-bearing before they are thirty; and at Tonquin there are women common to any that will hire them, at eight or nine years of age.

Among all the savage nations, whether in Asia, Africa, or America, the wife is commonly bought by the husband from her father, or those other relations who have an authority over her; and the conclusion of a bargain for this purpose, together with the payment of the price, has, therefore, become the usual form or solemnity in the celebration of their *marriages*. The Hebrews also purchased their wives, by paying down a competent dowry for them; and Aristotle makes it one argument to prove that the ancient Grecians were an uncivilized people, because they used to buy their wives; and in proportion as they laid aside their barbarous manners, they left off this practice.

The English law considers *marriage* in no other light than as a civil contract; the holiness of the matrimonial state being left entirely to the ecclesiastical law, to which it pertains to punish or annul incestuous or other unscriptural *marriages*. The law allows *marriage* to be good and valid, where the parties at the time of making it were willing and able to contract, and actually did contract, in the proper forms and solemnities required by law. The disabilities for contracting are of two sorts; first, such as are canonical, and, therefore, sufficient by the ecclesiastical laws to avoid the *marriage* in the spiritual court; such as pre-contract, CONSANGUINITY, or relation by blood; and AFFINITY, or relation by *marriage*, and some particular corporal infirmities. But these disabilities in our law do not make the *marriage ipso facto* void, but voidable only by sentence of separation; and *marriages* are effected valid to all civil purposes, unless such separation is actually made during the life of the parties. Thus, when a man had married his first wife's sister, and after her death the bishop's court was proceeding to annul the *marriage*, and bastardize the issue, the court of king's bench granted a prohibition *quoad hoc*; but permitted them to proceed to punish the husband for incest.

By 32 Hen. VIII. c. 38. it is declared, that all persons may lawfully marry, but such as are prohibited by God's law, &c. And that nothing [illegible] shall impeach any *marriage* but within the [illegible] degrees: these are enumerated in the [illegible] Leviticus, and are illustrated by [illegible] manner: a man may not marry his mother, [illegible] mother's sister, daughter, [illegible] daughter, father's wife, uncle's wife, [illegible] brother's wife, wife's sister, [illegible] daughter and daughter of his wife's [illegible] a woman may not marry her father, [illegible] mother's brother, brother, son, [illegible] mother's husband, aunt's husband, [illegible] husband's brother, and son of [illegible] daughter. By the civil law first cousins [illegible]; but by the canon law both first and second [illegible] prohibited. Therefore, when [illegible] that first cousins may marry, but second [illegible] this prohibably

bably arose by confounding these two laws; for first cousins may marry by the civil law, and second cousins cannot by the canon law. But by the forefaid ſtat. 32 Hen. VIII. c. 38. it is clear, that both firſt and ſecond cousins may marry. By the ſame ſtatute all impediments, ariſing from pre-contracts to other perſons, were abolished, and declared of none effect, unleſs they had been conſummated with bodily knowledge; in which caſe the canon law holds ſuch contract to be a *marriage de facto*. But this branch of the ſtatute was repealed by 2 & 3 Ed. VI. c. 23. How far the act of 26 Geo. II. c. 33. (which prohibits all ſuits in eccleſiaſtical courts to compel a *marriage*, in conſequence of any contract) may collaterally extend to revive this clauſe of Henry the Eighth's ſtatute, and abolish the impediment of pre-contract, judge Blackſtone leaves to be conſidered by the canoniſts. We ſhall here obſerve, that on a promiſe of *marriage*, if it be mutual on both ſides, damages may be recovered, in caſe either party refuſes to marry; and though no time for the *marriage* is agreed on, if the plaintiff avers that he offered to marry the defendant, who refuſed it, an action is maintainable for the damages; but no action ſhall be brought upon any agreement, except it is in writing, and ſigned by the party to be charged. The canonical hours for celebrating *marriage* are from eight to twelve in the forenoon.

The other ſort of diſabilities are thoſe which are created, or at leaſt enforced, by the municipal laws. Theſe civil diſabilities make the contract void *ab initio*, by rendering the parties incapable of forming any contract at all. The firſt legal diſability is a prior *marriage*, or having another huſband or wife living; in which caſe, beſides the penalties conſequent upon it as a felony, the ſecond *marriage* is to all intents and purpoſes void. See BIGAMY, and POLYGAMY.

The next legal diſability is want of age: therefore, if a boy under fourteen, or a girl under twelve years of age, marries, when either of them comes to the age of conſent, they may diſagree, and declare the *marriage* void, without any divorce or ſentence in the ſpiritual court. However in our law it is ſo far a *marriage*, that, if at the age of conſent, they agree to continue together, they need not be married again. Another incapacity ariſes from want of conſent of parents or guardians. By ſeveral ſtatutes, viz. 6 & 7 W. III. c. 6. 7. 8 W. III. c. 35. 10 Ann. c. 19. penalties of 100*l.* are laid on every clergyman who marries a couple, either without publication of banns, which may give notice to parents or guardians, or without a licence, to obtain which the conſent of parents or guardians muſt be ſworn to. And by 4 & 5 Ph. & M. c. 8. whoſoever marries any woman-child under the age of ſixteen years, without conſent of parents or guardians, ſhall be ſubject to fine, or five years impriſonment; and her eſtate, during the huſband's life, ſhall be enjoyed by the next heir. Thus alſo in France, the ſons cannot marry without conſent of parents, till thirty years of age, nor the daughters till twenty-five; and in Holland, the ſons are at their own diſpoſal at twenty-five, and the daughters at twenty. And by the *marriage* act, viz. 26 Geo. II. c. 33. it is enacted, that all *marriages* celebrated by licence (for banns ſuppoſe notice) where either of the parties is under twenty-one, not being a widow or widower, without the conſent of the father, or, if he be not living, of the mother or guardians, ſhall be abſolutely void. However, proviſion is made, where the mother or guardian is non compos, beyond ſea, or unreaſonably froward, to diſpenſe with ſuch conſent, at the diſcretion of the lord chancellor; but no proviſion is made, in caſe the father ſhould labour under any mental, or other incapacity. A fourth incapacity is want of reaſon. It is provided by 15 Geo. II. c. 30. that the *marriage* of lunatics, and perſons under phrenſies (if ſound lunatics under a commiſſion, or committed to the care of truſtees by any act of parliament) before they are declared of ſound mind by the lord chancellor, or the majority of ſuch truſtees, ſhall be totally void. Laſtly, the parties muſt not only be willing and able to contract, but muſt actually contract themſelves in due form of law, to make it a good civil *marriage*. Any contract made, *per verba de præſenti*, or in words of the preſent time, and in caſe of cohabitation *per verba de futuro* alſo, between perſons able to contract, was before the late act deemed a valid *marriage* to many purpoſes, and the parties might be compelled in the ſpiritual courts to celebrate it *in facie eccleſiæ*. But theſe ſpiritual contracts are now of no force, to compel a future *marriage*. Nor is any *marriage* at preſent valid, that is not celebrated in ſome pariſh-church, or public chapel, unleſs by diſpenſation from the archbiſhop of Canterbury. It muſt alſo be preceded by publication of BANNS, or by LICENCE from the ſpiritual judge. A *marriage* in purſuance of banns muſt be ſolemnized in one of the churches or chapels, where the banns were publiſhed. No parſon, vicar, &c. ſhall be obliged to publiſh banns of matrimony, unleſs the perſons to be married ſhall ſeven days before the time required for the firſt publication, deliver to him a notice in writing of their true names, and of the houſe or houſes of their reſpective abode, within ſuch parith, &c. and of the time that they have dwelt in ſuch houſe or houſes. And the ſaid banns ſhall be publiſhed upon three Sundays preceding the ſolemnization of *marriage*, during the time of public ſervice: in caſe the parents or guardians, or either of the parties who ſhall be under the age of twenty-one years, ſhall openly and publicly declare, or cauſe to be declared in the church or chapel, where the banns ſhall be ſo publiſhed, at the time of ſuch publication, their diſſent to ſuch *marriage*, ſuch publication of banns ſhall be void. And when the parties dwell in divers parithes, the curate of the one pariſh ſhall not ſolemnize matrimony betwixt them, without a certificate of the banns being thrice aſked, from the curate or the other parith. A *marriage* in purſuance of a licence (except a ſpecial licence) muſt be ſolemnized in ſuch church or chapel where the licence is granted; and no licence of *marriage* ſhall be granted by any archbiſhop, biſhop, &c. to ſolemnize any *marriage* in any other church, &c. than in the pariſh-church, &c. within which the uſual place of abode of one of the parties ſhall have been for four weeks immediately before the granting ſuch licence. By the ſame ſtatute all *marriages* ſhall be ſolemnized in the preſence of two credible witneſſes at the leaſt, beſides the miniſter, who ſhall ſign their atteſtation thereof; and immediately after the celebration of every *marriage*, an entry thereof ſhall be made in the pariſh-regiſter, expreſſing that the ſaid *marriage* was celebrated by banns or licence; and if both or either of the parties be under age, with conſent of the parents or guardians, as the caſe ſhall be, ſigned by the miniſter, and alſo by the parties married, and atteſted by the two witneſſes preſent. It is held to be alſo eſſential to a *marriage*, that it be performed by a perſon in orders; though the intervention of a prieſt to ſolemnize this contract is merely *juris poſitivi*, and not *juris naturalis aut divini*; it being ſaid that pope Innocent III. was the firſt who ordained the celebration of *marriage* in the church, before which it was totally a civil contract. And in the times of the grand rebellion, all *marriages* were performed by the juſtices of the peace; and theſe *marriages* were declared valid, without any freſh ſolemnization, by 12 Car. II. c. 33. But as the law now ſtands, we may upon the whole collect, that no *marriage* by the temporal law is *ipſo facto* void, that is celebrated by a perſon in orders; in a pariſh-church, a public chapel, or elſewhere, by ſpecial diſpenſation; in purſuance of banns or a licence; between ſingle perſons; conſenting; of ſound mind; and of the age of twenty-one years; or of the age of fourteen in males, and twelve in females, with conſent of parents or guardians, or without it, in caſe of widowhood. And no *marriage* is voidable, by the eccleſiaſtical law, after the death of either of the parties; nor during their lives, unleſs for the canonical impediments of precontract, if that indeed ſtill exiſts; of conſanguinity; and of affinity, or corporal impotency, ſubſiſting previous to the *marriage*. Blackſt. Com. vol. i. p. 433. &c.

By 26 Geo. II. c. 33. the ſubſtance of which has been already recited, if any perſon ſhall ſolemnize matrimony in any other place than a church, &c. where banns have been uſually publiſhed, unleſs by ſpecial licence, or without publication of banns, unleſs licence of *marriage* be firſt obtained, from ſome perſon having authority to grant the ſame, every ſuch perſon knowingly ſo offending, ſhall be guilty of felony, and tranſported for fourteen years; the proſecution to be within three years. By the ſame ſtatute, to make a falſe entry into a *marriage* regiſter; to alter it when made; to forge or counterfeit ſuch entry, or a *marriage* licence, or aid and abet ſuch forgery; to utter the ſame as true, knowing it to be counterfeit; or to deſtroy or procure the deſtruction of any regiſter, in order to vacate any *marriage*, or ſubject any perſon to the penalties of this act; all theſe offences, knowingly and wilfully committed, ſubject the party to the guilt of felony, without benefit of clergy. But this act doth not extend to the *marriages* of the royal family; nor to Scotland; nor to any *marriages* among the people called quakers, or among perſons profeſſing the Jewiſh religion, where both the parties are quakers or Jews reſpectively; nor to any *marriages* beyond the ſeas.

For the proportions which *marriages* bear to births, and births to burials, in ſeveral parts of Europe, Mr. Derham gives us the following table:

Names

Names of Places.	*Marriages* to Births, as	Births to Burials, as
England in general	1 to 4.63	1.12 to 1
London	1 to 4	1 to 1.1
Hantſhire, from 1569 to 1638	1 to 4	1.2 to 1
Tiverton in Devonſhire, from 1656 to 1664	1 to 3.7	1.26 to 1
Cranbrook in Kent, from 1560 to 1649	1 to 3.9	1.6 to 1
Aynho in Northamptonſhire, for 118 years	1 to 6	1.6 to 1
Upminſter in Eſſex, for 100 years	1 to 4.6	1.8 to 1
Frankfort on the Maine, in 1695	1 to 3.7	1.2 to 1
Old, Middle, and Lower Marck, in 1698	1 to 3.7	1.9 to 1
Dominions of the Elector of Brandenburg, in 1698	1 to 3.7	1.5 to 1
Breſlaw in Sileſia, from 1687 to 91		1.6 to 1
Paris, in 1670, 1671, 1672	1 to 4.7	1.6 to 1

The Editor has formed the following table, ſimilar to the preceding, from the obſervations collected and referred to by Dr. Price.

Names of Places.	*Marriages* to Births, as	Births to Burials, as
London, annual medium from 1710 to 1730	— — —	18000 to 26520, or 1 to 1.4, &c.
——— from 1759 to 1768	— — —	15710 to 21956, or 1 to 1.4, &c.
Northampton, ditto, from 1741 to 1770	— — —	155 to 191, or 1 to 1.23, &c.
Norwich, ditto, from 1740 to 1769	— — —	1057 to 1266, or 1 to 1.1, &c.
Shrewſbury, ditto, from 1762 to 1768	— — —	301 to 329, or 1 to 1.09, &c.
Mancheſter and Salford, excluſive of diſſenters, ditto, from 1755 to 1759	— — —	756 to 743.
Ditto, ditto, including diſſenters, from 1768 to 1772	— — —	1098 to 958, or 1.14, &c. to 1.
Gainſborough in Lincolnſhire, ditto, from 1752 to 1771	1 to 3.7	126 to 105, or 1.2 to 1.
Madeira, ditto, from 1759 to 1766	1 to 4.68	2201 to 1293, or 1.7 to 1.
Boſton in New England, from 1731 to 1752	— — —	538 to 668, or 1 to 1.13, &c.
Chriſtiana in Norway, in 1761	— — —	11.024 to 6929, or 1.5 to 1.
Paris, mean of ſome of the laſt years	1 to 4.3	10100 to 10400, or 1 to 1.01, &c.
Vienna, annual medium from 1757 to 1769	— — —	5800 to 6600, or 1 to 1.1, &c.
Amſterdam, ditto, for ſome of the laſt years	1 to 1.9, &c.	4600 to 8000, or 1 to 1.7, &c.
Copenhagen, ditto	1 to 3.04, &c.	2700 to 3306, or 1 to 1.2, &c.
Berlin, ditto, for five years, ending at 1759	1 to 3.9, &c.	3855 to 5054, or 1 to 1.3, &c.
Breſlaw, ditto, from 1633 to 1734	— — —	1089 to 1256, or 1 to 1.15, &c.
———, ditto, from 1717 to 1725	— — —	1252 to 1507, or 1 to 1.2, &c.
Rome, ditto, from 1759 to 1761	— — —	5167 to 7153, or 1 to 1.3, &c.
Vaud in Switzerland, ditto, for 10 years before 1766	1 to 3.9	3155 to 2564, or 1.2, &c. to 1.

For an account of the numbers of male and female ſtill-born children and chryſoms, and of boys and girls under ten, of married men and married women, and of widows and widowers, who died for a courſe of years at Vienna, Breſlaw, Dreſden, Leipſic, Ratiſbon, and ſome other towns in Germany, ſee Phil. Tranſ. Abr. vol. vii. part iv. p. 46, &c.

The reader may find many curious calculations and remarks relating to this ſubject in Dr. Price's excellent work, entitled Obſervations on Reverſionary Payments.

From the preceding table it appears, that *marriages*, one with another, do each produce about four births, both in England, and other parts of Europe. Dr. Price obſerves, that the births at Paris, as may be ſeen in the table, are above four times the weddings; and therefore it may ſeem, that in the moſt healthy country ſituations, every wedding produces above four children; and though this be the caſe in Paris, for reaſons which he has given, he has obſerved nothing like it in any other great town. He adds, that from comparing the births and weddings, in countries and towns where regiſters of them have been kept, it appears, that in the former, *marriages*, one with another, ſeldom produce leſs than four children each; generally between four and five, and ſometimes above five: but in towns ſeldom above four, generally between three and four, and ſometimes under three. It is neceſſary to be obſerved here, that though the proportion of annual births to weddings has been conſidered as giving the true number of children derived from each *marriage*, taking all *marriages* one with another; yet this is only true, when, for many years, the births and burials have kept nearly equal. Where there is an exceſs of the births occaſioning an increaſe, the proportion of annual births to weddings muſt be leſs than the proportion of children derived from each *marriage*; and the contrary muſt take place, where there is a decreaſe: and by Mr. King's computation, about one in an hundred and four perſons *marry*; the number of people in England being eſtimated at five millions and a half, whereof about forty-one thouſand annually *marry*.

In the diſtrict of Vaud in Switzerland, the married are very nearly a third part of the inhabitants.

Major Graunt and Mr. King diſagree in the proportions between males and females, the latter making ten males to thirteen females in London; in other cities and towns, and in the villages and hamlets, a hundred males to ninety-nine females; but major Graunt, both from the London and country bills, computes, that there are in England fourteen males to thirteen females; whence he juſtly infers, that the Chriſtian religion, prohibiting polygamy, is more agreeable to the law of nature than Mahometaniſm, and others that allow it.

This proportion of males to females Mr. Derham thinks pretty juſt, being agreeable to what he had obſerved himſelf. In the hundred years, for inſtance, of his own pariſh-regiſter of Upminſter, though the burials of males and females were nearly equal, being ſix hundred and thirty-three males, and ſix hundred and twenty-three females, in all that time; yet there were baptized ſeven hundred and nine males, and but ſix hundred and ſeventy-five females, which is 13 females to 13.7 males.

From a regiſter kept at Northampton for twenty-eight years, from 1741 to 1770, it appears, that the proportion of males to females that were born in that period is 2361 to 2288, or nearly 13.4 to 13. However, though more males are born than females, Dr. Price has ſufficiently ſhewn, that there is a conſiderable difference between the probabilities of life among males and females, in favour of the latter; ſo that males are more ſhort-lived than females; and as the greater mortality of males takes place among children, as well as among males at all ages, the fact cannot be accounted for merely by their being more ſubject to untimely deaths by various accidents, and by their being addicted to the exceſſes and irregularities which ſhorten life. Mr. Kerſeboom informs us, that, during the courſe of 125 years in Holland, females have, in all accidents of age, lived about three or four years longer than the ſame number of males.

In ſeveral towns of Germany, &c. it appears, that of 7270 married perſons who had died, the proportion of married men who died to the married women, was 5 to 2; and in Breſlaw for eight years, as 5 to 3. In all Pomerania, during nine years, from 1748 to 1756, this proportion was nearly 15 to 11. Among the miniſters and profeſſors in Scotland, twenty married men die to twelve married women, at a medium of twenty-ſeven years, or in the proportion of 5 to 31 ſo that there is the chance of 3 to 2, and in ſome circumſtances even a greater chance, that the [illegible] ſhall be the ſurvivor of a *marriage*, and no [illegible] this difference cannot be accounted for ma[illegible] exceſſive of age between men and their wive[illegible] among the proportionality of males. In the [illegible] Vaud, in Switzerland, it appears, that half the [illegible] do not die till the age of forty-ſix and upward[illegible] the males do not thirty-ſix. It is [illegible] remarkable fact, that, in the beginning of life, the [illegible] mortality among males is much greater than among [illegible]. From a table formed by Dr. [illegible] from a regiſter kept for twenty years [illegible] it appears, that

those who live to eighty, the major part, in the proportion of 49 to 32, are females. Mr. Deparcieux at Paris, and Mr. Wargentin in Sweden, have farther observed, that not only women live longer than men, but that married women live longer than single women. From some registers examined by Mr. Muret in Switzerland, it appears, that of equal numbers of single and married women between fifteen and twenty-five, more of the former died than of the latter, in the proportion of 2 to 1. With respect to the difference between the mortality of males and females, it is found to be much less in country parishes and villages than in towns; and hence it is inferred, that human life in males is more brittle than in females, only in consequence of adventitious causes, or of some particular debility, that takes place in polished and luxurious societies, and especially in great towns.

From the inequality, above stated, between the males and females that are born, it is reasonable to infer, that one man ought to have but one wife; and yet that every woman, without polygamy, may have a husband; this surplusage of males above females being spent in the supplies of war, the seas, &c. from which the women are exempt.

Perhaps, says Dr. Price, it might have been observed with more reason, that this provision had in view that particular weakness or delicacy in the constitution of males, which makes them more subject to mortality; and which consequently renders it necessary that more of them should be produced, in order to preserve in the world a due proportion between the two sexes. See EXPECTATION *of life*, and MORTALITY.

That this is a work of Providence, and not of chance, is well made out by the very laws of chance, by Dr. Arbuthnot; who supposes Thomas to lay against John, that, for eighty-two years running, more males shall be born than females; and, giving all allowances in the computation to Thomas's side, he makes the odds against Thomas, that it does not so happen, to be near five millions of millions of millions to one; but for ages of ages, according to the world's age, to be near an infinite number to one.

According to Mr. Kerseboom's observations, there are about 325 children born from 100 marriages.

Mr. Kerseboom, from his observations, estimates the duration of *marriages*, one with another, as in the following table.

Those whose ages, taken together, make		
40	live together between 24 and	25 years.
50	22	23
60	23	21

Phil. Transf. N° 468. sect. iii. p. 319.

Dr. Price has shewn, that on De Moivre's hypothesis, or that the probabilities of life decrease uniformly (see COMPLEMENT *of life*) the duration of survivorship is equal to the duration of *marriage*, when the ages are equal; or, in other words, that the expectation of two joint lives, the ages being equal, is the same with the expectation of survivorship; and, consequently, the number of survivors, or (which is the same, supposing no second *marriages*) of widows and widowers, alive together, which will arise from any given set of such *marriages* constantly kept up, will be equal to the whole number of *marriages*; or half of them (the number of widows in particular) equal to half the number of *marriages*. Thus, the expectation of two joint lives, both 40, is the third of 46 years, or their complement, i. e. 15 years and 4 months; and this is also the expectation of the survivor. That is, supposing a set of *marriages* between persons all 40, they will, one with another, last just this time, and the survivors will last the same time. In adding together the years which any great number of such *marriages*, and their survivorships, have lasted, the sums would be found to be equal. It is observed farther, that if the number expressing the expectation of single or joint lives, multiplied by the number of single or joint lives whose expectation it is, be added annually to a society or town, the sum gives the whole number living together, to which such an annual addition would in time grow: thus, since 10, or the third of 27, is the expectation of two joint lives, whose common age is 29, or common complement 57, twenty *marriages* every year between persons of this age would, in fifty-seven years, grow to 20 times 19, or 380 *marriages* always existing together. The number of survivors also arising from these *marriages*, and always living together, would, in twice 57 years, increase to the same number. Moreover, the particular proportion that becomes extinct every year, out of the whole number constantly existing together of single or joint lives, must, wherever this number undergoes no variation, be exactly the same with the expectation of those lives, at the time when their existence commenced. Thus, if it were found that a nineteenth part of all the *marriages* among any body of men, whose numbers do not vary, are dissolved every year by the deaths of either the husband or wife, it would appear, that 19 was, at the time they were contracted, the expectation of these *marriages*. Dr. Price observes, that the annual average of weddings among the ministers and professors in Scotland, for the last twenty-seven years, has been thirty-one; and the average of married persons, for seventeen years, ending in 1767, had been 667. This number, divided by 31, gives 21½, the expectation of *marriage* among them; which, he says, is above 2½ years more than the expectation of *marriage* would be, by Dr. Halley's rule, on the supposition, that all first, second, and third *marriages*, may be justly considered as commencing, one with another, so early as the age of thirty; and he has proved, that the expectation of two equal joint lives is to the expectation of a single life of the same age as 2 to 3: consequently, the expectation of a single life at 30, among the ministers in Scotland, cannot be less than 32.25. If we suppose the mean ages of all who marry annually to be 33 and 25, the expectation of every *marriage* would be 19 years; or one with another they would be all extinct in 19 years; the *marriages* which continue beyond this term, though fewer in number, enjoying among them just as much more duration, as those that fail short of it enjoy less. But it appears from the observations and tables of Mr. Muret, that, in the district of Vaud (dividing half the number of married persons, viz. 38,328, by the annual medium of weddings, viz. 868) the expectation of *marriage* is only 23½ years: so much higher are the probabilities of life in the country than in towns, or than they ought to be, according to De Moivre's hypothesis. Price's Obs. &c. See EXPECTATION *of life*, LIFE-*annuities*, and SURVIVORSHIP.

MARRIAGE, *marriagium*, in *Law*, signifies not only the lawful joining of man and wife, but also the right of bestowing a ward, or a widow, in *marriage*; as well as the land given in *marriage*.

MARRIAGE, *dissolution of*. See DIVORCE.

MARRIAGE, *forcible*. See FORCIBLE *marriage*.

MARRIAGE, *frank*. See FRANK.

MARRIAGE, *inticitation of*, in *Law*, is one of the first and principal matrimonial causes, when one of the parties boasts or gives out, that he or she is married to the other, whereby a common reputation of their matrimony may ensue. On this ground the party injured may libel the other in the spiritual court; and unless the defendant undertakes and makes out a proof of the actual marriage, he or she is enjoined perpetual silence on that head; which is the only remedy the ecclesiastical courts can give for this injury. Blackst. Comm. vol. iii. p. 93.

MARRIAGE *settlement*, is a legal act, previous to *marriage*, whereby a JOINTURE is secured to the wife after the death of the husband. These settlements seem to have been in use among the ancient Germans, and their kindred nations the Gauls. Of the former Tacitus gives us this account: *Dotem non uxor marito, sed uxori maritus offert: interest parentes & propinqui, & munera probant.* De Mor. Germ. c. 18. And Cæsar, De Bell. Gallic. lib. vi. c. 18. has given us the terms of a *marriage* settlement among the Gauls, as nicely calculated as any modern jointure. *Viri, quæ tantas pecunias ab uxoribus dotis nomine acceperunt, tantas ex suis bonis, æstimatione facta, cum dotibus communicant. Hujus omnis pecuniæ conjunctim ratio habetur, fructusque servantur. Uter eorum vita superavit, ad eum pars utriusque cum fructibus superiorum temporum pervenit.* The dauphin's commentator supposes that this Gaulish custom was the ground of the new regulations made by Justinian, Nov. 97. with regard to the provision for widows among the Romans; but surely there is as much reason to suppose, says judge Blackstone, that it gave the hint for our statutable jointures. Comm. vol. ii. p. 138.

See an excellent *marriage* settlement by Blackstone, in the appendix to the second volume of his Commentaries.

MARRIAGE, *duty of*, is a term used in some ancient customs, signifying an obligation on women to marry.

To understand this, it must be observed, that old maids, and widows about sixty, who held fees in body, or were charged with any personal or military services, were anciently obliged to marry, to render those services to the lord by their husbands, or to indemnify the lord for what they could not do in person. And this was called *duty* or *service of marriage*.

MARROQUIN, vulgarly MOROCCO-*leather*. See MOROCCO.

MARROW, a soft oleaginous substance contained in the cavities of the bones.

All the bones of the body, which have any considerable thickness, have either a large cavity, or elſe they are ſpongeous, and full of little cells: in both the one and the other is an oleaginous ſubſtance, called *marrow*, contained in proper veſſels or membrances, which open into one another.

This ſubſtance, while it lies in the cavities of the large bones, is more particularly called *marrow*; when diſperſed in the ſmall cellulous cavities, it is commonly called the medullary juice. The *marrow* of the large hollow bones is a maſs compoſed of an infinity of ſmall veſicles, or membranous cells, joined together, and communicating with each other, furniſhed with blood-veſſels and nerves, and filled with a fine ſweet oily matter. All theſe cells are ſurrounded by a fine membrane, which, like an internal periоſteum, ſticks cloſe to the inner ſurface of the bone, by means of an infinite number of capillary veſſels, and of ſeveral other kinds of very ſmall filaments. The reticular ſubſtance of the bones runs through this medullary maſs, and, as it were, interſtands it, and by this means ſuſtains it in the middle of the great cavities. The *marrow* of the cellulous or cavernous ſubſtance of the bones, is divided by ſmall bony ſepta or plates, and by filaments of the reticular ſubſtance of the bones into a vaſt number of veſicles or membranous cells, which line the bony cells, and communicate with each other.

This cellular *marrow* in the cavernous texture of ſome bones, differs from that in the great cavities of others both in colour and conſiſtence; it is liquid, and of a red colour throughout; while the other is more ſolid, and is only red on its ſurface. This difference is owing to the blood-veſſels which run through each membranous cell, whereas the *marrow* in the great cavities ſeems to be furniſhed with them in the common membrane only. Many of thoſe medullary cells are likewiſe divided by the bony filaments of the cavernous ſubſtance; and theſe ſmall filaments, as well as thoſe of the reticular texture, are covered by portions of the medullary membrane, as by a periоſteum.

The medullary membranes may be ſeparated from the liquor which they contain, by ſteeping the whole maſs in very hot water, and afterwards compreſſing it by gentle degrees. But it is to both theſe ſubſtances, taken together, that the anatomiſts give the common name of *marrow*, not to either of them taken ſingly. The medullary membrane is very ſenſible, as is likewiſe the juice, which is neceſſary to be obſerved, to underſtand properly what is meant by the ſenſibility of the *marrow*. The *marrow*, by its liquid and unctuous part, renders the bones in ſome meaſure pliable, and leſs brittle, as it continually pervades their ſubſtance in ſmall degrees: this continues to old age, and then the bones, being deprived of their *marrow*, become very brittle.

In the bones of the oſſa innominata, there are no internal large cavities; but their ſubſtance being cellulous or cavernous, they contain no medullary maſs, but their cells are all moiſtened with a medullary juice, which diſtils inceſſantly through the membrane with which they are lined. In the os femoris the *marrow* lies in a large maſs, in the middle cavity of the bone, and in ſmall diſtinct cluſters in the cells of each extremity. The firſt is penetrated at different diſtances by the bony filaments, and is thereby ſuſtained in all violent motions and ſhocks, as running, leaping, and the like. In the bones of the leg the diſpoſition is exactly the ſame; and in the bones of the foot, the *marrow* is ſuitable to their internal ſtructure, and is lodged in moleculæ, in the cavernous portions, and in maſſes in thoſe which have cavities to receive them. Thus the *marrow* of all the tarſal bones is diſperſed in moleculæ, becauſe their internal ſtructure is ſpongy. In the metatarſal bones, and firſt phalanges of the toes, it is diſpoſed in the ſame manner as in the tibia and fibula, that is, it lies in moleculæ in the extremities, and in their middles in greater or leſſer maſſes, according to the ſizes of the cavities. In the other phalanges, which are entirely ſpongy, it is accordingly diſpoſed in moleculæ. In the vertebræ, ſternum, and ribs, the internal ſtructure of all which is cellular and ſpongy, the *marrow* is contained only in ſmall ſeparate portions, and is no other than a red medullary juice. The bones of the head alſo being in like manner cellular in their internal ſtructure, contain alſo their *marrow*, in like manner, in diſtinct portions, and lying in membranous cells in the diploe. Winſlow's Anatomy, p. 118, 136, 150, 152.

The tranſpiration of the unctuous matter of the *marrow* is not confined to the time of the animal's life, it is even carried on in the dead carcaſe, and is one great obſtacle to the whitening and cleaning the bones in a ſkeleton; for if there be not an opening made at one end of a bone, and the *marrow* waſhed out of the whole bone at this aperture, by means of proper liquors injected with a ſyringe, the bone, though made ever ſo white at firſt, will certainly turn yellow afterwards, by this tranſpiration of the *marrow* contained within it, which certainly happens on the leaſt heat of the weather, or otherwiſe. For this reaſon it is alſo, that the workmen who uſe bones always cut them longitudinally in two, and take out all the *marrow*, and even all the ſpongy ſubſtance of the bone, which might be ſuppoſed to contain it, otherwiſe they know that the heat of any one's hand will turn their works yellow, though ever ſo white when firſt made. It is to be obſerved, that there are in the hollow bones ſeveral ſmall apertures, through which there paſs blood-veſſels, which go from the membrane including the *marrow*; whence it appears that the bones are indeed nouriſhed from within as well as from without, though that be not by the *marrow*, but by the blood-veſſels only: thus the [illegible] bles of the ſkull are evidently nouriſhed; the [illegible]bie by the veſſels of the pericranium, and the [illegible] by the branches of thoſe veſſels which are ſpread [illegible] dura mater.

It has been ſuppoſed that the quantity of *marrow* increaſed in the bones according to the increaſe of the moon; but this has been found a wholly erroneous opinion, the increaſe of the *marrow* in all the bones depending on the quantity of nouriſhment, and the ſtate of reſt which the creature is allowed.

The ſenſation of the *marrow* has been a point very variouſly ſpoken of. When a limb has been taken off, and the *marrow* is left bare, if any thing touch it roughly, the patient feels an exquiſite pain. Some had ſuppoſed that this ſenſation might rather ariſe from the membranes, than from the ſubſtance of the *marrow*: this, however, was put beyond all doubt by a curious, though very cruel operation, performed before the Paris academy. A living animal had its leg taken off before the academy, and the end of the bone left very bare; the membranes were all carefully removed, to the exquiſite pain and torture of the creature; and when the pain of this was over, the end of a ſtyle was plunged into the *marrow*, without touching any other part whatever, and the creature, on this, expreſſed as violent a ſenſation of pain as from any of the former operations. This was repeated ſeveral times, and always with the ſame event; ſo that it is very evident that the *marrow* is, in its natural ſtate, highly ſenſible of pain; and how much more may it be ſo in diſtempered bodies!

The ancients ſuppoſed that the *marrow* ſerved for the nouriſhment of the bones; and their reaſons for believing it were, that they ſaw no blood-veſſels enter the ſubſtance of the bones, by which they could be nouriſhed, all the veſſels of that kind, which they could diſcover, going directly into their cavities, where the blood they contained ſeem to undergo a ſort of concoction, which converted it into *marrow*, and by that means rendered it fit nutriment for the bones; and they obſerved, in proof of this, that the longer any bone was, and the more violent uſes it was intended for, the larger was its cavity for containing this nutritious matter.

Theſe reaſons, though they carry a great ſhew of probability, yet are eaſily refuted by accurate obſervation. We ſee, in young ſubjects, a vaſt number of blood-veſſels diſtributed through the ſubſtance of the bones, the texture of which, at that time, is lax and ſpongy. It is alſo to be obſerved, that there are many bones in the human body, as well as in brutes, which, according to this ſyſtem, could not be nouriſhed at all, ſince they contain no *marrow*. Of this kind alſo are the horns of deer, and many other creatures, which, though they contain no *marrow*, yet grow very vigorouſly. There are alſo other bones which are hollow, yet are only clothed with a glandulous membrane; ſuch are the cavities between ſeveral parts of the two tables of the ſkull; and in the elephant, the foliaceous bones, which are in the place of the diploe, contain no *marrow*, and are only covered with a membrane, which has ſeveral blood-veſſels ſcattered through it. The hollows of thoſe bony ſubſtances alſo which compoſe the claws of crabs, lobſters, and the like, contain no *marrow* [illegible] only the muſcles, whoſe office it is to move thoſe [illegible] theſe grow, and are nouriſhed, as well [illegible] which contain ever ſo much *marrow* in [illegible] ſine, it may be well concluded, that [illegible] the uſe of containing *marrow*, that the bon[illegible] but merely that they may be lighter, [illegible]tion. Mem. Acad. Par. 1700.

Obſervation gives abundant [illegible] great quantity of the *marrow* continu[illegible] through the whole ſubſtance of the bones, [illegible] is of no uſe, though not in the [illegible] weſerving the bones, its oily and [illegible] ſerving the ſmall fibres of which the bone [illegible] ſoftening and rendering them [illegible]

more supple, soft, and flexile, and consequently the whole bone much less liable to break.

MARRUBIASTRUM, in *Botany*. See IRON-*wort*.

MARRUBIUM, in *Botany*. See HOREHOUND.

MARS, in *Mythology*, the god of war, the son of Jupiter and Juno, or, as Ovid tells the story, of Juno alone; she being displeased that Jupiter should have a daughter, Minerva, without female aid: being therefore a son of discontent, he was made the god of war and strife. He had a sister called BELLONA, the goddess of war.

He had for his priests the *salii* and *flamines*, who from him were called *Martiales*. They sacrificed asses to him, on account of the harsh dissonance of their voice. The vulture was a bird sacred to him, from their always flying to those places where armies are going to engage, and his chariot is to be expected. The usual attributes of *Mars* are the helmet and spear, which he does not lay aside, even when he is going on his amours. Several of the old Roman poets of the first age speak of a wife of *Mars*, called Nerienе, signifying, according to some, *mildness*, and given to him in order to soften and humanize the roughness of his temper; but we find no traces of her in their later poets. The temples of *Mars* were of the Doric order, and usually placed without the walls; hereby denoting that this deity was to preserve the walls from the perils of war.

MARS, in *Astronomy*, one of the five planets, and of the three inferior ones; its place being between the earth and Jupiter.

Its character is ♂. Its mean distance from the sun is 1524 of those parts, whereof the distance of the sun from the earth is 1000; its EXCENTRICITY 1415, and its real distance 145,914,148 miles; the inclination of its orbit, that is, the angle formed by the plane of its orbit with the plane of the ecliptic, 1 degree 52 minutes; the periodical time, in which it makes its revolution round the sun, is 686 days 23 hours; which is the length of his year, and contains 6693 of his days; every day and night together being 40 minutes longer than with us; and its revolution about its own axis is performed in 24 hours 40 minutes.

For the diameter of *Mars*, its denſity, the force of gravity on its ſurface, &c. ſee DIAMETER, DISTANCE, and PLANETS.

Its parallax, according to Dr. Hook, and Mr. Flamſteed, is ſcarce 30 ſeconds.

In the acronical riſing of this planet, that is, when it is in oppoſition to the ſun, it is found five times nearer to us, than when in conjunction with him; and, therefore, he appears to much bigger and brighter at one time than another.

Dr. Hook, in 1665, obſerved ſeveral ſpots in *Mars*; which having a motion, he concluded the planet to turn round its center. In 1666, M. Caſſini obſerved ſeveral ſpots in the two faces or hemiſpheres of *Mars*, which, by continuing his different obſervations very diligently, he found to move by little and little from eaſt to weſt, and to return, in the ſpace of 24 hours 40 minutes, to their former ſituation. Theſe obſerrations were repeated in 1672, and confirmed by Miraldi in 1704, and 1719. Whence both the motion and period, or natural day, of that planet, were determined.

Mars always appears with a ruddy, troubled light; whence we conclude, it is encompaſſed with a thick, cloudy atmoſphere; which, by diſturbing the rays of light in their paſſage and re-paſſage through it, occaſion that appearance.

Mars, having his light from the ſun, and revolving round it, has an increaſe and decreaſe like the moon: it may alſo be obſerved almoſt bihected, when in its quadratures with the ſun, or in his perigeon; but never is ſeen cornicular, or falcated, as the inferior planets; which both ſhews that his orbit includes the earth's within it, and that he ſhines not by his own light. The phaſes of *Mars* were firſt diſcovered by Galileo.

This planet's diſtance from the ſun is to the diſtance of the earth and ſun, as 13 to 12; ſo that a man, placed in *Mars*, would ſee the ſun's diameter leſs by one third than it appears to us; and, conſequently, the degree of light and heat, which *Mars* receives from the ſun, is leſs than that received by the earth, in the proportion of 4 to 9. This proportion, however, will admit of a ſenſible variation, on account of the great excentricity of this planet. Though the period or year of this planet, 22 has been already obſerved, nearly twice as long as our's; and his natural day, or the time in which the ſun appears above his horizon (leaving out the conſideration of twilight), is almoſt every where equal to his night; yet it appears, that, in one and the ſame place on his ſurface, there will be but very little variety of ſeaſons, or ſcarce any difference of ſummer and winter; and the reaſon is, that the axis of his diurnal rotation is nearly at right angles with the plane of his orbit. It will be found, notwithſtanding, that places ſituate in different latitudes, that is, at different diſtances from his equator, will have very different degrees of heat, on account of the different inclination of the ſun's rays to the horizon; as it is with us, when the ſun is in the equinoxes, or in the tropics.

From this conſideration, Dr. Gregory endeavours to account for the appearance of the faſciæ in *Mars*, which are certain ſwathes or fillets ſeen in this planet, and poſited parallel to his equator: for, as among us, the ſame climate has, at different ſeaſons, very unequal degrees of heat; but, as in *Mars* it is otherwiſe, the ſame parallel having always a pretty equable degree of heat, it follows, that theſe ſpots may probably be formed in *Mars*, or in his atmoſphere, as ſnow and clouds are in our's, viz. by the conſtant different intenſities of heat and cold in the different parallels; and ſo come to be extended in circles or belts parallel to his equator, or the circle of his diurnal revolution. And this ſame principle may, perhaps, ſolve the phenomenon of Jupiter's belts; that planet, like *Mars*, having a perpetual equinox.

Beſides the ruddy colour of *Mars*, we have another argument of his being encompaſſed with an atmoſphere; and it is this: that, when any of the fixed ſtars are ſeen near his body, they appear extremely obſcured, and almoſt extinct. If this be the caſe, an eye placed in *Mars* would ſcarce ever ſee Mercury, unleſs, perhaps, in the ſun at the time of conjunction, when Mercury paſſes over his diſk, as he ſometimes appears to us, in form of a ſpot. A ſpectator in *Mars* will ſee Venus about the ſame diſtance from the ſun, as Mercury appears to us; and the earth as big as Venus appears to us, and never above 48 degrees from the ſun; and when the earth is found in conjunction with, and very near, the ſun, he will ſee the earth appear horned, or falcated, and its attendant the moon of the ſame figure, and, at its utmoſt diſtance from the earth, not above 15 minutes of a degree, though they are really two hundred and forty thouſand miles aſunder. This planet being but a fifth part ſo big as the earth, if any moon attends him, ſhe muſt be very ſmall, and has not yet been diſcovered by our beſt teleſcopes.

MARS, among *Chemiſts*, ſignifies IRON; becauſe imagined to be under the influence of that planet.

Phyſical writers hold iron preferable, for all medicinal purpoſes, to STEEL, which is only a more hardened, compact iron, made ſo by art; whereby it is rendered more unfit to yield thoſe principles or parts in preparation, which the phyſician requires to be drawn out.

MARS *ſaccharatus*. See IRON.

MARS *ſulphuratus*. See IRON.

Crocus MARTIS, ruſt of iron. See CROCUS *martis*.

MARS, *cryſtals of*. See CRYSTAL.

MARS, *tree of*, *arbor Martis*. See ARBOR.

MARS, *games of*, *ludi Martiales*, were combats inſtituted at Rome in honour of the god *Mars*.

They were held twice in the year; once in the circus, on the fourth of the ides of May; and a ſecond time on the firſt of Auguſt. Theſe latter were eſtabliſhed ſome time after the other, in memory of the dedication of the temple of *Mars*, on that day. Theſe games conſiſted in courſes of horſes, and combats with wild beaſts. Germanicus is ſaid to *have* killed two hundred lions in the circus, on theſe occaſions. See FIELD *of Mars*.

MARSH, in *Agriculture*, &c. See MARSH *lands*.

MARSH, or *water elder*, in *Botany*. See WAYFARING-*tree*.

MARSH-*fever*, is a ſpecies of BILIOUS *fever*.

Thoſe ſeized with the *marſh-fever* are tormented with a burning heat, and violent head-ach. They complain likewiſe of intenſe thirſt, aching of the bones, a pain of the back, great reſtleſs and inquietude; and frequently of a nauſea, ſickneſs, or a pain about the pit of the ſtomach; which is ſometimes attended with a vomiting of green or yellow bile, of an offenſive ſmell. The head is ſometimes ſo ſuddenly and violently affected, that without any previous complaint, the patients run about in a wild manner, as if they were mad; and would throw themſelves out of windows, or into the water, if not prevented. Pringle.

MARSH-*mallow*. See MALLOW.

MARSH-*orchis*, *mentorchis*. See *Bog*-BEAN.

MARSHAL, or MARESCHAL, *mareſcallus*, primarily denotes an officer, who has the care of the command of horſes.

Nicod derives the word from *palemarchus*, *maſter of the camp*; Matthew Paris from *Martis ſeneſchallus*. In the old Gauliſh language, *march* ſignified *horſe*; whence *marechal* might ſignify him who commanded the cavalry. Spelman, Skinner, and Menage, derive it from the German *mar*, *marre*, a *mare*, or even a horſe, and *ſchall*, *ſervant*; which makes ſome imagine the title was firſt

given

given to farriers, or those who shod and bled horses; and that, in succession of time, it passed to those who commanded them. Palquier makes four several derivations for the four several kinds of *marshals* in use among the French; viz. *marshals* of France, *marshals de camp*, *marshals de logis*, or quarter-masters, and farriers, who are also called by the name of *marshals*. The third he derives from *marche*, or *marcher*, *to march*, *limit*; and the last from *maire*, *mayor*, and *chal*, *horse*.

Earl-MARSHAL *of England*. See EARL-*marshal*.

Knight-MARSHAL, or MARSHAL *of the king's house*, is an officer, whose business, according to Fleta, is to execute the commands and decrees of the lord steward, and to have the custody of prisoners committed by the court of verge. Under him are six *marshal's* men, who are properly the king's bailiffs, and attest in the verge of the court, when a warrant is backed by the board of green-cloth. The COURT where causes of this kind, between man and man, are tried, is called the *Marshalsea*, and is under the *knight-marshal*.

This is also the name of the prison in Southwark; the reason of which may probably be, that the *marshal* of the king's house was wont to sit there in judgment, or keep his prison.

There are some other inferior officers of this name; as,

MARSHAL of the justices in eyre.

MARSHAL of the king's bench, who has custody of the prison called the king's bench in Southwark.

This officer gives attendance upon the court, and takes into his custody all prisoners committed by the court; he is fineable for his absence, and non-attendance incurs a forfeiture of his office. The power of appointing the *marshal* of the king's bench is in the crown. 27 Geo. II. c. 17.

In Fleta, mention is also made of a *marshal of the exchequer*, to whom the court commits the custody of the king's debtors, &c.

MARSHAL, or MARESCHAL, of France, is the highest dignity of preferment in the French armies. The dignity of *marshal* is now for life, though, at its first institution, it was otherwise. They were then only the king's first ecuyers under the constable, but in time they became the constable's lieutenants in the command of the army, the constable himself being then become captain-general. At first they were but two in number, and their allowance was but five hundred livres per annum in time of war, and nothing in time of peace; but in the reign of Francis I. a third was added; Henry II. created a fourth. Since it has been various; Lewis XIV. increased it to twenty. Their office at first was, to *marshal* the army under the constable, and to command in his absence.

They did then what the *marshals de camp* do now; to which last they have given their title, and the least considerable part of their authority.

The first *marshal* does the office of constable in an assembly of the *marshals*.

Arch-MARSHAL. See ARCH.

Clerk-MARSHAL. See CLERK.

Field-MARSHAL. See FIELD-*marshal*.

Provost-MARSHAL. See PROVOST.

MARSHALLING a *coat*, in *Heraldry*, signifies the due and proper joining of several coats of arms belonging to distinct families in one and the same shield, or escutcheon; together with their ornaments, parts, and appurtenances.

MARSHALSEA. See COURT *of Marshalsea*.

MARSHY, or MARSH *lands*, a name given by our farmers to a sort of pasture-land, or grazing-ground, which lies near the sea, rivers, or fens.

As to lands lying near rivers, the great improvement of them is their being overflowed; which brings the soil of the uplands upon them, so that they need no other manuring, though kept constantly mowed. The great inconveniency of these lands, is their being subject to floods, which high hills near the sides of rivers, and the long course of them, bespeak to be frequent. And though the richest land generally lies near such rivers, yet there is the greatest danger of the crops being spoiled, especially when they are not inclosed; and therefore cannot be fed with cattle. This, when feeding bears any thing of a price, would be the very best way of managing these uncertain lands; and inclosing them would be highly beneficial on this account.

The *marsh*-lands in Lincolnshire, and many other parts of England, produce a sort of grass, which feeds sheep in a better manner than that of almost any other land, in regard to their size, and the quantity of wool. The sheep about Grimsby, and some other places in this county, produce such lusty wool, or, as they call it, wool of so large a staple, that three or four fleeces usually make a tod of twenty-eight pounds weight. Several hundred loads of this wool are yearly carried from these places to Norfolk, Suffolk, and other parts of the kingdom, for the cloth-manufacturers. They send this in large packs, which they call pockets, each containing about five and twenty hundred weight. Philos. Trans. N° 223.

When *marsh*-lands lie flat, it is necessary for the owner to keep all the water he can from them. The sea-water, in particular, is to be kept from them as much as possible; and this is usually done at a very great expence, by high banks and walls.

Two things greatly wanting in these lands in general, are good shelter for the cattle, and fresh water. The careful farmer may, however, in a great measure, obviate these by digging, in proper places, large ponds to receive the rain water, and by planting trees and hedges in certain places toward the sea, where they may not only afford shelter to the cattle, but keep off the [illegible], which often will eat off the tops of [illegible] in those places, and make it look as if it had [illegible]. These lands often cattle the sooner [illegible] preserve sheep from the rot. It would be a great [illegible] to them, if there were raised, in the middle [illegible] very large *marsh*, banks of earth in a cross, or in form of two semicircles, and these planted with trees; these would serve as a shelter for cattle, let the wind blow from what quarter it would, and would soon repay the expence of making.

There are, in different parts of England, very large quantities of land upon the sea-coasts, that would be worth taking in, though no one yet has thought of doing it. The coasts about Holland, Spalding, and many other parts of Lincolnshire, give frequent instances of this, where the sea falls from the land, so that on the outside of the sea-walls, on the ouse, where every tide the salt-water comes, there grows a good deal of good grass, and the ouse is firm to ride upon, when the water is upon it.

This ouse, when taken in, hardly sinks any thing at all, and they dig the walls from the outside of it, all the earth they are made of, being taken from thence, and the sea, in a few tides, filling it up again: and though the sea, at high water, comes only to the foot of the bank, yet once in a year or two, some extraordinary tides go over the banks, though they are ten feet high. These banks are fifty feet broad at the bottom, and three feet at the top; and the common price of making them is twenty-six shillings a pole, the earth being all carried in wheel-barrows, and the face toward the sea, where the greatest slope is, being turfed. Mortimer's Husbandry. See FEN and DRAINS, &c.

It is to be observed, that neither coasts, nor even large inundations, where the water is deep, are nearly so dangerous in regard to people's health, or exhale so much noxious vapour, as *marshy* grounds, or meadows that have been once floated, and but lately drained; and that fields, though dry in appearance, may nevertheless be moist by the transpiration of subterraneous water.

By this exhalation, as well as by that of ditches and canals, in all which innumerable plants and insects die and rot, the atmosphere is filled, especially during the latter part of summer and autumn, with moist, putrid, and insalubrious vapours. Add to this, that *marshy* countries being low, and without hills to receive the winds, or direct them in streams upon the lower grounds, the air is apt to stagnate and corrupt. The common water too, being either collected from rains, and preserved in cisterns, or drawn from shallow wells, is, in hot and dry seasons, soon corrupted; so that every thing conspires, in summer, not only to relax the solids, but to dispose the humours to putrefaction.

In *marshy* countries rainy and moist seasons differ greatly; since intense and continued heats occasion the greatest moisture in the atmosphere, by the immense exhalations they raise; whereas frequent showers, during the hot season, cool the air, check the excess of vapours, dilute and refresh the corrupted stagnating water, and precipitate all putrid and noxious effluvia. But if heavy rains, in the beginning of summer, are succeeded by great and uninterrupted heats, those rains, by overflowing the meadows, serve only for matter of more exhalation, and to make the season more sickly, and the distempers more fatal.

The epidemic of the hot [illegible] great endemic of *marshy* countries, is a [illegible] remitting nature, commonly of a tertian [illegible] kind; which in the damper places, and [illegible] appears in the form of a double tertian, [illegible] putrid, or even an ardent fever.

Arabian countries are [illegible] more than any others, to the cholera [illegible] and a kind of scurvy, peculiar to a moist [illegible], the symptoms of which [illegible] sea-scurvy, that they may be accounted [illegible]; the exhalations

halations of the canals and *marshes*, in hot weather, acting like the vapour which rises from the bildge-water of a ship. Id. ibid. p. 6, seq.

As to the diet necessary in moist places, it may be observed in general, that those who can afford to live above the common rate, keep freest from the diseases of the *marshes*. For such climates require dry houses, the apartments raised from the ground, proper exercise without labour in the sun, or in the evening damps, a just quantity of vinous liquors, and victuals of good nourishment. Without such helps, not only strangers, but the natives themselves, are extremely sickly, after hot and close summers. Pringle's Obs. on Diseases of the Army.

It has been sufficiently demonstrated, by Dr. Priestley, and others, that air which arises from stagnant and putrid water, or which has been for some time in contact with it, must be very unfit for respiration; and, therefore, that the neighbourhood of putrid *marshes*, on account of the noxious quality of the effluvia issuing from them, must be exceedingly insalubrious. See EFFLUVIA.

MARSILEA, in *Botany*, a name given by Linnæus to a genus of the *cryptogamia* class of ferns: the male flowers of which are above the leaf; and the female part of the fructification consists at the root of a roundish fruit, composed of four capsules.

MARSUIN, in *Zoology*, a name by which many have called the *phocæna*, or PORPESSE, a fish too often confounded with the dolphin.

MARSUPIALE, in *Natural History*, a name given by Tyson to the creature commonly called the *possum*, or OPOSSUM. The peculiar distinction of this creature from all others, is its having a pouch, or *marsupium*, under its belly, into which it receives its young in time of danger: whence the name.

MARSUPIALIS *musculus*, in *Anatomy*, a name given by Cowper, and some others, to a muscle on the thigh, called also by some, BURSALIS. It is that muscle, called by Albinus, Winslow, and the generality of modern authors, OBTURATOR *internus*.

MARSUPIUM *carneum*, in *Anatomy*, a name given by Spigelius, Cowper, and some other authors, to certain muscles of the thigh, called by the French writers, *les petit jumeaux*, and by Albinus, *gemini*. Vesalius does not esteem them separate muscles, but calls them only *carneæ portiones decimo femur moventium musculo attenuatæ*, fleshy portions affixed to the tenth muscle of the thigh. Riolan, who calls the *pyriformis*, or pyramidal muscle of the thigh, the *quadrigeminus*, or *quadrigeminus prior*, calls these the *quadrigemini secundi et tertii*. They are sometimes distinct, sometimes they grow together.

MART, denotes a great FAIR or MARKET, for selling of goods, holden every year.

MART, *letters of*. See LETTERS.

MARTAGON, in *Botany*, a name given to several species of LILY.

MARTEAU, the name given by French naturalists to a peculiar species of OYSTER, called also *malleum* by others. It is one of the most curious shells in the world. Its figure is that of a hammer, with a very long head, or rather of a pick-ax. It has a body of moderate thickness, and two long arms. It is of a brownish colour, with a beautiful tinge of a violet-blue. Notwithstanding the strange shape of these shells, they close very exactly.

MARTIAL is sometimes used to express preparations of iron, or such as are impregnated therewith; as the *Martial* regulus of antimony, &c.

MARTIAL *court*. See COURT *martial*.

MARTIALE *bezoardicum*. See BEZOARDICUM.

MARTIAL *law* is the law of war, depending upon the arbitrary, but just power and pleasure of the king, or his lieutenants. The king, though in times of peace he makes no laws, but by the consent of his parliament; yet, in war, uses absolute power over the soldiery: though even this power hath been vested, of late years, in the king, or his generals of the army, by act of parliament, and under particular restrictions too.

Martial law, says sir Matthew Hale, is in reality no law, but something indulged, rather than allowed as law. The necessity of order and discipline in an army is the only thing that can give it countenance; and therefore it ought not to be permitted in time of peace, when the king's courts are open for all persons to receive justice, according to the laws of the land. The petition of RIGHT enacts, that no soldier shall be quartered on the subject without his own consent; and that no commission shall issue to proceed within this land according to *martial* law. See *Martial* COURT.

MARTIALES *flores*. See FLORES *martiales*.

MARTICHORA, in *Natural History*, the name given by the ancient Greeks to the animal which we call the MANTICHORA or *man-tiger*.

MARTIS *campus*. See CAMPUS and FIELD.

MARTIN, or *martlet*, in the *History of Quadrupeds*, the name of a creature of the weasel-kind, being the MUSTELA *martes* of Linnæus, with cloven feet, body of a deep yellow colour approaching to black, and whitish throat. There are two species of this creature, the one called the *martes abietum*, or fir-*martin*; the other, the *martes fagorum*, or beech-*martin*. The beech-*martin* is distinguished from the other by having a larger and blacker tail, and being all over of a darker colour, and by being white on the throat, whereas the others are yellow; but the species are scarce kept up distinct, the creatures mixing with one another in the breed. When distinct, the beech-*martin* is found to be a much tamer creature than the other, and may be kept about houses like a cat; and often lives of its own accord about houses, and among old walls. Their skins make a valuable fur; and that of the fir-*martin*, or yellow kind, is much the most valuable: prodigious numbers of their skins being annually imported from Hudson's Bay and Canada.

The *martin* is of the size of a cat, but longer bodied; its legs also are shorter, and its claws less sharp, and shorter. Its whole body is covered with hair of a yellowish black, except only the throat, which, in the beech-*martin*, or rarer kind, is white; and in the wild kind, or fir-*martin*, yellow. Its teeth are sharp and strong, and the dog-teeth, in particular, stand out a great way.

The beech-*martin*, with us, inhabits woods, makes its lodge in the hollows of trees, and brings from four to six young at a time. It makes great havock among poultry, game, &c. and will eat mice, rats, and moles.

The pine or fir-*martin* inhabits the north of Europe, Asia, and America; and is found also in Great Britain, particularly in Scotland; where it lodges in the fir-forests, building its nest at the top of the trees.

The *martin* leaves so strong a scent, that the hounds, when out in a morning, will often take it, and make a noble cry. The chace, in this case, is very good while it lasts, but it is very perplexed; for the creature is not able to run long, and when she is tired, she gets up into a tree; the hounds often lose her on this occasion; but if she is spied up in the tree, she is to be hunted down with sticks, &c. When killed, the hounds are not suffered to eat her flesh, for it is unwholsome. See *Tab.* III. *of Quadrupeds*, N° 33.

MARTIN, in *Ornithology*. See SWALLOW.

MARTIN, *Free*, in *Zoology*, is a name given in this country to a cow-calf, east at the same time with a bull-calf, which is a kind of HERMAPHRODITE; that is never known to breed, nor to discover the least inclination for the bull: nor does the bull ever take the least notice of this animal. It has all the external marks of a cow-calf, viz. the teats, and the external female parts, called by farmers the bearing. When these animals are preserved, it is not for propagation, but for all the purposes of an ox or spayed heifer, viz. to yoke with the oxen, and to fatten for the table. They are much larger than either the bull or the cow, and the horns grow larger, being very similar to the horns of an ox. The bellow of the free *martin* is like that of an ox; and the meat resembles that of the ox or spayed heifer; being generally finer than that of the bull or cow; and it is more susceptible of growing fat with good food. Mr. Hunter has anatomically described three animals of this kind, in the Phil. Trans. vol. lxix. part i. p. 289. &c.

MARTINAZZO, in *Ornithology*, the name of a species of water-fowl, of the larus or GULL kind, the *larus marinus* of Linnæus, and called, by the Dutch, the burgomaster of Greenland; by the Cornish people, the *waggell*, or the *great grey-gull*. It is a large bird, usually weighing from two to four pounds. It is all over of a mottled colour of brown, grey, and white; but is much darker on the back than on the belly. The back and wing-feathers are all brown in the middle, and grey at the edges; but those of the rump are mostly white; the legs are of a dirty white. They say that this gull will follow the smaller lari, and persecute and terrify them till they void their food in excrements half digested, which he afterwards picks up, esteeming it better than fresh food; and on this account it is sometimes called the *dung-hunter*.

MARTINGALE, invented by Evangelista, an eminent horseman of Milan; a thong of leather fastened at one end to the girths under the belly of an horse, and at the other end to the bit, or, which is the better way, to a thin mouth-piece of its own, to hinder him from rearing, or tossing up his head. It is also of service when the

horſe bears upon the hand, and his head is uncertain and inconſtant; when his jaws are too tight, and when he is ſtag-necked. If the SNAFFLE is uſed with the reins laſtened low, it becomes a *martingale*, or anſwers the purpoſe better; becauſe the hand can make it ſtrict or eaſy, or both by turns, as the rider pleaſes, and the horſe requires.

MARTINO *pescatore*, in *Ichthyology*, a name given by Salvian, and ſome others, to the RANA *piſcatrix* of authors; the *lophius* of Artedi.

St. MARTIN's *cope*. See COPE.

MARTIOBARBULI, among *the Romans*, a deſignation given to ſoldiers, who carried leaden balls to annoy the enemy with.

MARTIORA, or MARTICORA, in *Natural Hiſtory*, the name which the ancient Greeks gave to the animal which the Romans called MANTICHORA.

MARTLET, in *Heraldry*, a little bird repreſented without feet, and properly alſo without a beak.

It is uſed as a DIFFERENCE, or mark of diſtinction, of a younger brother; ſome ſay, more peculiarly of the fourth brother, or family. See HOUSE. See *Tab.* II. *Heraldry, fig.* 72.

MARTNETS, in *a ſhip*, ſmall lines laſtened to the leetch of a ſail, being reeved through a block on the top-maſt-head, and coming down by the maſt to the deck. Thoſe *martnets* which belong to the top-ſails are laſtened after the ſame way to the heads of the top-gallant-maſts, but their fall comes down no farther than the top, when it is haled. The word is, *cap the martnets*; i. e. haſe them up. Their deſign is, in furling the ſail, to bring that part of the leetch which is next the yard-arm cloſe to the yard, that ſo the ſail may furl up the cloſer.

MARTYNIA, in *Botany*, a genus of the *didynamia angioſpermia* claſs. Its characters are theſe: the flower, the empalement of which is cut into five parts, has one bell-ſhaped petal of the ringent kind, with a ſwelling tube, at the baſe of which is ſituated a gibbous nectarium; it has four ſlender incurved ſtamina, which are inflexed into each other, and an oblong germen ſituated under the flower; the empalement afterwards turns to an oblong gibbous capſule, which divides into two parts, including a hard nut ſhaped like the body of a ſtag beetle, with two incurved ſtrong horns at the end, having four cells, two of which are generally barren, the other two have an oblong ſeed in each. There are three ſpecies, natives of the ſouthern parts of North America.

MARTYR, a perſon who ſuffers torments, and even death, in defence of the truth of the goſpel.

The word is Greek, *μαρτυς*, and properly ſignifies *a witneſs*. It is applied by way of eminence, to thoſe who ſuffer in witneſs of the truth of the goſpel.

Anciently thoſe who were baniſhed for the faith, were called *martyrs*, and alſo thoſe who periſhed in the holy wars. In the time of St. Auguſtine, the title of *martyr* was given to confeſſors, or thoſe who were tortured for the faith, without loſing their lives. It is Tertullian's thought in his Apologetic: *Plures efficimur, quoties metimur; ſemen eccleſiæ eſt ſanguis Chriſtianus.*

St. Stephen is called the *proto-martyr*, or firſt *martyr*.—Nineteen thouſand ſeven hundred are computed to have ſuffered *martyrdom* with St. Irenæus at Lyons, under the empire of Severus: ſix thouſand ſix hundred and ſixty-ſix ſoldiers of the Theban legion are ſaid to have been *martyred* in Gaul: Father Papebroch reckons ſixteen thouſand Abyſſinian *martyrs*, and one hundred and fifty thouſand others under Dioclefian alone.

Mr. Dodwell endeavours to prove, in a diſſertation expreſs, that the number of *martyrs* who ſuffered under the Roman emperors, was very moderate; alledging, that thoſe we have accounts of in the fathers, come within a very ſmall compaſs; and that, excepting Nero and Domitian, the reſt of the emperors made ſcarce any. F. Ruinart, on the contrary, endeavours to prove, that the catalogue of *martyrs* is not at all ſwelled; that the carnage was immenſe under the firſt emperors, and eſpecially in the time of Dioclefian. F. Papebroch, in his *Acta ſanctorum*, alſo makes the number of *martyrs* immenſe. The truth lies probably between the extremes.

There is ſcarce any ſect or religion that does not pretend to its *martyrs*: Mahometans, heathens, idolaters, &c. all have their *martyrs*.

In the ancient church, the acts, ſayings, ſufferings, and deaths, of the *martyrs*, were preſerved with great care, in order to be read on certain days, and thus propoſed as models to future ages: and yet notwithſtanding all this diligence, we have but very little left of them: the greateſt part of them having been deſtroyed, during that dreadful perſecution, which Dioclefian carried on for ten years, with freſh fury, againſt the Chriſtians: for a moſt diligent ſearch was then made after all their books and papers; and all of them that were found were committed to the flames. Euſebius, indeed, compoſed a *martyrology*, but it never reached down to us; and thoſe ſince compiled are extremely ſuſpected.

From the eighth century downwards, ſeveral Greek and Latin writers endeavoured to make up the loſs, by compiling, with vaſt labour, accounts of the lives and actions of the ancient *martyrs*: but moſt of them have given us little elſe than a ſeries of fables, adorned with profuſion of rhetorical flowers, and ſtriking images, as the wiſer, even among the Romiſh doctors, frankly acknowledge. Nor are thoſe records, that paſs under the name of MARTYROLOGY, worthy of ſuperior credit, ſince they bear the moſt evident marks both of ignorance and falſhood.

MARTYRS, *æra of*, is an æra followed in Egypt and Abyſſinia, and which even the Mahometans, ſince their becoming maſters of Egypt, frequently obſerve. See EPOCHA.

The æra of *martyrs* is alſo called the æra of Dioclefian.

MARTYROLOGY, from *μαρτυς*, *witneſs*, and *λεγω*, *dico*, *I ſpeak*; or *λεγω*, *colligo*, *I gather*; a regiſter or catalogue of *martyrs*.

A *martyrology*, properly ſpeaking, ſhould contain no more than the name, place, and day of martyrdom of each ſaint; but the term is frequently extended to the hiſtories of martyrs. The cuſtom of collecting *martyrologies* is borrowed from the heathens, who inſerted the names of their heroes in their *faſti*, to preſerve to poſterity the memory and example of their noble actions. Baronius gives pope Clement the credit of being the firſt who introduced the cuſtom of collecting the acts of the martyrs.

The *martyrology* of Euſebius of Cæſarea was the moſt celebrated in the ancient church. It was tranſlated into Latin by St. Jerom; but the learned agree, that it is not now extant. That attributed to Beda, in the eighth century, is of very doubtful authority; the names of ſeveral ſaints being there found, who did not live till after the time of Beda. The ninth century was very fertile in *martyrologies*: then appeared that of Florus, ſubdeacon of the church at Lyons; who, however, only filled up the chaſms in Beda. This was publiſhed about the year 830, and was followed by that of Walden burtus, monk of the diocefe of Treves, written in verſe about the year 848, and this by that of Uſuard, a French monk, and written by the command of Charles the Bald, in 875, which laſt is the *martyrology* now ordinarily uſed in the Romiſh church. That of Rabanus Maurus is an improvement on Beda and Florus, written about the year 845; that of Notker, monk of St. Gal, was written about the year 894.

The *martyrology* of Ado, monk of Ferrieres, in the diocefe of Treves, afterwards archbiſhop of Vienne, is a deſcendant of the Roman, if we may ſo call it; for Du Solier gives its genealogy thus: the *martyrology* of St. Jerom is the great Roman *martyrology*; from this was made the little Roman one printed by Roſweyd; of this little Roman *martyrology* was formed that of Beda, augmented by Florus. Ado compiled his in the year 858.

The *martyrology* of Nevelon, monk of Corbie, written about the year 1089, is little more than an abridgment of that of Ado; father Kircher alſo makes mention of a Coptic *martyrology*, preferred by the Maronites at Rome.

We have alſo ſeveral proteſtant *martyrologies*, containing the ſufferings of the reformed under the papiſts; viz. an Engliſh *martyrology*, by J. Fox; with others, by Clark, Bray, &c.

MARTYROLOGY is alſo uſed, in the *Romiſh church*, for a roll or regiſter kept in the veſtry of each church, containing the names of all the ſaints and martyrs, both of the univerſal church, and of the particular ones of that city or monaſtery.

MARTYROLOGY, is alſo applied to the painted or written catalogues in the Romiſh churches, containing the foundations, obits, prayers, and maſſes, to be ſaid each day.

MARUZIAN, in the *Materia Medica*, a word formed by the modern Greek writers, to expreſs a ſort of ſea-plant, growing upon the rocks, and uſed in painting, dying, &c.

The word is formed of the Arabian name MARGIAN, by changing the *g* into *r*.

MARU, in *Botany*, a name by which Dodonæus, and ſome others, have called the *cerinthe*, or *honey-wort*.

MARUBIUM, in *Botany*, &c. See HORE-HOUND.

MARVEL *of Peru*, or *Four-o'Clock-Flower*, *mirabilis*, in *Botany*, a genus of the *pentandria monogynia* claſs. Its characters are, that the empalement of the flower has five oval, ſpear-ſhaped, ſmall leaves, membranaceous, ſwelling, and permanent; the flower has one funnel-ſhaped petal, with a long ſlender tube [illegible] the nectarium, which ſpreads open above, and is cut into five ob-

tuſe

tuse segments; it hath five slender stamina, which adhere to the petal, which are unequal and inclined, terminated by roundish summits, with a roundish germen within the nectarium, which becomes an oval five-cornered nut, inclosing one seed. There are three species. Tournefort was informed by father Plumier, that a species of this genus common in all the West Indian islands, where the inhabitants call it the *four o'clock* flower, from the flower's opening at that time of the day, was the officinal JALAP; but the late Dr. Houstoun was fully informed, in the Spanish West Indies, of the contrary, and brought over a drawing of the plant, which was made by a Spaniard at Halapa; and he carried two or three of the plants to Jamaica, where he planted them in a garden, but after he left the island they were destroyed by the hogs; however, he was fully satisfied of its being a CONVOLVULUS: but the roots of *marvel of Peru* are purgative, and when given in a double quantity for a dose will answer the purpose of JALAP.

There are two varieties of the first species of this beautiful plant propagated in flower-gardens, which are very ornamental during the months of July, August, and September. The flowers do not open till toward the evening, while the weather is warm; but in moderate cool weather, when the sun is obscured, they continue open almost the whole day. They are to be raised by sowing their seeds in March, on a moderate hot-bed. When they come up to the height of two inches, they are to be transplanted to another hot-bed; or if they are transplanted into pots filled with light earth, and plunged into a moderate hot-bed; while they are in the second hot-bed they should be shaded, till they have taken root; after which they must have plenty of fresh air; and in May they must be gradually inured to bear the open air; in the beginning of June they may be transplanted into the borders of the pleasure garden; and after they have taken new root they will require no farther care.

Some take up the roots when the stalks are dead, and lay them up in sand till spring, when they are planted again into pots, and plunged into a moderate hot-bed to facilitate their taking root. And the plants, from the roots of the former year, will always flower much stronger than the seedlings of the same year's growth. Miller.

MARUM, in *Botany*. See SAVORY, *Tree* GERMANDER, and *Herb* MASTICH.

MARY.—*Knights of St.* MARY, is a name by which several orders of knighthood are distinguished.—As, *St. Mary of the Thistle*. See THISTLE. *St. Mary of the Conception*. See CONCEPTION. *St. Mary of the Elephant*. See ELEPHANT. *St. Mary and Jesus*. *St. Mary of Loretto*. *St. Mary of Mount Carmel*. See CARMEL. *St. Mary of the Teutonics*. See TEUTONIC, &c.

MARYGOLD, *calendula*, in *Botany*, a genus of the *syngenesia polygamia necessaria* class. Its characters are these: it has a compound radiated flower, the borders or rays being composed of female florets, which are stretched out on one side like a tongue; the hermaphrodite flowers which compose the disk are tubulous and quinquefid; the germen is situated under the petal; these flowers are barren, but the female flowers are each succeeded by one oblong incurved seed, with angular membranes.

Miller enumerates ten, and Linnæus eight species of the common *marygold*: there are the following varieties, viz. the common single, the double flowering, the largest very double flower, the double lemon-coloured flower, and the greater and smaller childing *marygold*.

The flowers of the single *marygold* are said to be cordial and alexipharmic, to promote sweat, and to be good for throwing out the small-pox, or any other eruption.—They have been recommended also for promoting the menses, and have been deemed so far aperient, as to be of service in the jaundice, and in indurations of the spleen; but they appear from their sensible qualities to be of little activity. The midwives burn them under women whose labour does not come on properly, and suppose they are of great virtue in promoting the pains. They also distil a water from them, as a remedy for sore eyes: but these last virtues are not so well warranted as the former.

The leaves of the plant appear to be of greater virtue than the flowers: their expressed juice has been given, in doses of two or three ounces or more, as an aperient; and is said to loosen the belly, and promote the natural secretions in general. Lewis.

MARYGOLD, *African*. See *French* MARYGOLD.

MARYGOLD, *corn*, *chrysanthemum*, in *Botany*, a genus of the *syngenesia polygamia superflua* class. Its characters are these: it hath a compound flower, the rays composed of female florets, which are extended on one side like a tongue; these have an oval germen; the hermaphrodite flowers, which compose the disk, are funnel-shaped, divided into five parts at the top; these have five short hairy stamina, and an oval germen, which afterward becomes a single, oblong, naked seed. Linnæus enumerates twenty-two, and Miller only twelve species, native of various parts; one of them is the common *corn marygold*, which grows naturally in our corn fields.

MARYGOLD, *fig*, in *Botany*. See MESEMBRYANTHEMUM.

MARYGOLD, *French*, *tagetes*, in *Botany*, a genus of the *syngenesia polygamia superflua* class. Its characters are these: the common empalement of the flower is single, oblong, erect, and five-cornered; the flower is compound and radiated; the ray or border is composed of five female half florets, which are tongue-shaped; the disk or middle is made up of hermaphrodite florets, which are tubulous, cut into five obtuse segments; these have five short hair-like stamina, terminated by cylindrical summits and an oblong germen, supporting a slender style, crowned by a bifid, reflexed stigma; the germen afterwards becomes a single, linear, compressed seed, almost the length of the empalement, crowned by five acute, pointed, unequal scales; the female half-florets have an oblong germen, with a style and stigma like the hermaphrodite; and are succeeded by seeds of the same form, but have no stamina.

Miller enumerates four, and Linnæus three species, including several varieties, which are raised in our gardens, for the beauty of their flowers. They are propagated by sowing the seeds in spring, on a moderately hot-bed; when the young plants come up, they must have air allowed them; and when three inches high, they should be removed to another hot-bed, which should be arched over with hoops that it may be sheltered with mats. They are to be planted here at about six inches distance, and when they are grown stronger, as about the beginning of May, they are to be taken up with a ball of earth about their roots, and placed where they are to remain: or else at eighteen inches distance in a nursery, where, when they flower, the finest sorts may be marked and removed, with a large ball of earth to their roots, either into pots, or into the borders of the flower-garden. They are very beautiful; but their smell is very offensive. Miller.

MARYGOLD, *marsh*, *caltha*, in *Botany*, a genus of the *polyandria polygynia* class. Its characters are these: the flower hath no empalement, but is composed of five large oval petals, which are concave, and has a great number of slender stamina; in the centre are situated several oblong compressed germina, which afterward become so many short pointed capsules, containing many roundish seeds. Linnæus reckons only one species, which grows on boggy land, in many parts of England; but Miller mentions two.

MARYGOLD, *Zoophyte*, in *Natural History*, the name of a species of sea-animal, of a very beautiful kind, and of the nature of those commonly called *zoophytes*, or plant-animals, by the old naturalists. In St. Lucy's parish, in Barbadoes, there is a cave, in which is a basin of very clear salt water; and in the midst of this basin lies a stone, which has been for many years found to be the habitation of a great number of animals of this species. The stone is always covered with water; and from small holes in its sides, in several parts, there appear, at all times of the year, a number of creatures representing the flowers of some of the radiated plants, and particularly of the common *marygold*: they are yellow, and seem composed of a very great number of petals. These, in their natural state, are all regularly and beautifully expanded; but as soon as any thing disturbs them, if it be only the motion of a stick, that comes within three or four inches of them, they in an instant close all the leaves up together, and the whole body, flower, stalk and all, is retracted back into the hole of the stone; but if the water be left a few minutes undisturbed again, they will appear and expand themselves in the former manner.

When they are nicely observed, there is a yet farther resemblance of a flower in their structure; for there arise from the centre of the body certain oblong bodies, which very naturally resemble the stamina arising from the center of a flower; but these have evidently the powers of animal-limbs; for they no sooner appear, but they dart themselves about to the verge of the flower in several directions, and are plainly busied in search of prey.—They are composed of several joints, and the creature often makes them meet in the manner of a forceps, to lay hold of any thing it pleases. These parts, however, seldom appear thus extended any long time together, but are, after a time, received back into the body.

These arms may easily be conceived to be of use to draw in the prey within the compass of the body of the animal; and as soon as it is there, the same contraction of the several

ſeveral rays which ſerves them to eſcape danger, and bury themſelves in the cavity of the ſtone, will alſo ſerve to hold faſt the prey till the creature has fed on it. Beſide theſe large yellow radiated *zoophytes*, the top of the ſtone uſually affords a number of others of a blue colour, which ſtand among a ſort of veſicles of water-bladders, diſpoſed like cluſters of grapes. Philoſ. Tranſ. N° 470. p. 591.

MASARANDIBA PISON, in *Botany*, a tree which grows in Braſil, very like our European cherry-tree, in every reſpect, except that the fruit it produces is not ſo round as our cherries. This fruit contains a very hard ſtone, and a very agreeable milky juice; which is expreſſed by the inhabitants of Braſil, and taken by way of emulſion, as a remedy for cold affections of the breaſt, and hoarſeneſs, either alone or joined with other pectorals. James.

MASARINO, in *Ornithology*, a name given by the Portugueſe, in the Braſils, to a large bird of the curlew kind, approaching to the gooſe in ſize; and more commonly known by its Braſilian name CUBICACA.

MASBOTHÆI, or MESBOTHÆI, the name of a ſect, or rather of two ſects; for Euſebius, or rather Hegeſippus, whom he cites, makes mention of two different ſects of *Maſbotheans*. The firſt was one of the ſeven ſects that aroſe out of Judaiſm, and proved very troubleſome to the church: the other was one of the ſeven Jewiſh ſects before the coming of Jeſus Chriſt.

The word is derived from the Hebrew שבת, *ſchabat, to reſt, or repoſe*, and ſignifies idle, eaſy indolent people. Euſebius ſpeaks of them, as if they had been ſo called from one *Maſbotheus*, their chief: but it is much more probable, that their name is Hebrew, or at leaſt Chaldaic, ſignifying the ſame thing with a Sabbatarian in our language, that is, one who makes profeſſion of keeping ſabbath.

Valeſius will not allow the two ſects to be confounded together: the laſt being a ſect of Jews before, or at leaſt contemporary with Chriſt; and the former a ſect of heretics deſcended from them. Rufinus diſtinguiſhes them in their names: the Jewiſh ſect he calls *Maſbotheï*; and the heretics *Maſbotheani*. The *Maſbotheans* were a branch of the Simonians.

MASCHARADA, in the *Italian Muſic*, is applied to muſic compoſed for the geſtures of pantomimes, buffoons, mimics, and ſuch groteſque characters.

MASCLE, or MACLE, in *Heraldry*, a bearing in form of a lozenge, and voided of the field; that is, its inner part being cut out. See *Tab. Herald. fig.* 34.

He bears gules, a chevron ermin, between three *maſcles* argent, by the name of *Baltgrave*.

According to Guillim, the *maſcle* repreſents the maſh of a net and is an honourable bearing. It only differs from a lozenge, by being voided.

MASCULINE, ſomething belonging to the male, or the ſtronger of the two ſexes.

MASCULINE is more ordinarily uſed, in *Grammar*, to ſignify the firſt and worthieſt of the genders of nouns.

The *maſculine* gender is that which belongs to the male kind, or ſomething analogous to it.

Moſt ſubſtances are ranged under the heads of *maſculine* or feminine. This, in ſome caſes, is done with a ſhew of reaſon, but in others it is merely arbitrary; and, for that reaſon, is found to vary according to the languages, and even according to the words introduced from one language into another. Thus the names of trees are generally feminine in Latin, and *maſculine* in the French. Farther, the genders of the ſame word are ſometimes varied in the ſame language. Thus *abus*, according to Priſcian, was anciently *maſculine*, but is now become feminine. And *navire*, a ſhip, in French, was anciently feminine, but is now *maſculine*. See GENDER.

MASCULINE *rime*, in the *French Poetry*, is that made with a word which has a ſtrong, open, and accented pronunciation; as all words have, excepting thoſe which have an *e* feminine in their laſt ſyllable.

For inſtance, *amour* and *jour*, *mort* and *ſort*, are *maſculine* rimes; and *pere* and *mere*, *gloire* and *memoire*, are feminine. Hence alſo verſes ending with a *maſculine* rime, are called *maſculine* verſes; and thoſe ending with a feminine rime, feminine verſes.

It is now a rule eſtabliſhed among the French poets, never to uſe above two *maſculine*, or two feminine verſes ſucceſſively, except in the looſer kinds of poetry.

Marot was the firſt who introduced this mixture of *maſculine* and feminine verſes; and Ronſard was the firſt who practiſed it with ſucceſs. The *maſculine* verſes, in French, ſhould always have a ſyllable leſs than the feminine ones.

MASCULINE *Signs*.—Aſtrologers divide the ſigns, &c. into *maſculine* and feminine; by reaſon of their qualities, which are either active, and hot, or cold, accounted *maſculine*; or paſſive, dry, and moiſt, which are feminine. On this principle they call the Sun, Jupiter, Saturn, and Mars, *maſculine*; and the Moon and Venus, feminine. Mercury, they ſuppoſe, partakes of the two. Among the ſigns, Aries, Libra, Gemini, Leo, Sagittarius, and Aquarius, are ſaid to be *maſculine*; Cancer, Capricornus, Taurus, Virgo, Scorpio, and Piſces, are feminine.

MASH, the name of a drink given to horſes or cattle. It is made of half a peck of ground malt, put into a pail; on which is poured as much hot ſcalding water, as will wet it well; then ſtirring it about half an hour, till it becomes lukewarm, and ſweet like honey, it is to be given to the horſe.

A *maſh* is only given after a purge, to make it work better; after hard labour, or for drink in time of ſickneſs.

MASK, or MASQUE. See MASQUE.

MASLACH, the name of a medicine greatly in uſe among the Turks, and called alſo *amſun* or *amphion*. It is prepared principally of opium. They take a dram of it at a time, and ſometimes two or three: they always uſe it when going to battle, and very often as a provocative to venery, as they do the crude opium.

MASLIN. See BULLIMONY.

MASON, a perſon employed uſually under the direction of an architect, in the raiſing of a ſtone building.

The word comes from the French *maçon*, which ſignifies the ſame. Some derive this farther from the barbarous Latin *machio*, *a machiniſt*, in regard theſe artificers are obliged to uſe machines for raiſing walls. Du-Cange derives it from *macerie*, a name given to the long fence-walls which incloſe vineyards, &c. in which *maſons* are ſuppoſed to have been firſt employed: *Maſon eſt Macerarum conſtructor*. M. Huet derives it from *mas*, an old word, ſignifying *houſe*; hence *maſon* is a perſon who makes *maſſes*, that is, *houſes*. In the corrupt Latin, a *maſon* was called *magiſter comacinus*, which Lindenbroeck derives from Comacina, an iſland in Romanis, where, in the time of the Lombards, the beſt architects were found.

The chief buſineſs of a *maſon* is to prepare the mortar, raiſe the walls from the foundation to the top, with the neceſſary retreats and perpendiculars, form the vaults, and employ the ſtones as delivered to him.

When the ſtones are large, the buſineſs of hewing or cutting them belongs to the ſtone-cutters; though theſe are frequently confounded with the *maſons*. The ornaments of ſculpture are performed by carvers in ſtone, or ſculptors. The tools or implements principally uſed by *maſons* are, the ſquare, level, plumb-line, bevel, compaſs, hammer, chiſſel, mallet, ſaw, trowel, &c.

Beſides the common inſtruments uſed in the hand, they have likewiſe machines for the raiſing of great burdens, the conducting of large ſtones, &c. The principal of theſe are the lever, wheel, pulley, &c.

MASONS, *free or accepted*, a very ancient ſociety, or body of men, ſo called either from ſome extraordinary knowledge of maſonry or building, which they are ſuppoſed to be maſters of, or becauſe the firſt founders of the ſociety were perſons of that profeſſion.

They are now very conſiderable both for numbers and character; being found in every country in Europe, and conſiſting principally of perſons of merit and conſideration. As to antiquity, they lay claim to a ſtanding of ſome thouſand years; and, it is ſaid, can trace up their original as early as the building of Solomon's temple.—It is very doubtful when they were firſt introduced into this country: ſome have traced the origin of maſonry in general to the year 674, when GLASS-*making* was introduced: and it is certain that, after this time, many of our public buildings, in the Gothic ſtyle, were erected by men in companies, who, as ſome ſay, called themſelves *free*, becauſe they were at liberty to work in any part of the kingdom. Others have derived the inſtitution of *free maſons* from a combination among the *maſons* not to work without an advance of wages, when they were ſummoned from ſeveral counties, by writs of Edward III. directed to the ſheriffs, to aſſiſt in rebuilding and enlarging the caſtle, together with the church and chapel of St. George, at Windſor: accordingly it is ſaid, that the *maſons* agreed on tokens, &c. by which they might know one another, and to aſſiſt one another againſt being impreſſed, and not to work unleſs *free*, and on their own terms.

What the end of their inſtitution is, ſeems ſtill, in ſome meaſure, a ſecret; though ſo much of it as is known appears laudable enough, as it tends to promote friendſhip, ſociety, mutual aſſiſtance, and good fellowſhip.

The brothers of this family are ſaid to be poſſeſſed of a great number of ſecrets, which have been religiouſly obſerved from age to age.

MASONRY, a branch of architecture, conſiſting in the art of hewing or ſquaring ſtones, and cutting them level and perpendicular, for the uſes of building.

MASONRY, in a more limited ſenſe of the word, is the art of aſſembling and joining ſtones together with mortar. Hence there ariſe as many different kinds of *maſonry* as there are different forms and manners of laying or joining the ſtones. Vitruvius makes mention of ſeven kinds of *maſonry*, uſed among the ancients; three of hewed ſtone, viz. that in form of a *net*, that in *binding*, and that called the *Greek maſonry*: and three of unhewed ſtones, viz. that of an *equal courſe*, that of an *unequal courſe*, and that *filled up in the middle*. The ſeventh was a compoſition of all the reſt. See *Tab. Archit. fig.* 13. *to* 18.

MASONRY, *net*, called by Vitruvius, *reticulatum*, from its reſemblance of the meſhes of a *net*, conſiſts of ſtones ſquared in their courſes, and ſo diſpoſed, as that their joints go obliquely, and the diagonals are, the one perpendicular, and the other level. This is the moſt agreeable *maſonry* to the eye; but it is very apt to crack. See *fig.* 13.

MASONRY, *bound*, *inſerta*, is that wherein the ſtones were placed one over another, like tiles; the joints of the beds being level, and the mounters perpendicular. So that the joint that mounts and ſeparates two ſtones, always falls directly over the middle of the ſtone below. This is leſs beautiful than the net-work; but is more ſolid and durable. See *fig.* 16.

MASONRY, *Greek*, according to Vitruvius, is that where, after we have laid two ſtones, each of which makes a courſe, another is laid at the end, which makes two courſes; and the ſame order is obſerved throughout the building. This may be called *double binding*, in regard the binding is not only of ſtones of the ſame courſe with one another, but likewiſe of one courſe with another courſe. See *fig.* 14.

MASONRY *by equal courſes*, by the ancients called *iſodomum*, differs in nothing from the bound *maſonry*, but only in this, that its ſtones are not hewn.

MASONRY *by unequal courſes*, called *pſeudiſodomum*, is alſo made of unhewed ſtones, and laid in bound work: but then they are not of the ſame thickneſs, nor is there any equality obſerved, excepting in the ſeveral courſes; the courſes themſelves being unequal to each other. See *fig.* 15.

MASONRY *filled up in the middle*, called by the ancients *emplecton*, is likewiſe made of unhewed ſtone, and by courſes; but the ſtones are only ſet in order as to the courſes, the middle being filled up with ſtones thrown in at random among the mortar. See *fig.* 17.

MASONRY, *compound*, is of Vitruvius's propoſing; ſo called, as being formed of all the reſt. In this, the courſes are of hewed ſtone: and the middle, being left void, is filled up with mortar and pebbles thrown in together. After this, the ſtones of one courſe are bound to thoſe of another courſe, with cramp-irons faſtened with melted lead. See *fig.* 18.

All the kinds of *maſonry* now in uſe may be reduced to theſe five; viz. *bound maſonry*; that of *brick work*, where the bodies and projectures of the ſtones incloſe ſquare ſpaces or panels, &c. ſet with brick; that *de moilon* or of ſmall work, where the courſes are equal, well ſquared, and their edges or beds ruſticated; and that where the *courſes* are *unequal*; and that *filled up in the middle* with little ſtones and mortar.

MASONRY is ſometimes alſo uſed in a more general and unlimited ſenſe; ſo as, beſides proper *maſonry*, to include the hewing or ſawing of larger ſtones to fit them for building, properly called *ſtone-cutting*; and the carving of the ornaments on the members and mouldings, properly called *ſculpture*.

MASORA, a term in the *Jewiſh Theology*, ſignifying a work on the Bible, performed by ſeveral learned rabbins, to ſecure it from any alterations which might otherwiſe happen.

Their work regards merely the letter of the Hebrew text; in which they have, firſt, fixed the true reading by vowels and accents: they have, ſecondly, numbered not only the chapters and ſections, but the verſes, words, and letters of the text: and they find in the Pentateuch 5245 verſes, and in the whole Bible 23206. The *maſora* is called, by the Jews, the hedge or fence of the law, becauſe this enumeration of the verſes, &c. is a means of preſerving it from being corrupted and altered. They have, thirdly, marked whatever irregularities occur in any of the letters of the Hebrew text; ſuch as the different ſize of the letters, their various poſitions and inverſions, &c. and they have been fruitful in finding out reaſons for theſe irregularities and myſteries in them. See CABBALISTS. They are, fourthly, ſuppoſed to be the authors of the Keri and Cherib, or the marginal corrections of the text in our Hebrew Bibles.

The text of the ſacred books, it is to be obſerved, was originally written without any breaks, or diviſions into chapters or verſes, or even into words; ſo that a whole book, in the ancient manner, was but one continued word: of this kind we have ſtill ſeveral ancient manuſcripts, both Greek and Latin. In regard, therefore, the ſacred writings had undergone an infinite number of alterations, whence various readings had ariſen, and the original was become much mangled and diſguiſed, the Jews had recourſe to a canon, which they judged infallible, to fix and aſcertain the reading of the Hebrew text; and this rule they call *maſora*, *tradition*, from מָסַר *tradidit*, as if this critique were nothing but a tradition which they had received from their forefathers. Accordingly they ſay, that when God gave the law to Moſes, at Mount Sinai, he taught him, firſt, the true reading of it, and, ſecondly, its true interpretation; and that both theſe were handed down by oral tradition, from generation to generation, till at length they were committed to writing. The former of theſe, viz. the true reading, is the ſubject of the *maſora*; the latter, or true interpretation, that of the MISHNA and GEMARA.

According to Elias Levita, they were the Jews of a famous ſchool at Tiberias, about 500 years after Chriſt, who compoſed, or at leaſt began the *maſora*; whence they are called *maſorites*, and *maſoretic doctors*. Aben Ezra makes them the authors of the points and accents in the Hebrew text, as we now find it; and which ſerve for vowels. See POINTS.

The age of the *maſorites* has been much diſputed. Archbiſhop Uſſher places them before Jerom; Capel at the end of the fifth century; father Morin in the tenth century: Baſnage ſays, that they were not a ſociety, but a ſucceſſion of men; and that the *maſora* is the work of many grammarians, who, without aſſociating and communicating their notions, compoſed this collection of criticiſms on the Hebrew text. It is urged that there were *maſorites* from the time of Ezra and the men of the great ſynagogue, to about the year of Chriſt 1030; and that Ben Aſher and Ben Naphtali, who were the beſt of the profeſſion, and who, according to Baſnage, were the inventors of the *maſora*, flouriſhed at this time.—Each of theſe publiſhed a copy of the whole Hebrew text, as correct, ſays Dr. Prideaux, as they could make it. The eaſtern Jews have followed that of Ben Naphtali, and the weſtern that of Ben Aſher; and all that has been done ſince is to copy after them, without making any more corrections, or *maſoretical* criticiſms.

The Arabs have done the ſame thing by their Koran, that the *maſorites* have done by the Bible: nor do the Jews deny their having borrowed this expedient from the Arabs, who firſt put it in practice in the ſeventh century.

There is a *great* and a *little maſora*, printed at Venice, and at Baſil, with the Hebrew text, in a different character. Buxtorf has written a *maſoretic* commentary, which he calls *Tiberias*. See on this ſubject Jennings's Jewiſh Ant. vol. i. p. 400, &c. and the various authors there cited.

MASORITES, Jewiſh doctors, authors of the MASORA.

MASQUE, or MASK, a cover for the face, contrived with apertures for the eyes and mouth; originally worn chiefly by women of condition, either to preſerve their complexion from the weather, or out of modeſty, to prevent their being known.

Poppæa, wife of Nero, is ſaid to be the firſt inventor of the *maſque*; which ſhe did to guard her complexion from the ſun and weather, as being the moſt delicate woman, with regard to her perſon, that has been known.

Theatrical *maſques* were in common uſe both among the Greeks and Romans: Suidas and Athæneus aſcribe the invention of them to the poet Choerilus, a contemporary of Theſpis; Horace attributes them to Æſchylus; but Ariſtotle informs us, that the real inventor, and, conſequently, the time of their firſt introduction and uſe, were unknown. Brantome obſerves, that the common uſe of modern *maſques* was not introduced till towards the end of the ſixteenth century.

MASQUE is alſo uſed to ſignify any thing uſed to cover the face, and prevent a perſon's being known.

The penitents of Lyons and Avignon hide their faces with large white veils, which ſerve them for *maſques*.

MASQUE, in *Architecture*, is applied to certain pieces of ſculpture, repreſenting ſome hideous forms, groteſque, or letyrs faces, &c. uſed to fill up and adorn vacant places, as in friezes, the panels of doors, keys of arches, &c. but particularly in grottos.

MASQUERADE, or MASCARADE, an aſſembly of perſons maſqued or diſguiſed, meeting to dance and divert themſelves. This was much in uſe with us, and has been long a very common practice abroad, eſpecially in carnival time.

The word comes from the Italian *mascarata*, and that from the Arabic *maskara*, which signifies *raillery, buffoonery*. Granacci, who died in 1543, is said to have been the firſt inventor of *maſquerades*. Encyclopedie.

MASRAKITHA, a pneumatic inſtrument of muſic among the ancient Hebrews, compoſed of pipes of various ſizes, fitted into a kind of wooden cheſt, open at the top, and ſtopped at the bottom with wood covered with a ſkin. Wind was conveyed to it from the lips, by means of a pipe fixed to the cheſt: the pipes were of lengths muſically proportioned to each other, and the melody was varied at pleaſure, by ſtopping and unſtopping with the fingers the apertures, at the upper extremity. See Kircher's figure in *Tab. Muſic. fig.* 10.

MASS, MASSA, in *Mechanics*, the matter of any body cohering with it; i. e. moving and gravitating along with it. In this ſenſe, *maſs* is diſtinguiſhed from bulk, or volume, which is the expanſion of a body in length, breadth, and thickneſs.

The *maſs* of any body is rightly eſtimated by its weight. And the *maſſes* of two bodies of the ſame weight are in a reciprocal ratio of their bulks. See MATTER.

MASS, or MESS, *miſſa*, in a religious ſenſe, denotes the office, or public prayers made in the Romiſh church, at the celebration of the euchariſt.

Nicod, after Baronius, obſerves, that the word comes from the Hebrew, *miſſach, oblatum*; or from the Latin, *miſſa, miſſorum*; becauſe, in former times, the catechumens and excommunicated were ſent out of the church, when the deacon ſaid, *Ite, miſſa eſt*, after ſermon, and the reading of the epiſle and goſpel; they not being allowed to aſſiſt at the conſecration. Menage derives the word from *miſſo, diſmiſſing*: others from *miſſa, miſſan, ſending*; becauſe, in the *maſs*, the prayers of men on earth are ſent up to heaven.

Romiſh divines define the *maſs*, an oblation made to God, wherein, by the change of a ſenſible object by virtue of a divine inſtitution, the ſovereign dominion of God over all things is acknowledged.

This they eſteem the greateſt and moſt auguſt ceremony in uſe in the church; as being the ſacrifice of the new law, wherein the body and blood of Jeſus Chriſt are offered up to God.

They are divided about the queſtion, whether or no it be proper or allowable for the ſame perſon to celebrate *maſs* ſeveral times in one day? having the authority of pope Leo, in his letter to Dioſcorus, for the affirmative ſide of the queſtion, and that of ſeveral of the councils for the negative.

There is a great variety of *maſſes* in the Romiſh church; the thing acquiring new titles, and appellations, according to the different rites, intentions, and manners, in which it is performed, as well as other circumſtances. Thus they have a

MASS, *Ambroſian*, celebrated according to the rite of St. *Ambroſe*; particularly uſed in Milan. See AMBROSIAN.

MASS, *Engliſh*, was the form which anciently obtained in *England*.

MASS, *Galliean*, is the rite that formerly obtained in the churches of *France*.

MASS, *Greek*, is that rehearſed according to the *Greek* rites, in the *Greek* language, and by *Greek* prieſts.

MASS, *Latin*, is that uſed in the *Latin* church, in the *Latin* tongue, and according to the rites of the *Latin* church.

MASS, *Mozarabic* or *Gothic*, is that which was formerly celebrated in Spain, the rites of which are ſtill practiſed in the churches of Toledo and Salamanca.

MASS, *high*, called alſo *grand* MASS, is that ſung by the choriſters, and celebrated with the aſſiſtance of a deacon and ſubdeacon.

MASS, *low*, is that wherein the prayers are all barely rehearſed, without any ſinging, and performed without much ceremony, or the aſſiſtance of any deacon or ſubdeacon.

MASS *of the Beata*, or *our Lady*, is that offered to God, by the means, and through the interceſſion, of the *Virgin*.

MASS, *low*, is a *maſs* rehearſed every day, at which the ladies and *bonne-mouche* of the place attend. This is alſo called the *perfumed maſs*.

MASS, *common*, or MASS *of the community*, in a monaſtery, is that celebrated at certain hours, whereat the whole body aſſiſts.

MASSES, *ſolitary* or *private*, were thoſe that were celebrated by the prieſt alone, in behalf of the ſouls detained in purgatory, as well as upon ſome other particular occaſions. Theſe *maſſes* were prohibited by the laws of the church in the eighth century, but they were a rich ſource of profit to the clergy. They were condemned by the canons of a ſynod, aſſembled at Mentz, under Charlemagne, as criminal innovations, and as the fruits of avarice and ſloth.

MASS *of the Holy Ghoſt*, is that celebrated at the beginning of any ſolemnity, or church aſſembly, commencing with an invocation of the *Holy Ghoſt*.

MASS, *holiday*, is that wherein certain prayers, or leſſons, are read, ſuitable to the day.

MASS *of indemnity*, was that wherein a perſon cleared himſelf of any calumny, by ſome proof agreed upon.

MASS *for the death of our enemies*, was a form that obtained a long time in Spain; but it was at length aboliſhed, as inconſiſtent with Chriſtian charity.

MASS *of the dead*, or *requiem*, is that performed at the requeſt of the deceaſed: the introit whereof begins with *Requiem*. In the thirteenth century it was the cuſtom, before criminals were carried out to execution, to make them attend at a *maſs of the dead*, rehearſed for the repoſe of their ſouls.

MASS, *pariſh*, or *great* MASS, is that which the perſon is obliged to rehearſe to his pariſhioners on Sundays and holidays.

MASS, *little*, is that ſaid at private altars with leſs ceremony.

The firſt *maſs* is that ſaid at break of day.

MASS *of a ſaint*, is that wherein God is invoked by the interceſſion of ſome ſaint.

Thus there are alſo *maſſes* of apoſtles, martyrs, pontiffs, virgins, &c.

MASS *of ſcrutiny*, was formerly rehearſed at the examination of catechumens, when inquiry was made as to their diſpoſition for baptiſm.

MASS, *ſilent*. See MISSA *baſſa*.

MASS, *dry*, is that where there is no conſecration; as that, according to Durandus, where the prieſt cannot conſecrate, by reaſon of his having ſaid *maſs* before on the ſame day: or it is that uſed by the candidates of the prieſthood, in order to their becoming acquainted with the ceremonies; as Eckius will have it.

MASS, *votive*, is an extraordinary *maſs*, beſides that of the day, rehearſed on ſome extraordinary occaſion.

MASS *of the preſanctified* is that in which there is no conſecration of the elements; but after ſinging ſome hymns, the bread and wine which were before conſecrated are received. This *maſs* is performed among the Greeks, who conſecrate the euchariſt in Lent only on Saturdays and Sundays. Among the Latins, it is uſed only on Good Friday.

MASS-*books, importing or filling of*, and other popiſh books, incurs a penalty of 40*l.* by 3 Jac. I. cap. 5. ſec. 25.

MASS, *Candle*. See CANDLE-*maſs*.

MASS, *Childer*. See CHILDER-*maſs*.

MASS, *Chriſt*. See CHRIST-*maſs*.

MASS *of pope Julius is a* very celebrated picture of Raphael, repreſenting the ceremony of the *maſs*, in the Vatican, and diſtinguiſhed by its rich and excellent colouring.

MASSES, in *Painting*, denote thoſe parts of a picture which contain great lights, or great ſhadows. See CLAIR-OBSCURE.

When it is almoſt dark, we only ſee the *maſſes* of a picture; i. e. the places of the greateſt lights and ſhadows.

MASSALIANS, MASSALIANI, certain ſectaries, ſo called from a Hebrew word ſignifying *prayer*; it being their diſtinguiſhing tenet, that a man is to be continually in prayer.

St. Epiphanius diſtinguiſhes two kinds of *Maſſalians*, the *ancient* and the *later*.

The *ancient*, according to him, were neither Jews, Chriſtians, nor Samaritans, but pure Gentiles; who, owning ſeveral gods, adored only one, whom they called Almighty.

For the *later Maſſalians*, who were by profeſſion Chriſtians, their riſe was not till about the time of St. Epiphanius. Their doctrine was, that prayer alone was ſufficient to ſalvation. Many monks, who loved a life of lazineſs, and were averſe from labour, at times, joined theſe *Maſſalians*. See EUCHITES.

MASSETER, in *Anatomy*, a triangular two-headed muſcle, which ſurrounds the lower jaw, and helps to pull it upwards in eating. See MAXILLA.

The *maſſeter* is thick and ſhort, ariſing from the zygoma, and from the firſt bone of the upper jaw, and is inſerted into the lower edge of the lower jaw, from its external angle to its middle. Its fibres run in three directions; thoſe from the zygoma obliquely to the middle of the jaw, and thoſe from the upper bone of the firſt jaw croſs the former, and run to the angle of the lower jaw; and the fibres that are in its middle run perpendicularly from their origin to their inſertion. See *Tab. Anat. (Myol.) fig.* 1. *n.* 11. *fig.* 6. *n.* 6. *fig.* 7. *n.* 3.

MASSICOT. See MASTICOT.

MASSIMA, in the *Italian Muſic*, is a note or character made in a long ſquare, with a tail to it; thus, . It contains eight ſemi-breves in common time. This character is diſuſed in the modern muſic, for they have found other ways to ſeparate the bars, and to mark the length of notes.

MASSIVE, ſomething heavy and ſolid; a term uſed in oppoſition to tenderneſs and delicacy.

Thus we ſay, a building is too *maſſive*, that is, its walls are too thick; a wall is *maſſive*, that is, the lights and openings are too ſmall in proportion.

MASSIVE *column*. See COLUMN.

MAST *of a foreſt*, the fruit of that *genus* of trees called *glandiferous*, or *maſt-bearing*; as beech, oak, cheſnut, &c.

MAST, in *Navigation*, a large pole, or long piece of round timber, raiſed in veſſels, to which are attached the yards, ſails, and rigging, in order to their receiving the wind neceſſary for navigation.

The word *maſt* ſignifies the ſame thing in French, High-Dutch, Flemiſh, and Engliſh; the Italians uſe the word *albero*, and the Spaniards *maſtil*.

In large veſſels the number of *maſts* is four: their names are the *main-maſt*, the *fore-maſt*, the *mizen-maſt*, and the *bow-ſprit*. To which ſome add a fifth; viz. a *counter-mizen*.

Main-maſt is the chief *maſt*, ſtanding upright in the middle, or waiſt of the veſſel; it bears the main-yard, and main-ſail.

Fore-maſt is between the *main-maſt* and the head.

Mizen-maſt is between the *main-maſt* and the ſtern.

The *bow-ſprit* lies under the beak, in the prow, or head, of the ſhip.

The *counter-mizen*, in large veſſels, and galleons, is in the ſtern. See *Tab. Ship, fig. 1. n. 1.* 19. 38. 81.

When a *maſt*, with regard to its length, is formed of one ſingle piece, it is called a *pole-maſt*: and we alſo uſe the word *maſt* to ſignify thoſe diviſions, or additional pieces, in the *maſts*, placed over one another. The *main-maſt* and *fore-maſt* have each of them two; viz. the *main-maſt*, *main-top-maſt*, *main-top-gallant-maſt*; the *fore-maſt*, *fore-top-maſt*, *fore-top-gallant-maſt*: and the *mizen-maſt* has one; viz. the *mizen-top-maſt*.

The lower *maſts* of the largeſt ſhips are compoſed of ſeveral pieces united into one body: as theſe are generally the moſt ſubſtantial parts of various trees, a *maſt*, formed by this aſſemblage, is juſtly eſteemed much ſtronger than one conſiſting of any ſingle trunk, whoſe internal ſolidity may be very uncertain. The whole is ſecured by ſeveral ſtrong hoops of iron, driven on the outſide of the *maſt*, where they remain at proper diſtances.

For the proportion of *maſts* Sir H. Manwaring gives theſe rules: whatever the breadth of a ſhip be in feet, multiply it by 3, the product is the length of her *main-maſt* in feet: thus if a ſhip be 30 feet at the midſhip beam, 3 of 30 is 24; therefore that ſhip's *main-maſt* muſt be 24 yards, or 72 feet in length. Then for its bigneſs he allows an inch to every yard in length, and therefore this *maſt* muſt be 24 inches through, or thick. The *fore-maſt* of a ſhip muſt be $\frac{3}{4}$ of the length of the *main-maſt*, that is, in this caſe, 19 yards, and thick, or through, it muſt be near 20 inches. The BOWYRIT is always of the ſame length and bigneſs with the *fore maſt*; and the *mizen-maſt* muſt be juſt half the length of the *main-maſt*, and half as thick.

Mr. Mungo Murray has given us the following table of the proportions for *maſts* in the royal navy, for the year 1745:

		Guns.
1000 : breadth in feet : : 748 : 756 : 753 : 741 : 740 : 747 : 760 :	main-maſt in yards	100 90 80 70 and 60 50 44 24
1000 : main-maſt : : 895 : 901 :	fore-maſt	100 90 80 all the reſt
1000 : main-maſt : : 870 : 866 :	mizen-maſt	100 90 80 all the reſt
1000 : main-maſt : : 640 : 613 :	bow-ſprit	100 90 80 all the reſt
1000 : main-maſt : : 600 : 605 : 607 :	main-top-maſt	100 90 80 70 60 50 40 24
1000 : main-top-maſt : : 900 : 910 :	fore-top-maſt	100 90 80 all the reſt
1000 : main-top-maſt : : 710 : 717 :	mizen-top-maſt	100 90 80 all the reſt
1000 : main-top-maſt : : 480 : 508 :	main-top-gallant-maſt	100 90 80 all the reſt
1000 : fore-top-maſt : : 480 : 505 :	fore-top-gallant-maſt	100 90 80 all the reſt
1000 : bow-ſprit : : 360 :	ſprit-ſail-top-maſt	100 90 80

The uſe of this table is eaſily underſtood; e. g. for the main-*maſt* of a ſhip of 50 guns, 1000 : 740 :: breadth : length, i. e. ſuppoſing the breadth 41 feet, 1000 : 740 :: 41 to a fourth, which will be the length of the *maſt*: or, by the SLIDING-*rule*, draw out the ſlider till 1000 is right againſt 740, and right againſt 41, you will find 30; nearly, which is the length of the main-*maſt* in yards, &c.

The proportions for the diameters are as follow:

For the main and fore-*maſt* in all ſhips down to 60 guns, one inch diameter to every yard in length.

For 50 and 40 guns, twenty-ſeven twenty-eighths of an inch diameter, to one yard in length.

For 24 guns, twelve-thirteenths of an inch diameter to one yard in length.

All top-*maſts* are nine-tenths of an inch diameter to one yard in length.

The fore-top-*maſt* as big as the main-top-*maſt*.

The top-gallant-*maſt*, one inch to a yard.

The mizen-*maſt* $\frac{1}{4}$ of an inch to one yard in length.

The mizen-top-*maſt* five-ſixths of an inch to one yard in length.

The bow-ſprit an inch and half to one yard.

The dimenſions of *maſts* for Eaſt India ſhips are:

	Length. *Feet.*	*Diameter.* *Inches.*
MAIN-MAST	80	24½
Top-maſt	50	15
Top-gallant-maſt	28	8
FORE-MAST	72	24
Top-maſt	48	15
Top-gallant-maſt	25	7½
MIZEN-MAST	70	17
Top-maſt	36	10
Bowſprit	50	25

M. Bouguer has given us the general proportions for the length and diameter of *maſts* uſed in France, with remarks, in his Traité du Navire. For an abſtract, ſee Supplement to Murray's Treatiſe on Ship-building, p. 23, &c.

MAST, *heel of a*. See HEEL.

MAST, *jury*. See JURY.

MAST, *armed*, in a ſhip, one that is made of more than one tree.

MAST, *ſpending a*, at ſea, is when it is broke by foul weather.

MAST, *ſpringing a*, at ſea, is when it is cracked in any place.

MASTED. A ſhip is ſaid to be *maſted*, when ſhe has all her maſts complete.

MASTED, *over*, or *four*-MASTED, is ſaid of a ſhip whoſe maſts are either too long or too big; which makes her lie too much down by the wind, and labour too much *a-hull*.

MASTED, *under*, or *low*-MASTED *ſhips*, ſuch whoſe *maſts* are either too ſmall, or too ſhort: in which caſe the cannot bear ſo great a ſail as ſhould give her true way.

MASTER, a title given to ſeveral officers and perſons of authority and command; particularly to the chiefs of the orders of knighthood, &c.

Thus we ſay, the grand-*maſter* of Malta; of St. Lazarus; of the Golden Fleece; of the Free Maſons, &c.

MASTER, *magiſter*, was a title frequent among the Romans: they had their *maſter* of the people, *magiſter populi*, who was the dictator. *Maſter* of the cavalry, *magiſter equitum*, who held the ſecond poſt in an army, after the dictator. Under the later emperors there were alſo *maſters* of the infantry, *magiſtri peditum*. A *maſter* of the conſuls,

magiſter

magister census, who had nothing of the charge of a censor, or subcensor, as the name seems to intimate; but was the same with the *præpositus frumentariorum*.

MASTER *of the militia*, *magister militiæ*, was an officer in the lower empire, created, as it is said, by Diocletian, who had the inspection and government of all the forces, with power to punish, &c. somewhat like a constable of France.

At first there were two of these officers instituted, the one for the infantry, and the other for the cavalry; but the two were united into one under Constantine. Afterwards, as their power was increased, so was their number also; and there was one appointed for the court, another for Thrace, another for the East, and another for Illyria. They were afterwards called *comites*, *counts*, and *clarissimi*. Their power was only a branch of that of the *præfectus prætorii*, who by that means became a civil officer.

MASTER *of arms*, *magister armorum*, was an officer, or comptroller, under the *master* of the militia.

MASTER *of the offices*, *magister officiorum*, had the superintendance of all the officers of the court: he was also called *magister officii palatini*; simply *magister*; and his post *magisterio*.

This officer was the same in the western empire, with the curopalates in the eastern.

MASTER, in the Roman history and laws, is used for every officer who is the chief of his kind; and has others of the same species, or that have the same functions, under him. In Latin, *magister*, and oftentimes *proximus*, or PRIMICERIUS.

MASTER *of the armory* is an officer who has the care and oversight of his majesty's ARMS and ARMORY.

MASTER *at arms*, is an officer appointed to teach the officers and crew of a ship of war, the exercise of small arms; to confine and plant centinels over the prisoners, and superintend whatever relates to them during their confinement. He is also to observe that the fire and lights are all extinguished as soon as the evening-gun is fired, except those which are permitted by proper authority, or under the inspection of centinels. It is likewise his duty to attend the gangway, when any boats arrive aboard, and search them carefully, together with their rowers, that no spirituous liquors may be conveyed into the ship, unless by permission of the commanding officer. In these several duties he is assisted by proper attendants, called his corporals, who also relieve the centinels and one another, at certain periods. Falconer.

MASTER of *arts*, the first DEGREE taken up in foreign universities, but the second in our's; candidates not being admitted to it till they have studied in the university seven years.

MASTER-*attendant*, is an officer in the royal dock-yards, appointed to hasten, and assist at, the fitting out or dismantling, removing, or securing vessels of war, &c. at the port where he resides. He is particularly to observe, that his majesty's ships are securely moored, and for this purpose he is expected frequently to review the moorings, which are sunk in the harbour, and observe that they are kept in proper repair. It is also his duty to visit all the ships in ordinary, and see that they are frequently cleaned and kept in order; and to attend at the general musters in the dock-yards, taking care that all the officers, artificers, and labourers, registered at the navy-books, are present at their duty. Falconer.

MASTER *of the ceremonies*, is an officer instituted by king James I. for the more solemn and honourable reception of ambassadors, and strangers of quality, whom he introduces into the presence.

The badge of this office is a gold chain and medal, having on one side an emblem of peace, with king James's motto; and on the reverse the emblem of war, with *Dieu, & mon droit*. He is always supposed to be a person of good address, and a master of languages, and has an appointment of 300*l.* a year: he is constantly attending at court, and hath under him an assistant *master*, or deputy, at 6*s.* 8*d.* a day, who holds his place during the king's pleasure.

There is also a third officer, called *marshal of the ceremonies*, with 10*l.* a year, whose business is to receive and distribute the *master*'s orders, or the deputy's, for the service; but, without their order, he can do nothing. This is in the king's gift.

MASTERS *of chancery* are usually chosen out of the barristers of the common law, and sit in chancery, or at the rolls, as assistants to the lord chancellor, and master of the rolls. All these, so late as the reign of queen Elizabeth, were commonly doctors of the civil law.

To them are also committed interlocutory reports, examination of bills in chancery, stating of accounts, taking casts, &c. and sometimes, by way of reference, they are impowered to make a final determination of causes.

They have, time out of mind, had the honour to sit in the lords house, though they have neither writs, nor patent, to impower them; but they are received as assistants to the lord chancellor, and master of the rolls. They had anciently the care of inspecting all writs of summons, which is now performed by the clerk of the petty-bag. When any message is sent from the lords to the commons, it is carried by the *masters of chancery*. Before them also affidavits are made, and deeds and recognizances acknowledged.

Besides these, who may be called *masters of chancery ordinary* (being twelve in number, whereof the *master* of the rolls is reputed the chief), there are also *masters of chancery extraordinary*, appointed to act in the several counties of England, beyond ten miles distance from London, by taking affidavits, recognizances, &c. for the ease of the suitors of the court.

MASTER *of the faculties*, an officer under the archbishop of Canterbury, who grants licences and dispensations: he is mentioned in the statute 22 and 23 Car. II. See COURT *of Faculties*.

MASTER-*gunner* of England. See GUNNER.

MASTER *of the horse*, a great officer of the crown, to whom is committed the charge of ordering and disposing all matters relating to the king's stables, races, and breed of horses, with a salary of 1266*l.* 13*s.* 4*d.* a year.

He hath a power of commanding the EQUERRIES, and all the other officers and tradesmen employed in the king's stables; to all which he gives, by his warrant to the avenor, the oath of allegiance, &c. for the faithful discharge of their duty. He has the peculiar privilege of making use of any horses, pages, or footmen, belonging to the king's stables; so that his coaches, horses, and attendants, are the king's, and have the king's arms and liveries.

There is also a *master* of the horse in the establishment of her majesty's household, with a salary of 800*l.* a year.

MASTER *of the household* is an officer under the lord steward of the household, in the king's gift; his business is to survey the accounts of the household.

Anciently the lord steward himself was called *grand-master of the household*.

MASTER *of the jewel-office*, is an officer of the king's household, who has charge of all the gold and silver plate used at the king's table, or at that of any officer attending the court, and of all plate remaining in the Tower of London; as also of chains, and loose jewels, not fixed to any garment. See JEWEL-*Office*.

MASTER *of the mint*, was anciently the title of him who is now called WARDEN *of the mint*; whose office is to receive the silver and bullion which comes to the mint to be coined, and to take care thereof.

The office of *master* and worker is now distinct: and this officer is allowed for himself and three clerks, 650*l.* a year.

MASTER *of the ordnance*. See ORDNANCE.

MASTER *of the revels*, an officer with an appointment of 100*l.* a year, whose business is to order all things relating to the performance of plays, masques, balls, &c. at court. Formerly he had also a jurisdiction of granting licences to all who travel to act plays, puppet-shews, or the like diversions; neither could any new play be acted at either of the two houses, till it had passed his perusal and licence; but these powers were afterwards much abridged, not to say annihilated, by a statute for regulating playhouses, till the licensing plays by the lord chamberlain was established. This officer has a yeoman, with 46*l.* 11*s.* 8*d.* per ann.

MASTER *of the rolls*. See ROLLS.

MASTER *of the rolls*, a patent-officer for life; who has the custody of the rolls and patents which pass the great seal; and of the records of the chancery.

In the absence of the lord chancellor, or keeper, he also sits as judge in the court of chancery; and is, by Sir Edward Coke, called his *assistant*.

At other times he hears causes in the rolls-chapel, and makes orders and decrees. He is also the first of the masters of chancery, and hath their assistance at the rolls: but all hearings before him are appealable to the lord chancellor.

He hath also his writ of summons to parliament, and sits next to the lord chief justice of England, on the second woolpack: he hath the keeping of the parliament-rolls, and has the rolls-house for his habitation; as also the custody of all charters, patents, commissions, deeds, and recognizances, which, being made of rolls of parchment, gave rise to the name. Anciently he was called *clerk of the rolls*.

Concerning the authority of the *master* of the rolls to hear and determine causes, and his general power in the court of chancery, there were (not many years since) divers questions and disputes very warmly agitated; to quiet which it was declared by stat. 3 Geo. II. cap. 30. that all orders and decrees by him made, except such as

by

by the course of the court were appropriated to the great seal alone, should be deemed to be valid; subject nevertheless to be discharged or altered by the lord chancellor, and so as they shall not be inrolled, till the same are signed by his lordship. Blackst. Com. vol. iii. p. 450.

In his gift are the six clerks in chancery, the examiners, three clerks of the petty-bag, and the six clerks of the rolls-chapel, where the rolls are kept. See ROLLS, CLERK, &c.

MASTER *of a ship*, an officer to whom is committed the direction of a merchant-vessel, who commands it in chief, and is charged with the merchandizes aboard.

In the Mediterranean the *master* is frequently called *patron*, and in long voyages *captain*.

It is the proprietor of the vessel that appoints the *master*, and it is the *master* who provides the equipage, hires the mates, sailors, &c. The *master* is obliged to keep a register of the seamen and officers, the terms of their contract, the receipts and payments, and, in general, of every thing relating to his commission.

MASTER *of a ship of war* is an officer appointed by the commissioners of the navy, to take charge of navigating a ship from port to port, under the direction of the captain. The management and disposition of the sails, the working of a ship into her station in the order of battle, and the direction of her movements in the time of action, and in other circumstances of danger, are also more particularly under his inspection. It is likewise his duty to examine the provisions, and accordingly to admit none into the ship but such as are sound, sweet, and wholesome. He is moreover charged with the stowage; and for the performance of these services, he is allowed several assistants, who are properly termed MATES and QUARTER-*masters*.

MASTER *of the Temple*. The founder of the order of the Templars, and all his successors, were called *magni templi magistri*; and ever since the dissolution of the order, the spiritual guide and director of the house is called by that name. See TEMPLE and TEMPLAR.

MASTER *or keeper of the wardrobe*, an officer in the lord chamberlain's district, who has the direction of all the royal robes, as those of the coronation, St. George's feast, and the parliament-robes; as well as of the wearing apparel, collar of SS's, George and garter, &c.

He has also the charge and custody of all former kings and queens robes, remaining in the Tower; all hangings, bedding, &c. for the king's house; and the charge and delivery of velvet and scarlet allowed for liveries.

He has under him a clerk of the robes, a yeoman, &c. See WARDROBE.

There are also several other officers, under this denomination, as the *master* of the tennis court, with a salary of 132*l.* a-year; *master* of the barges with 100*l.* a-year; *master* of the harriers, with 200*l.* a-year; master of the buck-hounds, with 234*l.* a-year; *master* of the flag-hounds, with 800*l.* a-year; *master*-falconer, with 210*l.* a-year, &c.

MASTER, *burgher*. See BURGHER.

MASTER, *fire*. See FIRE.

MASTER, *quarter*. See QUARTER.

MASTER-*arch*. See ARCH.

MASTER *load*, in *Mining*, a term used to express the larger vein of a metal, in places where there are several veins in the same hill. Thus it often happens, that there are seven, sometimes five, but more usually three veins or loads, parallel to each other, in the same hill. Of these the middle vein is always much the largest. This is called the *master-load*; and the others which lie three, two, or one, on each side of this, are called the concomitants of the *master-load*.

The general breadth of the *master-loads*, in Cornwall, is from three to seven foot; they are seldom larger than this, except in certain peculiar places, as where all the veins meet together, as they sometimes do, and form a knot, from which they separate again, and each takes its peculiar course; the five of such a knot is not easily determined, and it is usually very rich in tin, or the other metal of the mine. The several parts, even of the *master-load*, are not at all regular in breadth, but from six foot, it will, in some places, dwindle to one foot, or even to an inch broad, in a very small space; but the miners are not disheartened at this, for they know it will soon grow wider again, unless really worked out. Phil. Trans. N° 69.

The *master-load* usually lies in the hard rocky or shelly stratum, made up of metalline matter, spars, mundic, and other unprofitable substances, or weeds, as the miners call them, and is, as it were, all along a continued rock; but has many veins and joints as they are called. In some places the matter in which the ore lies is softer, and then it is much more easily worked. In Cornwall they usually allow two shovel-men to three beele-men or pickers; but where the load runs in a softer substance, there must be a greater proportion of the shovellers or carriers away.

There is generally water found about the *load* of the metal: in most places it is met with at some feet deep from the *load's* surface; and it often runs through the heart of the *load*, not in a direct channel, but winningly, in and out, intricately through the veins and joints of the *load*. When the miners have followed a *load* to some depth, and the water begins to be troublesome, as it generally soon is, if there be any in the work, they descend to the bottom of the hill, where they have that conveniency, and at the lowest place begin a little adrift as the convenience of working or driving will permit, scarce half so big as that for a *load*; they carry this on, on a level, till they come to the work itself. In this the use of the dial is needful, which they term PLOMMING and DIALLING.

By this means the exact place of the work is known, where to bring the adit, or where to sink down to make an air-shaft. Though the water is troublesome in the *loads*, yet there is always one great convenience attending it; which is, that where there is water, there is never want of air for the respiration of the miners, and the candles always burn well. But it is also to be observed, that in a soft, loose, quagmire country, the earth sometimes falls in after the workmen, in such a manner as, though it does not choak up the whole shaft, yet it so far stops it, as to render the current of air less free, and the miners find the utmost necessity of opening a shaft for air to respire from the surface. If the soil be so soft as not to be able to support itself in the working, as is sometimes the case in these wet clayey hills, it is necessary to prop it up, as they go on, with boards, posts, and the like. This adds greatly to the expence of mining; but in the working a *master load*, it is often worth while. When the miners are out of heart at the trouble of walling and propping, on this occasion, it sometimes happens, that a dipping of the *load* carries them down into a firmer stratum, and they are at once relieved from all that trouble and danger. See LOAD.

MASTER-PIECE, an exquisite, or extraordinary work, or performance, in any art or science.

MASTER-PIECE, *chef d'œuvre*, is particularly used among the French, for a work which those who aspire to be admitted *masters* in any art or trade, are to perform in presence of the masters, or jurands, of that company, by way of specimen of their capacity.

MASTER-*vault*. See VAULT.

MASTER-*wort*, *imperatoria*, in *Botany*, a genus of the *pentandria digynia* class. Its characters are these: it has an umbellated flower, the principal umbel plain, with no involucrum, which the small ones have; the principal umbel is uniform; and the flowers have five heart-shaped inflexed petals, with five hairy stamina; the germen is situated under the petals, which after becomes a roundish compressed fruit, divided into two parts, and contains two oval bordered seeds. We have but one species of this genus. Miller.

This plant grows naturally on the Alps and Pyrennees and other mountains in Italy, and is cultivated in the gardens of botanists, flowers in June, and the seeds ripen in August. Its black and fibrous roots are only used in medicine, which are said to purge melancholic humours. Hildanus prescribes it also for the cure of a scirrous spleen.

The root of *master-wort*, known in the materia medica, by the name *imperatoria radix*, should be chosen very fair and clean, fresh dried, hard to break, of a brown colour without, and a somewhat greenish one within; and of a strong smell, and aromatic taste. It is usually long, and of the thickness of one's thumb, wrinkled on the surface, and entangled with fibres. It is esteemed cardiac, sudorific, and alexipharmic, good against pestilential and malignant diseases, and against poisons. A decoction of it in wine, used as a gargle, is said to cure the tooth-ach; and externally it is much commended for the itch, and other scabs and ulcers. It is also an ingredient in some of the officinal compositions. Pomet's Hist. of Drugs, p. 44.

This root is likewise good in flatulencies; and, if Hoffman's authority may be depended on, it is one of the most effectual medicines in colics arising from windy causes. The seeds are reckoned by many among the provocatives, and are said by some, to be of the very first class of those medicines. The roots dried, and given in powder, are a powerful remedy in obstructions of the menses; and are of great service in asthmatic cases, tooth-ach, and in many disorders of the head. Simon Pauli tells us, that an ointment made of the fresh roots of this plant boiled in lard, is one of the best remedies known for ring-worms. The root has been also recommended for asthmas, the cramp, and all cold diseases of the nerves.

MASTER-*wort, black, ostruthium*, in *Botany*, a genus of the *pentandria digynia* class. Its characters are these: its flowers grow in an umbel; the involucrum of the general umbel is in one species composed of two large trifid leaves, and two entire, in another species of several small leaves; the involucrum of the small umbels is composed of many small-pointed leaves, which are longer than the umbels, coloured and spread open; the empalement of the flower is permanent, erect, and cut into five short acute segments; the flowers are composed of five petals, erect, bifid, and bent inward: the oblong germen is situated below the receptacle, and becomes an oval blunt channelled fruit, divided into two parts, having two oblong oval seeds, inclosed in the cover. Miller enumerates three species, and Linnæus only two, viz. the greater and less: these plants are seldom preserved in botanic gardens, as there is no great beauty in their flowers: all of them grow naturally upon the Alps.

MASTER-*wort*, a large *yaw* sometimes remaining after salivation. See YAWS.

MASTICA *de fobo*, in the *Materia Medica*, the name given by the Indians to the stone commonly known among authors by the name of *pedro del porco*, a sort of BEZOAR taken out of the gall-bladder of an Indian boar. The Indians, and many of the European nations, esteem this one of the greatest medicines in the world in pestilential diseases, and the small-pox.

MASTICATION, MASTICATIO, in *Medicine*, the action of chewing, or of agitating the solid parts of our food between the teeth, by means of the motion of the jaws, the tongue, and the lips, whereby it is broken into small pieces, impregnated with saliva, and so fitted for deglutition, and a more easy digestion in the stomach.

The mixture of saliva with the food is of absolute necessity; for the saliva, imbibed within the parts of it, dissolves the salts hid in them; and by so doing, prepares the food for fermentation in the stomach. The food, therefore, has the beginning of its digestion from the saliva, and its conclusion from the ferment in the stomach.

MASTICATORIES, MASTICATORIA, in *Medicine*, are such remedies as are taken in at the mouth, and chewed, in order to promote the evacuation of the salival humour; as tobacco, ginger, pepper, sage, rosmary, thyme, mastich, &c.

MASTICH *tree*, TURPENTINE-*tree*, or PISTACHIA-*nut-tree*, in *Botany*, a genus of the *dioecia pentandria* class. Its characters are these: male and female flowers grow upon different plants; the male flowers are disposed in loose sparsed katkins, having five pointed empalements, but no petals; they have five small stamina, terminated by oval, four-cornered, erect summits; the female flowers have five small trifid empalements, but no petals; they have each a large oval germen, supporting three reflexed styles, crowned by thick prickly stigmas; the germen turns to a dry berry, or nut, including an oval smooth seed. Linnæus enumerates five, and Miller nine species. The PISTACHIA nut, which grows upon one species of this tree, is better known in England than the tree which bears it, which grows naturally in Arabia, Persia, and Syria, whence the nuts are annually brought to Europe. The species which is called the common *mastich* tree, and is known by the Latin *lilli, or lentiscus*, grows naturally in Spain, Portugal, and Italy, and being an ever-green, is sometimes preserved in green-houses in England, through the winter.

The true *mastich* tree of the Levant, which furnishes the gum *mastich*, is, according to Miller, another species. From transverse incisions made in the bark of the tree, about the beginning of August, the *mastich* resin or gum, exudes in drops, which running down, and concreting on the ground, are thence swept up. The tree is raised also in several parts of Europe; but no resin has been observed to issue from it in these climates. It has its name *mastich*, from *masticare, to chew*, because it is thus used in Chio, and by the Turks, especially the women, for sweetening the breath, and strengthening the gums and teeth: and by producing a copious excretion of saliva, it proves serviceable in catarrhous disorders. This resin has a light agreeable smell, especially when rubbed or heated. It is almost totally soluble in spirit of wine, yielding a solution of a pale yellow colour, but not at all in water. It becomes soft and tough like wax, by being chewed. *Mastich* is recommended in doses from half a scruple to half a dram, as a mild corroborant and astringent, in old coughs, haemoptyses, diarrhœas, weakness of the stomach, &c. It is given either in substance, divided by other materials; or dissolved in spirit and mixed with syrups; or dissolved in water into an emulsion, by the intervention of gum Arabic or almonds. It is also an ingredient in varnishes. See VARNISH.

The jewellers mix *mastich* with turpentine and ivory-black, and lay it under their diamonds, to give them a lustre.

Mastich is chiefly the product of Chio: the trees that yield it are there cultivated with as much care as the vines. It brings in a revenue of eighty thousand ducats per annum to the grand signior. There is also a kind of *mastich* brought from Egypt, which serves to sophisticate camphor. The gum *mastich* is in small granules, and white, if good; though age makes it turn yellowish.

The Arabian writers, Avicenna and Serapion, in their chapters of the turpentine tree, often mention the lentisk and its resin, which they say was very much like the resin of the common turpentine tree. But beside this, Avicenna has a peculiar chapter on *mastich*; whence it should seem, that by the name lentisk they do not mean the tree which produces *mastich*, but some peculiar species of the turpentine tree.

Avicenna distinguishes two kinds of *mastich*, the one called *rumi*, and the other *cupri*: the *rumi* came from the island of Chio, and was white; the *cupri* was of a blackish colour, and was brought from Egypt.

MASTICH *herb, master-thyme, marum vulgare*, in *Botany*, a name given to one of the species of SATUREIA.

It is a plant that grows naturally in Spain, in dry gravelly grounds, and in the like soils bears the ordinary winters of our climate. It flowers in June, and its flowers are small, white, and standing in hairy bristly empalements: the whole plant has a grateful odour.

This plant is employed chiefly, like the Syrian *mastich*, as an errhine. It is considerably pungent, though less so than the other.

MASTICH, *Syrian herb, marum Syriacum*, is a species of *teucrium*, or *tree* GERMANDER, which grows naturally in Syria and in the kingdom of Valencia: the flowers, which are of a bright red colour, appear in July and August, but are not succeeded by seeds in England. This plant is easily propagated by slips or cuttings, planted in the summer months on a bed of light loamy earth, where they are to be carefully shaded, till they have taken root; after which they are to be removed into pots or borders. The cats are very fond of this plant, and tear it to pieces; but it is observed, that though they never spare a plant that grows single or where few grow, they will seldom touch them when planted in large clusters. Miller.

The leaves of this plant have a bitterish, aromatic, very pungent taste; and when rubbed a little, yield a quick piercing smell, which provokes sneezing. They have been chiefly made use of as an ingredient in sternutatory powders, though, from their sensible qualities, they promise to be applicable to more important purposes, and to have no ill title to the stimulating, attenuating, deobstruent, antiseptic virtues, ascribed to them by Wedelius.

MASTICH, *Indian, schinus*, in *Botany*, a genus of the *dioecia decandria* class. Its characters are these: the flower has a small empalement, with five indentures at the top; it has five small petals, which spread open, and nine or ten slender stamina, with a roundish germen supporting a short thick style, crowned by a single stigma; the germen afterwards turns to a globular berry with one cell, inclosing one globular seed. There are two species, which grow naturally in the southern parts of America. Miller.

A decoction of the bark of this tree, makes a fomentation of extraordinary efficacy in pains of the legs, and inflations. Of the small branches are made serviceable tooth-picks. Of the fruit boiled in water, according to the measure of the decoction, they prepare either a wine, a very good sort of drink, vinegar, or honey. A decoction of the leaves gives relief in pains proceeding from cold causes. Raii Hist. Plant.

MASTICHE *terra, mastich earth*, a name given by some of the old writers on the materia medica to the Chio earth, or TERRA *Chia*. The reason of this strange appellation seems to have been, that the finest *mastich* coming from the island of Chio, had obtained the name of *Ros*, or *Chios*, and *mastich* and *Chia* being thus become, in one sense, synonymous words, the use of them was, in this manner, carried much farther, and the earth of that island called by the name of the *gum*.

The Arabians seem to explain this very well, in their name of this earth; they not calling it *mastich earth*, but *thin beled almastichi*, that is *terra resinæ mastichis*, the earth of the country where *mastich* is produced.

MASTICOT, or *yellow lead*, is the calx or ashes of LEAD, gently calcined, by which it is changed to a yellow, or lighter, or deeper tint, according to the degree of calcination.

Massicot is sometimes used by painters, and it serves medicinally as a drier in the composition of ointments or plasters.

The *massicot* which is used by the Dutch as the ground of their

their GLAZING, is prepared by calcining a mixture of one hundred weight of clean sand, forty-four pounds of soda, sold with us under the name of barilla, and thirty pounds of pearl-ashes.

MASTIFF-*dog*, or *hand-dog*, *villaticus*, or *catenarius*, is a species of great size and strength, and a very loud barker. Manwood says, that it derives its name from *masse theefe*, being supposed to frighten away robbers by its tremendous voice. Great Britain was formerly to noted for its *mastiffs*, that the Roman emperors appointed an officer in this island, with the title of *Procurator Cynegii*, whose sole business was to breed, and transmit from hence to the amphitheatre, such as would prove equal to the combats of the place. Strabo, lib. iv. tells us, that the *mastiffs* of Britain were trained for war, and used by the Gauls in their battles.

MASTIGADOUR, or SLABBERING-BIT, in the *Manege*, is a snaffle of iron, all smooth, and of a piece, guarded with pater nosters, and composed of three halves of great rings, made into demi-ovals of unequal bignefs, the leſſer being inclosed within the greateſt, which ought to be about half a foot high. A *maſtigadour* is mounted with a head-ſtall and two reins. A horſe, by champing upon the *maſtigadour*, keeps his mouth freſh and moiſt.

To put a horſe to the *maſtigadour*, is to ſet his croupe to the manger, and his head between two pillars in the ſtable. Horſes that uſe to hang out their tongues cannot do it when the *maſtigadour* is on; for that keeps their tongue ſo much in ſubjection, that they cannot put it out.

MASTIGOPHORI, Μαστιγοφοροι, among the Greeks, certain officers appointed to preſerve the peace, and correct ſuch as were diſorderly at the Olympic games.

MASTOIDES, Μαστοειδης, from μαστος, *nipple*, and ειδος, *figure*, in *Anatomy*, the ſame with *mammillaris*, is applied to ſuch proceſſes in the body as have the appearance of breaſts, or dugs, ariſing from a broad baſis, and terminating in an obtuſe top.

MASTOIDES is ſometimes alſo applied to thoſe muſcles which ſtoop the head, proceeding from the neck-bone and breaſt-bone, and terminating in the proceſs mammiformis.

MASTON, in *Botany*, a name by which Pliny and ſome other authors have called the *ſcabioſa*, or *ſcabious*, a blue-flowered plant, common among corn.

MAT, in *Sea Language*. See MATTS.

MATCH, from the Saxon *macca*, *a companion*, becauſe, ſays Johnſon, the *match* is companion to the gun; a kind of rope, ſlightly twiſted, and prepared to retain fire, for the uſes of artillery, mines, fire-works, &c.

It is made of hempen tow, ſpun on the wheel like cord, but very ſlack; and is compoſed of three twiſts, which are afterwards again covered with tow, ſo that the twiſts do not appear; laſtly, it is boiled in lees of old wines, whence its colour. This, when once lighted at the end, burns on gradually and regularly, without ever going out, till the whole be conſumed.

Since fuſees have been introduced in lieu of *match*-lock muſkets, the conſumption of *match* has been much leſs conſiderable than before.

MATCHING, in the *Wine Trade*, the preparing veſſels to preſerve wines and other liquors, without their growing ſour or vapid. See WINE.

The method of doing it is this: melt brimſtone in an iron ladle, and, when thoroughly melted, dip into it ſlips of coarſe linen cloth; take theſe out, and let them cool. This is what the wine-coopers call *match*. Take one of theſe *matches*, ſet one end of it on fire, and put it into the bung-hole of a caſk; ſtop it looſely, and thus ſuffer the *match* to burn nearly out; then drive in the bung tight, and ſet the caſk aſide for an hour or two. At the end of this time examine the caſk, and you will find that the ſulphur has communicated a violently pungent and ſuffocating ſcent to the caſk, with a conſiderable degree of acidity, which is the gas, and acid ſpirit of the ſulphur. The caſk may, after this, be filled with a ſmall wine, which has ſcarce done its fermentation, and bunging it down tight, it will be kept good, and will ſoon clarify. This is a common and a very uſeful method; for poor wines could ſcarce be kept potable, even a few months, without it. Nor could ſtums be prepared in large quantities without this help. Shaw's Lectures, p. 191.

MATE *of a merchant ſhip*, is the officer who commands in the abſence of the MASTER, and ſhares the duty with him at ſea; being charged with every thing that regards the intended management of the ſhip, the direction of her courſe, and the government of her crew.

MATE *of a ſhip of war*, is an officer under the direction of the MASTER, by whoſe choice he is generally appointed, to aſſiſt him in the ſeveral branches of his duty.

Accordingly, he is to be particularly attentive to the navigation in his watch, &c. to keep the log regularly, and examine the line and glaſſes, by which the ſhip's courſe is meaſured, and to adjuſt the ſails to the wind, in the fore-part of the ſhip. He is alſo to attend diligently to the cables, ſeeing that they are well coiled and kept clean, when laid in the tiers, and ſufficiently ſerved, when employed to ride the ſhip. Finally, he is to ſuperintend and aſſiſt at the ſtowage of the hold, taking eſpecial care that all the ballaſt and proviſions are properly ſtowed therein.

The number of *mates* allowed to ſhips of war and merchantmen, is always in proportion to the ſize of the veſſel. Thus a firſt-rate man of war has ſix *mates*, and an Eaſt Indiaman the ſame number; a frigate of twenty guns and a ſmall merchant-ſhip have only one in each; and the intermediate ſhips have a greater or ſmaller number, according to their ſeveral ſizes, or to the ſervices on which they are employed. Falconer.

Other officers have alſo aſſiſtants, called *mates*; as the ſurgeon, gunner, carpenter, boatſwain, cook, and corporal.

MATER *metallorum*, in *Natural Hiſtory*, a name given by the Saxon mineraliſts, and thoſe of ſome other places, to a peculiar kind of MARCASITE or MUNDIC, which they ſuppoſe, according to the expreſſion, to be the mother or parent of metals.

The marcaſite they call by this name is the common yellow kind, but in a ſoft ſtate, it being uſually mixed with ſome poor ore of iron, or with ſome ſtony matter, which has made it concrete looſely and irregularly, and it is found ſometimes formed into thin undulated plates, and ſometimes into complex maſſes; but is always cavernous or ſpungy, or full of ſmaller or larger holes. Theſe are often empty: but in ſome pieces they contain parcels either of the pure native metals, or of rich ores. Pieces of native copper are found in ſome, and ores of iron and tin in others. And it is ſaid in Saxony, that native ſilver, in thin plates, is found in ſome few.

MATER *tenuis*, or *Pia* MATER. See MENINGES, and PIA.

MATER *dura*. See MENINGES, and DURA.

MATERFILON, in *Botany*, a name given by ſome authors to the *juncus nigra*, or common knapweed. Our Engliſh name *matfellon*, ſeems a corruption of this. See CENTAURY.

MATERIA. See MATTER.

MATERIA *chemica*, a term uſed by authors to expreſs ſuch bodies as are the peculiar objects of chemical experiments. The *materia chemica*, in a larger ſenſe, takes in all the bodies of the globe, all theſe being the ſubjects of chemiſtry, in its extenſive ſenſe; but the curious in chemical researches may be deſirous of knowing, in general, what bodies they ought to procure, and have in readineſs for them. Dr. Shaw has given a liſt of theſe for his Portable Laboratory, which will ſerve in general as well as on that particular occaſion.

This collection being diſtributed under proper claſſes, will come into a ſmall compaſs, and may be conveniently carried either by land or ſea, along with that uſeful furnace, and its neceſſary apparatus.

The natural arrangement of the *materia chemica* is into the general diviſion of animal, vegetable, and mineral ſubſtances. But thoſe who are deſirous of a larger collection, may enlarge the number of general diviſions, according to Becher's method, by which all chemical ſubjects are arranged into nine general claſſes; metals, minerals, decompounds, ſalts, gums, earths, ſtones, ſpirits, and oils.

The claſs of metals contains gold, ſilver, copper, iron, tin, and lead; and all theſe are to be kept both in their natural and artificial ſtate; that is, in their ores, and as ſeparated from them for human uſes. To theſe natural metals are to be added the artificial or compound ones, viz. pewter, bell-metal, braſs, gun-metal, pot-metal, Bath-metal, Wells-metal, prince-metal, London-metal, white copper, white gold, and yellow ſilver. Under minerals are included, antimony, biſmuth, zinc, manganeſe, cobalt, zaffer, ſmalt, arſenic, orpiment, mercury, native cinnabar, and ſulphur. All theſe are to be kept both in their natural ſtate as dug out of the earth, and as purified.

The decompounds of minerals include aurum fulminans, luna cornea, the calxes of gold and ſilver, ultramarine, diſtilled verdegris, burnt copper, putty, or calcined tin, ſugar of lead, cadmia, tutty, black-lead, red-lead, litharge, white-lead, glaſs of lead, ſimple and martial regulus of antimony, glaſs and cinnabar of antimony, the preparations of quick-ſilver, as ſublimate, precipitate, and the reſt. The ſame ſort of arrangement may alſo take in the ſeveral kinds of decompounds of animal and vegetable ſubſtances. Shaw's Port. Laborat.

The claſs of ſalts takes in ſea-ſalt, nitre, alum, vitriol, borax, tartar, ſugar, potaſh, and the compound ſaline fluxes for ſtubborn ores. And to theſe are to be added the tribe of artificial ſalts, of which number are the tartа-

rum vitriolatum, fixed nitre, soluble tartar, terra foliata tartari, nitrum nitratum, sal ammoniac, Epsom salts, volatile salts, and several others of a similar nature.

Under the gums are ranked pitch, resin, turpentine, wax, camphor, amber, pit-coal, jet, and all bitumens, balsams, and inspissated juices.

Among the earths are taken in ores, washed ores, fluds, calxes of metals, lime, plaister, gypsum, chalk, boles, shells, sand, and the fusils commonly and properly called earths, whether they be of the calcarious or of the vitrifiable kinds; that is, whether in the fire they are converted into a sort of lime, or run into a glass.

Stones include flints, pebbles, quarry stone, crystal, talc, the vulgar stones, and all the gems from the diamond down to the spars.

Lastly, under spirits and oils come aqua regis, aqua fortis, oil of vitriol, spirit of salt, spirit of nitre, spirit of sulphur, spirit of alum, spirit of vinegar, spirit of wine, spirit of urine, spirit of tartar, spirit of turpentine, oil of tartar per deliquium; the essential oils of nutmegs, cloves, and the like; the expressed oils of olives, almonds, linseed and the like; and the compound oils; as butter of antimony, artificial balsam, &c.

It is easy to see that this sort of elassing is not fit for the naturalist, who studies bodies for their natural qualities, not indeed for the nice distinguisher of any kind; but in this manner Becher advises the young operator in chemistry, to procure to himself a sort of artificial alphabet of nature, and this will serve the purpose very well, where no more is meant than a mere *materia chymica*, to be put in such order, that it may be readily had recourse to in all its parts. With this the young operator is to proceed regularly, as he would do in learning a language. Forming first syllables out of the joining of two or more letters of this alphabet, and then words, by combining these first sets together, and finally, whole discourses; that is, forming their various simple bodies into mixts, compounds and decompounds. Becher's Phyl. Subter. p. 179.

To avoid miscarriages, and prevent being imposed upon, it will be very proper to cultivate a knowlege of the productions of nature in their crude state, and peculiar places of growth, where being first viewed and examined before they are gathered or dug up, an exact knowlege of them as nature furnishes them, may be procured. For want of this previous qualification, men, otherwise of great sagacity, have erred in their operations, and perhaps blamed the original author of a process, in which they miscarry; while they are all the while using a wrong subject, or an adulterated or imperfect one, instead of the true. From this mistake alone, numberless complaints have arisen of the failure and uncertain success in the processes and experiments recorded even by the best authors.

The person who would work in chemistry with pleasure and success, should make a sufficiently copious collection of a *materia chymica* of this kind, all the particulars of which he is well assured of, as to their genuineness and perfection in their kinds. These being always ready, will prevent the necessity of sending to the druggist at every turn, where the things sent for are often either not to be had, or only in a sophisticated state; when this alphabet of nature, composed of the several materials of chemical researches, is like the letter in a printing-house, distributed and lodged in proper cells, it may readily be drawn out for use as occasion requires. It is impossible to express with how little expence and trouble, yet with how great profit and pleasure, numerous experiments, and those of the most difficult kind may be made, when the operator has, in this manner, all his materials about him. Becher tells us, that he has, in this manner, gone through fifty experiments in a day; and, while writing on chemical subjects, if any difficulty or uncertainty occurred, he immediately got up from his desk, made the necessary experiment, and sat down again to write the certain fact: so that he affirms, there was very little more trouble in making the experiment at the fire, than in describing the process by the pen.

MATERIA *subtilis*, denotes a fine subtile matter, which the CARTESIANS suppose to pervade and penetrate freely the pores of all bodies, and to fill up all the pores, so as not to leave the least vacuity, or interstice, between them.

This machine they have recourse to, to support the doctrine of an absolute plenum, and to make it consistent with the phenomena of motion, &c. and, accordingly, they make it act and move at pleasure, but in vain: for, were there any such matter, in order for it to be able to fill up the vacities of other bodies, it must, itself, be entirely void of any, i. e. it must be perfectly solid, vastly more solid than gold, and, therefore, more ponderous, and resist vastly more, which is inconsistent with phenomena. See VACUUM, and PLENUM.

Yet Sir Isaac Newton allows of the existence of a subtile matter, or medium, vastly finer than *air*, penetrating the closest bodies, and contributing to the production of many of the phenomena of nature. The existence of such a matter he argues from the experiment of two thermometers, which being inclosed in glass vessels, "one "of them, exhausted of its air, and both carried from "a cold to a warm place, the thermometer *in vacuo* "grows warm, and rises, almost as soon as that in the "air; and, if returned into the cold place, both cool "and fall about the same. Hence, says he, is not the "heat of the warm room conveyed through the vacuum "by the vibrations of a much subtiler medium than air, "which remained *in vacuo* after the exhaustion of the "air? And is not this medium the same whereby light "is refracted, reflected, &c?"

MATERIAL, denotes something composed of MATTER. In which sense the word stands opposed to IMMATERIAL. The Epicureans, Spinosists, &c. own no other but *material* substances. See SUBSTANCE. Among causes, some are *material*, others are formal. See CAUSE.

Material causes, having no understanding or liberty, must always act in the same manner, when under the same circumstances. Philosophers and divines dispute, whether or no there be any *material* forms really distinct from matter? See FORM. The Valentinians formerly applied the term *material* to all people but those of their own sect; asserting, that their souls perished with their bodies. Thus also the Stoics maintained, that none but the souls of their wise men survived the body.

MATERIAL *circle*. See CIRCLE.

MATERIAL *spirit*. See OBJECT.

MATERIALISTS, a sect in the ancient church, composed of persons, who, being prepossessed with that maxim in the ancient philosophy, *Ex nihilo nihil fit, Out of nothing nothing can arise*, had recourse to an eternal matter, on which they supposed God wrought in the creation; instead of admitting God alone as the sole cause of the existence of all things.

Tertullian vigorously opposes the doctrine of the *Materialists*, in his treatise against Hermogenes, who was one of their number.

Materialist is also a name given to those who maintain that the soul of man is material; or that the principle of perception and thought is not a substance distinct from the body, but the result of corporeal organization. See SOUL. There are others, called by this name, who have maintained that there is nothing but MATTER in the universe; and that the Deity himself is material. See SPINOSISM.

MATFILON, in *Botany*. See CENTAURY.

MAT-*weed*, in *Botany*. See LYCHNIS.

MATHEDORAM, a name by which some chemists have called *sal gemm*.

MATHEMATICAL *point*. See POINT.

MATHEMATICAL *sect*, in the *History of Learning*, is one of the two leading philosophical sects, which appeared towards the beginning of the seventeenth century: this sect directed its researches by the principles of Gassendi, and sought after truth by observation and experience. The disciples of this sect denied the possibility of erecting on the basis of metaphysical and abstract truths, a regular and solid system of philosophy, without the aid of assiduous observation and repeated experiments, which are the most natural and effectual means of philosophical progress and improvement. The advancement and reputation of this sect, and of natural knowledge in general, were much owing to the plan of philosophizing, proposed by lord Bacon, to the establishment of the Royal Society in London, to the genius and industry of Mr. Boyle, and to the unparalleled researches and discoveries of Sir Isaac Newton. Barrow, Wallis, Locke, and many others were of this sect. See CORPUSCULAR, EXPERIMENTAL, and NEWTONIAN *Philosophy*.

The other sect of philosophers was the METAPHYSICAL.

MATHEMATICS, the science of quantity; or a science that considers magnitudes either as computable, or measurable.

The word in its original, *μαθησις*, signifies *discipline*, or *science*, in the general, and seems to have been applied to the doctrine of quantity, either by way of eminence, or because, as this had the start of all other sciences, the rest took their common name from it.

For the origin of the *mathematics*, Josephus dates it before the flood, and makes the sons of Seth observers of the course and order of the heavenly bodies: he adds, that to perpetuate their discoveries, and secure them from the injuries either of a deluge, or conflagration, they had them engraven on two pillars, the one of stone, the other of brick; the former of which, he says, was standing in Syria in his days.

The first who cultivated *mathematics* after the flood, were the

the Assyrians and Chaldeans; from whom the same Josephus adds, they were carried by Abraham to the Egyptians; who proved such notable proficients, that Aristotle makes no scruple to fix the first rise of *mathematics* among them. From Egypt, five hundred eighty-four years before Christ, they passed into Greece through the hands of Thales, who, having learned geometry of the Egyptian priests, taught it in his own country. After Thales, comes Pythagoras; who, among other mathematical arts, paid a peculiar regard to arithmetic; fetching the greatest part of his philosophy from numbers: he was the first, as Laertius tells us, who abstracted geometry from matter; and to him we owe the doctrine of incommensurable magnitude, and the five regular bodies, besides the first principles of music and altronomy. Pythagoras was succeeded by Anaxagoras, Oenopides, Briso, Antipho, and Hippocrates of Chios; who all applied themselves particularly to the quadrature of the circle, the duplicature of the cube, &c. but the last with most success: this last is also mentioned by Proclus, as the first who compiled elements of *mathematics*.

Democritus excelled in *mathematics* as well as physics; though none of his works, in either kind, are extant: the destruction of which some authors ascribe to Aristotle. The next in order is Plato, who not only improved geometry, but introduced it into physics, and so laid the foundation of a solid philosophy. Out of his school proceeded a crowd of *mathematicians*. Proclus mentions thirteen of note; among whom was Leodamus, who improved the analysis first invented by Plato; Theaetetus, who wrote elements; and Archytas, who had the credit of being the first who applied *mathematics* to real use in life. These were succeeded by Neocles and Theon, the last of whom contributed to the elements. Eudoxus excelled in arithmetic and geometry, and was the first founder of a system of astronomy. Menechmus invented the conic sections, and Theudius and Hermotimus improved the elements.

As for Aristotle, his works are so stored with *mathematics*, that Blancanus compiled a whole book of them; out of his school came Eudemus and Theophrastus; the first of whom wrote of numbers, geometry, and invisible lines; the latter a mathematical history. To Aristeus, Isidorus, and Hypsicles, we owe the books of solids; which, with the other books of elements were improved, collected, and methodized by Euclid, who died two hundred and eighty-four years before Christ.

A hundred years after Euclid, came Eratosthenes and Archimedes. Contemporary with the latter was Conon, a geometrician and astronomer. Soon after came Apollonius Pergaeus, whose Conics are still extant. To him are likewise ascribed the fourteenth and fifteenth books of Euclid, which are said to have been contracted from Hypsicles. Hipparchus and Menelaus wrote on the solutions in a circle, the latter also on spherical triangles; Theodosius's three books of spherics are still extant. All these, Menelaus excepted, lived before Christ.

A. D. 70, Ptolemy of Alexandria was born; the prince of astronomers, and no mean geometrician: he was succeeded by the philosopher Plutarch, of whom we have still extant some mathematical problems. After him came Eutocius, who commented on Archimedes, and occasionally mentions the inventions of Philo, Diocles, Nicodemus, Sporus, and Heron, on the duplicature of the cube. To Ctesibes of Alexandria we owe our pumps; and Geminus, who came soon after, is preferred by Proclus to Euclid himself.

Diophantus of Alexandria was a great master of numbers, and the first inventor of algebra: and among others of the ancients, Nicomachus is celebrated for his arithmetical, geometrical, and musical works; Serenus, for books on the section of the cylinder; Proclus, for his comments on Euclid; and Theon has the credit among some, of being author of the books of Elements, ascribed to Euclid. The last to be named among the ancients, is Pappus of Alexandria, who flourished A. D. 400, and is celebrated for his books of *mathematical* collections still extant.

See the progress of each branch of *mathematics*, with the authors who have written on it, under the respective heads; as GEOMETRY, ALGEBRA, ASTRONOMY, &c.

Mathematics are distinguished, with regard to their end, into

MATHEMATICS, *speculative*, which rest in the bare contemplation of the properties of things: and

MATHEMATICS, *practical*, which apply the knowlege of those properties to some uses in life.

With regard to their object, *mathematics* are divided into *pure* or *abstract*, and *mixed*.

MATHEMATICS, *pure*, consider quantity abstractedly, and without any relation to matter or bodies.

MATHEMATICS, *mixed*, consider quantity, as subsisting in material being; e. g. length in a road, breadth in a river, height in a star, or the like.

Pure mathematics, again, either consider quantity as discrete, and so computable, as arithmetic; or as concrete, and so measurable, as geometry and trigonometry.

Mixed mathematics are very extensive, and are distinguished by various names, as the subjects they consider, and the views wherein people take them, vary; it being sufficient to determine an art to be a branch of *mixed mathematics*, that *pure mathematics* are applicable thereto, i. e. that it may be explained and demonstrated from the principles of arithmetic and geometry. Such are

MECHANICS, which consider motion, or the laws of moving bodies. HYDROSTATICS, which consider the laws of fluids, or of bodies gravitating in fluids. PNEUMATICS, the air, with regard to the laws and mensuration thereof. HYDRAULICS, the motion of fluids. OPTICS, direct light or vision. CATOPTRICS, reflected vision. DIOPTRICS, refracted vision. PERSPECTIVE, the images of objects, in order to delineate or represent them. ASTRONOMY, the universe, and the phenomena of the heavens. GEOGRAPHY, the earth, both as in itself, and in its affections. HYDROGRAPHY, the sea, principally as navigable. CHRONOLOGY, time, with regard to the measuring and distinguishing thereof. GNOMONICS, or DIALLING, shadows, in order for determining the hour of the day. PYROTECHNY, artificial fires, with regard both to diversion, and to the uses of war. *Military* ARCHITECTURE, the strength of places, with regard to their defence against an enemy. *Civil* ARCHITECTURE, (now become a branch of *mathematics*) or buildings. MUSIC, sounds, and their effects on the ear.

For the elements of each of these, see the respective heads: and for an accurate system of all the parts above mentioned (music alone excepted) orderly digested, and clearly demonstrated, see the excellent Wolfius's *Elementa Matheseos Universæ*.

MATHURINS, in *Ecclesiastical History*, a name given to the brethren of the Holy Trinity, from their having a monastery at Paris, erected in the place where there is a chapel confecrated to St. *Mathurin*. See TRINITARIANS.

MATITES, in *Natural History*, the name of a stone described by several authors. The characters they give of it are, that it is of a pale greyish colour, and of the form of the nipples of a woman's breast, several of these nipples appearing upon one stone.

There have been many absurd and idle conjectures, as to the origin of this stone; but it may be easy to account for its figure on very plain and natural principles. We find in the earth many stones, resembling exactly the figures of shells of various kinds, and parts of other animals. These have, in general, once been the things they thus represent petrified, or altered into the nature of stone, by the infinuation of stony particles into their pores.

Among these, none are so frequent as the remains of the *echini marini*, or sea-eggs, as we call them. These we find in various forms, sometimes single spines, sometimes whole shells, and sometimes only parts of shells preserved. It is well known, that all the *echini marini* have spines or spikes, whence they have their name; and in many of the species which we find recent on the shores, these spines are joined to the body of the shell by a small protuberance, which, from its resemblance to a nipple, we call *papillæ*. Now we frequently find these papillæ delineated in crux, in pebbles, and other stones, sometimes singly, and sometimes in numbers together, in the form in which they adhered to the shell. We find, in other fossils, that whatever shell, &c. is sometimes delineated in crux on stone, is also sometimes done in the elevated manner; and it is plain, that there needs no more to the formation of one of these *matites* than the petrifaction of a piece of the shell of one of those *echini* which have large papillæ, such as those of the Red Sea, with some of its papillæ upon it. As to the colour, it is not to be limited to grey alone, but may be various as the colours of stones, since any species of stone may have gone to the formation of it; and whatever colour the stony matter was, of that will the *matites* be.

MATKENELTZEL, in *Ornithology*, the name of a bird approaching to the SNIPE kind, and called by Gesner *gallinula erythra*; and by the common people of Germany, *mattkern*. It is all over of a reddish or ruddy hue, except the belly, which is white; on the back the colour is more dusky, and is variegated with black spots. On the wings the colour is much fairer and clearer, some of the longer feathers of them approaching to the colour of the painters red earth, called reddle. It is common in watery places, in many parts of Germany and Italy.

MATO, in *Natural History*, the name of a tree growing

both in the East and West-Indies, and bearing a fruit of the size of an apple, and covered with a thick and tough red skin. This is called by some, the wild MANGOUSTAN. Its fruit perfectly resembles that of the mangoustan in figure, but is not eatable. Mem. Acad. Par. 1699.

MATORIUM, a word used by some of the chemical writers to express the *gum ammoniacum*, and by others *galbanum*.

MATRASS, MATRACIUM, or BOLT-HEAD, a glass vessel, used by chemists in digestions, and other operations.

The *matrass* is made in form of a bottle somewhat bellied in the middle, with a long narrow neck; it is coated with earth, when it is to be placed on a very hot fire. And when it is required it should be stopped very close, they seal it hermetically.

The *matrass*, used in assaying, is a vessel of very pure and transparent glass, not too thick at the bottom, which would make it apt to burst in the fire. It is, for this use, to be about eight or ten inches high, and to have an orifice scarce so much as half an inch wide, lest the matters contained in it, being in a violent state of ebullition, should either rise over the mouth of the vessel, or at least be partly thrown out in form of small drops, like a thin rain, which drops always carry some of the metal with them. The bottom is capacious enough, when it will hold an ounce or two of aqua fortis, and the height of the vessel is of a farther use in making a greater repercussion of the fumes. The mouth ought also to be turned backwards, in form of a broad lip, that the solutions, when poured out, may not run down the sides of the vessel. Cramer, Art of Ass. p. 68.

Matrasses are also used as receivers: as to their form, some are spherical, others flattened at the bottom, and others in the shape of an egg, called PHILOSOPHICAL *eggs*. The most convenient of all, when only a small quantity of matter is used, are bottles of thin glass, called medical phials; because they are cheap, made of good glass, and may be quickly heated, so that the liquor contained in them shall boil without danger of being broken. See *Tab.* II. *Chemistry*, *fig.* 22 and 23.

MATRICARIA, in *Botany*. See FEVERFEW.

MATRICE, or MATRIX. See MATRIX.

MATRICE, or MATRIX, in *Dying*, is applied to the five simple colours, whence all the rest are derived or composed. These are, the black, white, blue, red, and yellow or root colour. See DYING.

MATRICE, or MATRICES, used by the *Letter-founders*, are those little pieces of copper or brass, at one end whereof are engraven, dent-wise, or *en creux*, the several characters used in the composing of books.

Each character, virgula, and even each point, in a discourse, has its several *matrix*; and, of consequence, its several puncheon to strike it. They are the engravers on metal, that cut, or grave, the *matrices*.

When types are to be cast, the *matrice* is fastened to the end of a mould, so disposed, as that when the metal is poured on it, it may fall into the creux, or cavity, of the *matrice*, and take the figure and impression thereof. See *Letter*-FOUNDERY.

MATRICES, used in *Coining*, are pieces of steel, in form of dyes, whereon are engraven the several figures, arms, characters, legends, &c. wherewith the species are to be stamped.

The engraving is performed with several puncheons, which being formed in relievo, or prominent, when struck on the metal, make an indented impression, which the French call *en creux*. See the manner hereof under ENGRAVING *on Steel*. See also COINING.

MATRICULA, a register kept of the admission of officers, and persons entered into any body, or society, whereof a list is made. Hence those who are admitted into our universities, are said to be *matriculated*.

Among ecclesiastical authors, we find mention made of two kinds of *matriculæ*; the one containing a list of the ecclesiastics, called *matricula clericorum*; the other of the poor subsisted at the expence of the church, called *matricula pauperum*.

MATRICULA was also applied to a kind of alms-house, where the poor were provided for. It had certain revenues appropriated to it, and was usually built near the church; whence the name was also frequently given to the church itself.

MATRIMONY. See ESPOUSALS, and MARRIAGE.

MATRISYLVA, in *Botany*, a name by which some authors call the common honey-suckle, or wood-bind, and others the wood-ruffe.

MATRIX, in *Anatomy*, the womb, or that part of the female of any kind, wherein the fœtus is conceived, and nourished till the time of its delivery. See WOMB, UTERUS, FOETUS, &c.

MATRIX, *suffocation of the*. See SUFFOCATION.

Speculum MATRICIS. See SPECULUM.

MATRIX is also applied to places proper for the generation of vegetables, minerals, and metals.

Thus, the earth is the *matrix* wherein seeds sprout; and marcasites are by many confidered as the *matrices* of metals.

The *matrix* of ORES is the earthy and stony substances in which these metallic matters are inveloped: these are very various, frequently spar, quartz, fluors, or horn-blend.

MATRIX *fossilis*, in *Natural History*, a name given by Hartman, and some other authors, to a sort of substance resembling fossil wood, or the barks of trees, common in the cliffs of the shores of the Baltic, and found in digging all over Prussia. This is the bed in which the fossil amber of that kingdom is lodged, and it is supposed to have no small share in the production or formation of that fossil. The workmen who dig for amber always make this their guide, and follow the veins of it, never searching any where else for the AMBER. The very surface of this fossil substance is often covered with a kind of amber; but this is poor, and of no value. Many authors have supposed this cortical or wood-like substance to be real fossil wood; but this is an error. The masses of it are too large ever to have been trees, and their fibres run often to twenty, thirty, or forty feet diameter, in the same unbroken compages. It differs from trees also in this, that as they have been formed by successive additions of matter by vegetation, their whole bulk is composed of circular strata, if they may be so called, or additions of coats round a medulla or pith; but in this fossil wood, as some have supposed it to be, there is no pith or medulla, no addition of circular coats, but the same vast mass of it is continued to a vast length and breadth, in the manner of an earthy stratum, and is composed of thin laminæ, or plates laid flatwise, one over another. Were this substance really formed of the bodies of trees, we should also find in it that variety of fibres which the several parts of wood are known to consist of; but nothing of this kind appears; for we see the whole mass consist of absolutely the same shaped fibres; and there never was found, in any of this substance, the least resemblance of a knot or leaf, or the pedicle of a leaf, as might well be expected, had leaves ever grown from it. Phil. Trans. N° 248. p. 14.

The fossil wood, which is truly such, and has been once vegetable matter, whatever part of the world it is found in, agrees in the same general marks of distinction; and knots, and other evident proofs of its having been once vegetable, are found in all of it: but this *matrix* of amber, whether found in Prussia, Denmark, or elsewhere, is still of the same kind, and shews none of these characteristic marks of wood. However, notwithstanding all this, it is said, that on opening the ditches for the fortifications at Copenhagen, several large masses of amber were found, all of them adhering to the sides of large bodies of trees, which were black as ebony. The pieces are preserved in the cabinet of the king of Denmark in that place, and some of them weigh forty or fifty ounces. This is an additional circumstance to the common observation of something resembling wood, being always found where amber is, and deserves to be considered, as it tends to overthrow the present received system of amber being originally a mineral production.

Dr. Rothergill, in his Essay upon the Origin of Amber, maintains, that it is a vegetable resin, the product, perhaps, of the fir or pine kind; and that it is changed into its present form by a mineral acid. In proof of its resinous nature, he alleges its aspect, texture, and form: besides, the bodies inclosed in it are mostly animals of the flying kind, few reptiles, except such as ants, spiders, &c. which are found in trees, and scarcely ever any aquatics; and this could not happen in the sea, nor in the earth, but upon its surface. He apprehends, likewise, that this resin, with the trees which afforded it, were buried in the earth by the deluge, or some violent convulsion of the same kind: to which purpose he observes, that the substance of which the proper veins of amber consist, hath several genuine characteristics of wood still remaining; the texture of amber, which is fibrous, and, when dried, capable of swimming in water, and burning like other wood, shews, he says, what it hath been. Nor is the amber disposed in these veins in one continued stratum; but lumps of it are irregularly disseminated through the whole of the supposed woody mass. The change which this wood undergoes, is produced partly by time, and completed by the vitriolic mineral acid of the earth. Such an acid, it is argued, is present, wherever amber occurs in its proper *matrix*, and is sometimes found in the amber itself. The acid of the salt of amber is vitriolic; and common turpentine affords, by proper management with a vitriolic acid, a considerable portion of the same chemical principles that amber does; and those pieces of amber which have been found soft and imperfect, are nearly related to a vegetable resin. Phil. Trans. vol. xliii N° 472. p. 26, &c.

MATRIX is alſo applied figuratively for ſeveral things wherein there appears a kind of generation, and where certain things ſeem to acquire a new being, or at leaſt a new manner of being. Of which kind are the moulds wherein the printers types, or letters, are caſt; and thoſe uſed in ſtriking money and medals, in coining. See MATRICE.

MATRON, *matrona*, among the Romans, ſignified a married woman, and ſometimes alſo the mother of a family. There was, however, ſome difference between *matrona*, and *mater-familias*. Servius ſays, that ſome imagined the difference to lie in this, that *matrona* was a woman who had one child, and *mater-familias* one that had ſeveral. But others, particularly Aulus Gellius, take the name *matrona* to belong to a married woman, whether ſhe had any children or no; the hope and expectation of having them being enough to warrant the title of mother, *matrona*; and for this reaſon it is, that marriage is called *matrimony*. This opinion is ſupported by Nonius.

MATRON *of a hoſpital*. See HOSPITAL.

MATRONS, *jury of*, is a jury of twelve diſcreet women, directed by the judge to enquire into the fact, when a woman is capitally convicted, and pleads her pregnancy. This plea, though it cannot be made in ſtay of judgment, may be urged in reſpite of execution. If the jury bring in their verdict quick with child, execution ſhall be ſtaid generally till the next ſeſſion; and ſo from ſeſſion to ſeſſion, till either the woman is delivered, or proves, by the courſe of nature, not to have been with child at all. But if ſhe once hath had the benefit of this reprieve, and been delivered, and afterwards becomes pregnant again, ſhe ſhall not be entitled to the benefit of a farther reſpite for that cauſe; for ſhe may now be executed before the child is quick in the womb, and ſhall not, by her own incontinence, evade the ſentence of juſtice.

If a widow feigns herſelf with child, in order to exclude the next heir, and a ſuppoſititious birth is ſuſpected to be intended, then upon the writ *de ventre inſpiciendo*, a jury of women is to be impanelled to try the queſtion, whether with child or no?

MATRONALIA, feaſts of the Roman ladies, or rather *matrons*, celebrated on the calends of March, in honour of the god Mars.

Ovid mentions many reaſons for the inſtitution of this feaſt; but the principal ſeems to have been the peace concluded between the Romans and Sabines, by the mediation of the women. The women granted to their ſervants on this occaſion the ſame privileges which were granted to the ſlaves by their maſters in the SATURNALIA.

No men living in celibacy were allowed to aſſiſt at the feaſt.

MATROSSES, ſoldiers in the train of ARTILLERY, next below the gunners, and properly apprentices to them; their duty is to aſſiſt the gunners in traverſing, ſponging, loading, and firing of guns, &c. They carry fire-locks, and march along with the guns and ſtore-waggons, both as a guard, and to help in caſe of emergency.

MATT, in *Chemiſtry*, is a name given to an ore not perfectly deprived of its ſulphur, when fuſed: it is obtained in the firſt fuſion for the extraction of metal from ſome ores.

MATTADORE. See OMBRE.

MATTAGES, *in Zoology*, the Engliſh name of the largeſt ſpecies of the *lanius* or *butcher-bird*.

The word *mattages* is borrowed from the Savoyards, and ſignifies the murdering pye; and has been given it from its ſavage diſpoſition, and its reſemblance to the magpye in the ſhape of its tail. See BUTCHER-*bird*.

MATTS, on board a ſhip, a kind of broad, thick clouts, wove out of ſpun-yarn, or of a variety of ſtrands, or ſeparate parts of a ſmall rope, or of a number of rope-yarns twiſted into foxes; and uſed to preſerve the main and fore-yards from galling againſt the maſts at the ties, and at the gunnel of the ſhoe. They alſo ſerve to keep the clews of the ſail from galling there; as alſo to ſave the clews of the fore-ſail from doing ſo at the beak-head and bolſprit. The longeſt and ſtrongeſt ſort of theſe *matts* are called panches.

MATTER, *materia, body*, or an extended, ſolid, diviſible, moveable, and paſſive ſubſtance, the firſt principle of all natural things, from the various arrangements and combinations whereof all bodies are formed.

Ariſtotle makes three principles, *matter*, form, and privation; which laſt the Carteſians throw out of the number, and others the two laſt.

The properties of *matter* we are pretty well acquainted with, and can reaſon about its DIVISIBILITY, SOLIDITY, &c. but the ſubject wherein theſe properties reſide, or their ſubſtratum, is ſtill a myſtery. Ariſtotle ſpeaks very darkly on the ſubject, defining *matter* to be *nec quid, nec quantum, nec quale*, nor any certain determinate thing at all; which many of his followers interpret ſo as to believe, that *matter* does not at all exiſt. The CARTESIANS make the eſſence of *matter* to conſiſt in extenſion; arguing, that ſince the properties abovementioned are all that are eſſential to *matter*, ſome of them muſt conſtitute its eſſence; and, ſince extenſion is conceived prior to all the reſt, and is that without which none of the reſt can be conceived, extenſion is that which conſtitutes the eſſence of *matter*. But the concluſion here is unjuſt; for, on this principle, the exiſtence of *matter*, according to Dr. Clarke, would have the faireſt title to conſtitute its eſſence, the *exiſtere* being conceived prior to all properties, and even to extenſion. Since, then, the word extenſion appears to go farther, and to be more general, than *matter*, that impenetrable ſolidity, which is eſſential to all *matter*, and to *matter* alone, and from which all its properties manifeſtly flow, may, with more propriety, be called the *eſſence of matter*.

Again, if extenſion were the eſſence of *matter*, and ſo *matter* and ſpace the ſame thing, it would follow, that *matter* is infinite and eternal, that it is a neceſſary being, and could neither be created nor annihilated; which is abſurd. Beſides, it appears, both from the nature of gravity, the motions of comets, the vibrations of pendulums, &c. that ſpace is not *matter*; and therefore it is not extenſive, but ſolid, impenetrable extenſion, which has a power of reſiſting, that conſtitutes *matter*.

Many among the old philoſophers maintained the eternity of *matter*, out of which they ſuppoſed all things to be formed by the hands of nature; as being unable to conceive how any thing ſhould be formed out of nothing. Plato maintained, that *matter* had exiſted eternally, and concurred with God in the production of all things, as a paſſive principle, or a kind of collateral cauſe.

Matter and form, the two ſimple and original principles of all things, according to the ancients, compoſed ſome ſimple natures, which they called *elements*; out of the various combinations whereof all natural things were afterwards compoſed.

Dr. Woodward ſeems of an opinion not very unlike this, viz. that *matter* is originally and really very different, being at its firſt creation divided into ſeveral ranks, ſorts, or kinds, of corpuſcles, differing in ſubſtance, gravity, hardneſs, flexibility, figure, ſize, &c. from the various compoſitures and combinations of which, he thinks, ariſe all the varieties in bodies, as to colour, hardneſs, gravity, taſtes, &c. But Sir Iſaac Newton takes all thoſe differences to reſult from the various arrangements of the ſame *matter*; which he *judges* to be homogeneous and uniform in all bodies.

Beſides the properties of *matter* hitherto known, Sir Iſaac Newton has diſcovered a new one; viz. "That of attraction, or that every particle of *matter* has an attractive power, or a tendency towards every other particle; which power is ſtrongeſt in the point of contact, and ſuddenly decreaſes, inſomuch that it acts no more at the leaſt ſenſible diſtance; and, at a greater diſtance, is converted into a repellent force, whereby the parts fly from each other." On this principle of ATTRACTION, he accounts for the cohesion of the particles of bodies, which is otherwiſe inexplicable.

For he takes occaſion to obſerve, "That all bodies ſeem to be compounded of hard particles, even light itſelf, and all other the moſt volatile of fluids; inſomuch that hardneſs may be eſteemed a property of all uncompounded *matter*; at leaſt, the hardneſs of *matter* ſtands on as good a footing as that of its impenetrability; all the bodies we know of being either hard themſelves, or capable of being hardened. Now, if compound bodies be ſo hard, as we find ſome of them, and yet if they are very porous, and conſiſt of parts which are only laid together, the ſimple particles, which are void of pores, and were never yet divided, muſt be much harder. Now, ſuch hard particles being heaped together, can ſcarce touch one another in more than a few points; and therefore they muſt be ſeparable with much leſs force than is requiſite to break a ſolid particle, whoſe parts touch in all the ſpace, without any pores or interſtices to weaken their cohesion. How then ſhould ſuch very hard particles, only laid together, and touching only in a few points, ſtick together, and that ſo firmly as they do, without the aſſiſtance of ſomething that cauſes them to be attracted or preſſed towards each other?"

The ſame great author obſerves farther, "That the ſmalleſt particles may cohere by the ſtrongeſt attractions, and compoſe bigger particles of weaker virtue; and many of theſe may cohere, and compoſe ſtill bigger particles, whoſe virtue is ſtill weaker, and ſo on for divers ſucceſſions, until the progreſſion end in the biggeſt particles; on which the operations in chemiſtry, and the colours of natural bodies, depend, and,

"which,

" which, by cohering, compose bodies of a sensible magnitude. If the body is compact, and bends or yields inward to pression, without any sliding of its parts, it is *hard*, and *elastic*; returning to its figure with a force arising from the mutual attraction of its parts. If the parts slide from one another, the body is *malleable* or soft. If they slip easily, and are of a fit size to be agitated by heat, and the natural heat is great enough to keep them in agitation, the body is *fluid*; and, if it be apt to stick to things, it is *humid*. And the drops of every fluid affect a round figure by the mutual attraction of their parts, as the globe of the earth and sea affects a round figure, by the mutual attraction of gravity of its parts."

Again, " Since metals, dissolved in acids, attract but a small quantity of the acid, their attractive force reaches but to a small distance. Now, as in algebra, where affirmative quantities cease, there negative ones begin; so in mechanics, where attraction ceases, there a repulsive virtue must succeed. That there really is such a virtue, seems to follow from the reflexions and inflexions of the rays of light; the rays being repelled by bodies in both these cases, without the immediate contact of the reflecting or inflecting body. The same thing seems also to follow from the emition of light; a ray, as soon as shaken off from a shining body by the vibrating motion of the parts of the body, and got beyond the reach of attraction, being driven away with exceeding great velocity: for that force, which is sufficient to turn it back in reflexion, may be sufficient to emit it. It seems also to follow from the production of air and vapour; the particles, when they are shaken off from the body by heat or fermentation, so soon as they are beyond the reach of the attraction of the body, receding from it, and also from one another, with great strength, and keeping at a distance, so as sometimes to take up above a million of times more space than they did before in the form of a dense body; which vast contraction and expansion seems unintelligible, by feigning the particles of air to be springy and ramous, or rolled up like hoops, or by any other means than a repulsive power. The particles of fluids, which do not cohere too strongly, and are of such a smallness, as renders them most susceptible of those agitations which keep liquors in a fluor, are more easily separated and rarefied into vapour, i. e. in the language of the chemists, they are *volatile*; rarefying with an easy heat, and condensing again with cold. But those which are grosser, and so are less susceptible of agitation, or which cohere by a stronger attraction, are not separated without a stronger heat, or perhaps not without fermentation. And these last are the bodies which chemists called *fixed*; and yet these, being rarefied by fermentation, become true permanent air; those particles receding with the greatest force, and being most difficultly brought together, which, upon contact, cohere the most strongly. And because the particles of permanent air are grosser, and arise from denser substances than those of vapours; thence it is, that true air is more ponderous than vapour; and that a moist atmosphere is lighter than a dry one, quantity for quantity. From the same repelling power it seems to be, that flies walk upon the water without wetting their feet; and that the object glasses of long telescopes lie upon one another without touching; and that dry powders are difficultly made to touch one another so as to stick together, unless by melting them, or wetting them with water, which, by exhaling, may bring them together; and that two polished marbles, which by immediate contact stick together, are yet difficultly brought so close together as to stick."

He farther observes, " That, all things considered, it seems probable, God, in the beginning, formed *matter* in solid, massy, hard, impenetrable, moveable particles, of such sizes, figures, and with such other properties, and in such proportion to space, as most conduced to the end for which he formed them; and that these primitive particles, being solid, are incomparably harder than any porous bodies compounded of them; even so very hard, as never to wear, and break in pieces: no ordinary power being able to divide what God himself made one in the first creation. While the particles continue entire, they may compose bodies of one and the same nature and texture in all ages; but should they wear away, or break in pieces, the nature of things depending on them would be changed. Water and earth, composed of old worn particles, and fragments of particles, would not be of the same nature and texture now with water and earth composed of entire particles in the beginning. And therefore, that nature may be lasting, the changes of corporeal things are to be placed only in the various separations, and new associations and motions, of these permanent particles; compound bodies being apt to break not in the midst of solid particles, but where those particles are laid together, and touch in a few points."

It seems farther, " That these particles have not only a *vis inertiæ*, accompanied with such passive laws of motion as naturally result from that force, but also that they are moved by certain active principles, such as is that of gravity, and that which causeth fermentation, and the cohesion of bodies. These principles are to be considered not as occult qualities, supposed to result from the specific forms of things, but as general laws of nature, by which the things themselves are formed; their truth appearing to us by phænomena, though their causes are not yet discovered."

Hobbes, Spinoza, &c. maintain all the beings in the universe to be *material*, and their differences to arise from their different modifications, motions, &c. Thus *matter* extremely subtile, and in a brisk motion, they conceive, may think; and so they exclude all spirits out of the world. See Hobbism and Spinozism.

Dr. Berkeley, on the contrary, argues against the existence of *matter* itself; and endeavours to prove, that it is a mere *ens rationis*, and has no existence out of the mind. See Abstraction, Body, and Existence.

Some late philosophers have advanced a new hypothesis concerning the nature and essential properties of *matter*. The first person who suggested, or at least published an account of this hypothesis, was M. Boscovich, in his Theoria Philosophiæ Naturalis. Venice, 1763. He supposes that *matter* is not impenetrable, as before him it had been universally taken for granted; but that it consists of physical points only, endued with powers of attraction and repulsion, taking place at different distances, that is, surrounded with various spheres of attraction and repulsion; in the same manner as solid *matter* is generally supposed to be. Provided, therefore, that any body move with a sufficient degree of velocity, or have sufficient momentum to overcome any power of repulsion that it may meet with, it will find no difficulty in making its way through any body whatever; for nothing will interfere, or penetrate another, but powers, such as we know do in fact exist in the same place, and counterbalance and over-rule one another; a circumstance which never had the appearance of a contradiction, or even of a difficulty. If the momentum of such a body in motion be sufficiently great, M. Boscovich demonstrates, that the particles of any body through which it passes will not even be moved out of their place by it. With a degree of velocity something less than this, they will be considerably agitated, and ignition might perhaps be the consequence; though the progress of the body in motion would not be sensibly interrupted; and with a still less momentum it might not pass at all. This theory M. Boscovich has taken great pains to illustrate and confirm; shewing, that it is by no means inconsistent with any thing that we know concerning the laws of mechanics, or our discoveries in natural philosophy; and that a great variety of phenomena, particularly those which relate to Light, admit of a much easier solution upon this hypothesis than upon any other. The most obvious difficulty, says Dr. Priestley, and indeed the only one that attends this hypothesis, as it supposes the mutual penetrability of *matter*, arises from the difficulty we meet with in attempting to force two bodies into the same place. But it is demonstrable, that the first obstruction arises from no actual contact of *matter*, but from mere powers of repulsion. This difficulty we can overcome; and having got within one sphere of repulsion, we fancy that we are now impeded by the solid *matter* itself. But the very same is the apprehension of the generality of mankind with respect to the first obstruction. Why, therefore, says he, may not the next resistance be only another sphere of repulsion, which may only acquire a greater force than we can apply to overcome it, without disordering the arrangement of the constituent particles; but which may be overcome by a body moving with the amazing velocity of light.

This scheme of the mutual penetration of *matter* first occurred to Mr. Michell, independently of any communication with M. Boscovich, on reading Baxter on the Immateriality of the Soul. He found that this author's idea of *matter* was, that it consisted, as it were, of bricks cemented together by an immaterial mortar. These bricks, if he would be consistent in his reasoning, were again composed of less bricks, cemented like wise by an immaterial mortar, and so on *ad infinitum*. This putting Mr. Michell upon the consideration of the appearances of nature, he began to perceive that the bricks were so covered with this immaterial mortar, that, if they had any existence at all, it could not possibly be perceived; every effect being produced at least in nine instances in ten certainly,

tainly, and probably in the tenth alſo, by this immaterial, ſpiritual, and penetrable mortar. Mr. Michell, finding it neceſſary, in order to ſolve the appearances of nature, to admit of extended and penetrable immaterial ſubſtance, if he maintained the impenetrability of *matter*; and obſerving farther, that all we perceive by contact, &c. is this penetrable immaterial ſubſtance, and not the impenetrable one, began to think, that he might as well admit of penetrable material, as penetrable immaterial ſubſtance; eſpecially as we know nothing more of the nature of ſubſtance than that it is ſomething which ſupports properties; which properties may be whatever we pleaſe, provided they be not inconſiſtent with each other, that is, do not imply the abſence of each other. This by no means ſeemed to be the caſe, in ſuppoſing two ſubſtances to be in the ſame place at the ſame time, without excluding each other; the objection to which is only derived from the reſiſtance we meet with to the touch, and is a prejudice that has taken its riſe from that circumſtance. Dr. Prieſtley obſerves, that if he were to make any alteration in this hypotheſis, it would be to ſuppoſe the force of the ſphere of repulſion next to any of the indiviſible points, which conſtitute what we call ſolid bodies, not to be abſolutely infinite, but ſuch as may be overcome by the momentum of light. If, however, we conſider that Mr. Boſcovich makes this neareſt power of repulſion not to extend to any real ſpace, but to be confined to the indiviſible point itſelf, it may appear to be ſufficient for the purpoſe. Such is the account which Dr. Prieſtley, a zealous and able advocate for this hypotheſis, has given of it, in his Hiſtory and preſent State of Diſcoveries relating to Light, &c. p. 390, &c.

In conformity to this hypotheſis, Dr. Prieſtley maintains, that *matter* is not that inert ſubſtance that it has been ſuppoſed to be; that powers of attraction or repulſion are neceſſary to its very being, and that no part of it appears to be impenetrable to other parts. Accordingly, he defines *matter* to be a ſubſtance, poſſeſſed of the property of extenſion, and of powers of attraction or repulſion, which are not diſtinct from *matter*, and foreign to it, as it has been generally imagined, but abſolutely eſſential to its very nature and being: ſo that when bodies are diveſted of theſe powers, they become nothing at all. However, though he ſuppoſes that theſe powers are eſſential to the being of *matter*, inſomuch that it cannot exiſt without them as a material ſubſtance at all, he by no means maintains that they are ſelf-exiſtent in it; but that from whatever ſource theſe powers are derived, or by whatever being they are communicated, *matter* cannot exiſt without them; and if that ſuperior power or being withdraw its influence, the ſubſtance itſelf neceſſarily ceaſes to exiſt, or is annihilated. Whatever ſolidity any body has, it is poſſeſſed of only in conſequence of being endued with certain powers, and together with this cauſe, ſolidity, being no more than an effect, muſt ceaſe. Dr. Prieſtley, in another place, has given a ſomewhat different account of *matter*; according to which it is only a number of centers of attraction and repulſion; or more properly of centers, not diviſible, to which divine agency is directed; and as ſenſation and thought are not incompatible with theſe powers, ſolidity, or impenetrability, and conſequently a *vis inertiæ*, only, having been thought repugnant to them, he maintains, that we have no reaſon to ſuppoſe that there are in man two ſubſtances abſolutely diſtinct from each other. Diſquiſitions on *Matter* and Spirit, 1777, paſſim. See SOUL.

Dr. Price, in a correſpondence with Dr. Prieſtley, publiſhed under the title of a Free Diſcuſſion of the Doctrines of Materialiſm and Philoſophical Neceſſity, 1778, has ſuggeſted a variety of unanſwerable objections againſt this hypotheſis of the penetrability of *matter*, and againſt the concluſions which are drawn from it. The *vis inertiæ* of *matter*, he ſays, is the foundation of all that is demonſtrated by natural philoſophers concerning the laws of the colliſion of bodies. This, in particular, is the foundation of Sir Iſaac Newton's philoſophy, and eſpecially of his three laws of motion. Solid *matter* has the power of acting on other *matter* by impulſe; but unſolid *matter* cannot act at all by impulſe; and this is the only way in which it is capable of acting, by any action that is properly its own. If it be ſaid, that one particle of *matter* can act upon another without contact and impulſe, or that *matter* can, by its own proper agency, attract or repel other *matter* which is at a diſtance from it, then a maxim hitherto univerſally received muſt be falſe, that "nothing can act where it is not." Sir I. Newton, in his Letters to Dr. Bentley, calls the notion, that *matter* poſſeſſes an innate power of attraction, or that it can act upon *matter* at a diſtance, and attract and repel by its own agency, an abſurdity into which, he thought, no one could poſſibly fall. And in another place he expreſſly diſclaims the notion of innate gravity, and has taken pains to ſhew that he did not take it to be an eſſential property of bodies. By the ſame kind of reaſoning purſued, it muſt appear, that *matter* has not the power of attracting and repelling; that this power is the power of ſome foreign cauſe, acting upon *matter* according to fixed laws; and that, conſequently, attraction and repulſion, not being actions, much leſs inherent qualities of *matter*, as ſuch, it ought not to be deemed by them. And if *matter* has no other property, as Dr. Prieſtley aſſerts, than the power of attracting and repelling, it muſt be a non-entity; becauſe this is a property that cannot belong to it. Beſides, all power is the power of ſomething; and yet if *matter* is nothing but this power, it muſt be the power of nothing; and the very idea of it is a contradiction. If *matter* is not ſolid extenſion, what can it be more than mere extenſion? Farther, *matter* that is not ſolid is the ſame with pure; it cannot, therefore, poſſeſs what natural philoſophers mean by the momentum or force of bodies, which is always in proportion to the quantity of *matter* in bodies, void of pore. Momentum is the cauſe of reſiſtance, and not *vice verſâ*. Moreover, within the ſphere of repulſion, the attraction of cohеſion takes place; and this is the power which, according to Dr. Prieſtley, unites the parts of *matter*, and gives it exiſtence. But, ſince *matter* is penetrable, will not this attraction drive all the parts of it into one another, and cauſe them to coaleſce into nothing? This effect muſt follow, unleſs there exiſts, beyond the ſphere of attraction, and nearer to *matter*, a ſecond ſphere of repulſion, which again prevents contact. Thus it appears evident, that if a power of attracting acts, it muſt contract itſelf into nothing; and that if a power of repulſion acts, it muſt diſſipate itſelf into nothing. For a farther account of the arguments pro and con on this ſubject, we muſt refer to the work already cited.

MATTER, *abſtract*. See ABSTRACT.

MATTER, *ſubtile*. See MATERIA *ſubtilis*.

MATTER, *quantity of*. See QUANTITY.

MATTER *of fact* ſignifies a truth to be proved, though not by any record: by which it ſtands diſtinguiſhed from

MATTER *of record*, which is that which may be proved by ſome record.

If a man be ſued to an exigent during the time he was in the king's wars, this is *matter in deed*, and not *matter of record*; and therefore he muſt allege this for himſelf, muſt come before the ſcire facias, or execution be awarded againſt him; for, after that, nothing will ſerve but *matter of record*; that is, ſome error upon the proceſs appearing upon record.

MATTER, *foreign*. See FOREIGN.

MATTHEW, or *Goſpel of St. Matthew*, 2 canonical book of the New Teſtament. St. *Matthew* is ſaid by many to have wrote his Goſpel in Judea, at the requeſt of thoſe he had converted, and it is thought by ſome, as Baronius, Grotius, Veſſius, Jones, Weſtein, &c. that he began it in the year 41, eight years after Chriſt's reſurrection. But according to others, as Mill, Baſnage, Dr. Lardner, &c. who follow the teſtimony of Irenæus, this goſpel was wrote in the time of Nero, about thirty years after our Savior's aſcenſion, or about the year 64 or 65 of the vulgar epoch. It was written, according to the teſtimony of moſt of the ancients, as Papias, A. D. 116, Irenæus in 178, Origen in 230, Euſebius in 315, Athanaſius, Cyril of Jeruſalem, Epiphanius, Gregory Nazianzen, Theodore Moplueſtia, Jerome, Chryſoſtom, &c. in the Hebrew or Syriac language, which was then common in Judea; but the Greek verſion of it, which now paſſes for the original, is ſaid to be as old as the apoſtolical times. However, many learned moderns, as Erafmus, Calvin, Le Clerc, &c. are of opinion, that this goſpel was firſt wrote in Greek, which was much uſed at that time throughout the whole Roman empire, and particularly in Judea; and it is alleged, that Papias, who firſt advanced this opinion, was a weak and credulous man. Le Clerc, Jones, Baſnage, Lardner, &c. are of this opinion. Dr. Lardner obſerves on this point, that if St. *Matthew* did not write till about thirty years after our Lord's aſcenſion, which he thinks moſt probable, he would uſe the Greek language; but if he wrote his goſpel within the ſpace of eight years after Chriſt's aſcenſion, it is moſt likely that he wrote in the Hebrew. He adds farther, that there was very early a Greek goſpel of St. *Matthew*, cited and referred to by Clement of Rome, Ignatius, Polycarp, Juſtin Martyr, and others; that many of the ancients do not ſeem to have fully believed that *Matthew* wrote in Hebrew, becauſe they have ſhewn very little regard to the Hebrew edition of it; that there are not in our Greek goſpel of St. *Matthew* any marks of a tranſlation; that there is no where any probable account who tranſlated this goſpel into Greek;

and besides, as the Greek gospel was translated into Hebrew in very early days of Christianity, many not examining it particularly, nor indeed being able to do it, for want of understanding the language, might imagine, that it was first writ in Hebrew. Hence, according to Dr. Lardner, sprung the opinion, that *Matthew* published his gospel at Jerusalem, or in Judæa, for the Jewish believers, and at their request, before he went abroad to other people: whereas he apprehends, that this gospel, as well as the others, were writ and intended for believers of all nations; and that the Nazarene gospel was St. *Matthew's* gospel, translated from Greek, with the addition of some other things, taken from the other gospels, and from tradition. Allowing the date of this gospel already assigned, he cannot conceive the reason why *Matthew* should write in Hebrew any more than any of the other evangelists; for it may be reckoned highly probable, or even certain, that he understood Greek, before he was called by Christ to be an apostle. Whilst a publican, he would have frequent occasions both to write and speak Greek, and could not discharge his office, without understanding that language. Lardner's Credibility, &c. vol. xv. chap. 5.

St. MATTHEW's *day*, is a festival observed on the twenty-first of September.

MATTHIOLA, in *Botany*, a genus of the *pentandria monogynia* class, the characters of which are these: the cup is a cylindric perianthium, is very short, erect, and undivided, and remains after the flower is fallen; the flower is monopetalous, and consists of a very long tube, which dilates, by degrees, into a large and wide mouth, with a smooth or undivided edge; the stamina are five pointed filaments, shorter than the flower; the apices are simple; the germen of the pistil is globose, and is placed beneath the cup; the style is very slender, and of the length of the cup; the stigma is large and obtuse; the fruit is a drupe of a globose figure, containing only one cell, and crowned with the cup; the seed is a globose nut or stone, containing a kernel of the same globose form.

MATTINS, from the Italian *mattino*, or the French *matin*, *morning*, the first part in the daily service of the Romish church.

Mattins are sometimes held early in the morning, sometimes at midnight, and sometimes the evening before; and infirm people, even in monasteries, are dispensed from attending *mattins*.

MATTKEM, in *Ornithology*, a common name in Germany for the MATKNELTZEL.

MATUITUI, in *Ornithology*, the name of a Brasilian bird, of the tardus or thrush kind, and of the bigness of the common starling. See CURICACA.

MATULAM.—*Hydrops ad* MATULAM. See HYDROPS.

MATURANTIA, in *Medicine*, &c. *ripeners*; or such things as promote maturation. See SUPPURATION.

MATURAQUE, in *Ichthyology*, the name of an American fish, of the harengiform kind, and having only one short fin on the back. It seldom grows to more than four inches long, and is somewhat flattish, but not very broad; its head is very broad, and covered with a shelly crust; it is caught in lakes, not in rivers, and is a well tasted fish.

MATURATION *of fruit*, *in Gardening*. See CAPRIFICATION, FORCING, and HOT-*beds*.

MATURATION, in *Pharmacy*, a preparation of fruits, or other simples, gathered before their maturity, to fit them to be eaten, or for other uses. See FRUIT, &c.

MAUCUACO, in *Zoology*, is made a distinct genus of animals, with six cutting teeth, and two canine teeth in each jaw, a sharp pointed visage like a fox, and feet formed like a hand. This genus comprehends several species of the LEMUR, according to the Linnæan system. See LORIS, MONGOOZ, &c.

MAUDIHOCA, the cassada, or the poisonous root of which bread is made in many parts of the West Indies.

MAUDLIN, in *Botany*. See YARROW, and AGERATUM.

MAVIS, in *Zoology*, the common name of the song thrush, or THROSTLE.

MAUNCH, the figure of an ancient sleeve of a coat, so called by the heraldry, and is borne in many gentlemen's escutcheons; as in the earl of Huntingdon's. See *Tab. Heraldry fig.* 40.

MAUND, in our *Old Writers*, a kind of great basket or hamper, containing eight bales, or two fats: it is commonly a quantity of eight bales of unbound books, each bale having one thousand pounds weight. Book of Rates, p. 3.

MAUNDY, or MAUNDEY *Thursday*, *Dies* MANDATI, the Thursday before Easter; so called from the French *manche*, i. e. *sportula*; it being a custom on that day to give a largess or bounty to certain poor men, whose feet the king formerly washed, as a mark of humility, and in obedience to the command of Christ.

St. MAUR, *congregation of*, in *Ecclesiastical History*, a famous society of BENEDICTINS, which was founded in the year 1620, by the express order of Gregory XV. and enriched by Urban VIII. in 1627, with several donations and privileges. This society has been distinguished by the great number of excellent rules and institutions that are observed in it, and by the regular lives and learned labours of its members. Those who have any acquaintance with the history and progress of learning in Europe, well know what signal advantages the republic of letters has derived from the establishment of this famous congregation, whose numerous and admirable productions have cast a great light upon all the branches of philology and belles lettres, and whose researches have taken in the whole circle of sciences, philosophy excepted. These Benedictins still maintain their literary fame, by the frequent publication of laborious and learned productions in all the various branches of sacred and profane literature.

MAUROCENIA, in *Botany*. See *Hottentot* CHERRY.

MAUROUSE, the name of a creature of the deer kind, mentioned by Josselyn. It seems to be the same with the *dama Virginiana* of Mr. Ray, one of which creatures was, in his time, kept alive in St. James's park.

This is not certain, however; for Josselyn's description is very imperfect; he only says it is like the moose-deer, but is small, and has small horns.

MAUSOLEUM, a magnificent tomb, or funeral MONUMENT, decorated with architecture and sculpture, and inscribed with an epitaph; erected in honour of some emperor, prince, or other illustrious person.

The word comes from *Mausolus*, the name of a king of Caria, to whom Artemisia, his widow, erected a most stately monument, that has since been numbered among the seven wonders of the world; calling it, from his name, *Mausoleum*. It was sixty three feet long, almost four hundred and eleven feet in compass, and about thirty-five feet high, surrounded with thirty-six columns, that were beautified in a wonderful manner. Pliny has described it, lib. xxxvi. cap. 5. Afterwards the same name was given to all costly monuments. Thus the stately monument was called, which Augustus built, during his sixth consulship, between the Flaminia via and the Tiber, to be a burial place for him and his family, and which Strabo has described in his fifth book. It is also the name which Florus, lib. iv. cap. 11. gives to the monuments of the kings of Egypt, wherein Cleopatra shut herself up, and put herself to death. Many authorities testify, that the Romans gave this name to those sepulchres whose structure was magnificent.

MAUSOLEUM is also used to signify the decoration of a fictitious tomb, or catafalcha, in a funeral pomp.

MAW. See ABOMASUS.

MAW, *sea*. See SEA-MALL.

MAXILLÆ, in *Anatomy*, the jaws; or those parts of an animal, wherein the teeth are set, and which serve for masticating the food.

The *maxillæ* are two in number, and are denominated, from their situation, *superior*, and *inferior*.

MAXILLA *superior*, or the upper jaw, is immoveable in man, and all other animals we know of; excepting parrots, crocodiles, and the acus vulgaris, or gar-fish. Vide Ray Synopf. Pisc. p. 109.

The upper jaw comprehends not only the two large bones named *ossa maxillaria*, from *maxilla*, by which this portion of the face is expressed, but likewise the two *ossa* MALARUM, the two *ossa* UNGUIS, or lachrymalia, the two *ossa* NASI, the two *ossa* PALATI, the two *ossa conchoidea*, or lower shells of the NOSE, and one single bone, called VOMER. All these amount to thirteen in number. In this jaw are alveoli, or sockets, for sixteen teeth. See *Tab. Anat. (Osteol.) fig.* 1. *lit. d.*

MAXILLA *inferior*, or the lower jaw, only consists of two bones, which unite in the middle of the chin, by the intervention of a cartilage, which hardens as the child grows; and at length, about the age of seven years, becoming bony, joins the two bones into a continued one, resembling the Greek ω. See *Tab. Anat. (Osteol.) fig.* 1. *lit. e.*

It consists of two tables, betwixt which is a spongy substance, in children medullary. The fore-part is shallow, just sufficient to afford sockets for sixteen teeth; it has two processes, the *coronæ* and *condyloides*; four holes or foramina for the passage of vessels, and five pair of proper muscles, viz. the crotaphytes or temporal, the masseter, biventer or digastricus, pterygoideus internus, and pterygoideus externus. See each in its place.

The lower jaw is connected with the ossa temporum, by a very singular kind of articulation, partaking of the nature both of a ginglymus and arthrodia, and termed by Winslow amphidiarthrosis. Its principal motions are upward and downward, and in all the different degrees thereof we can thrust it forward, pull it backward, and turn

turn it to either side; and in the same manner, in any degree of motion forward, backward, or laterally, we can raise or depress it. The mechanism of this articulation of its motions depend on a cartilage.

MAXILLÆ *quartus*, in *Anatomy*, a name given by Vesalius, and some others, to one of the muscles of the lower jaw, commonly known by the name of the DIGASTRICUS, and called by Albinus, BIVENTER *maxillæ inferioris*.

MAXILLAM *attollens tertius*, in *Anatomy*, a name given by Riolanus, and some others, to a muscle of the face, more generally known by the name of MASSETER.

MAXILLARY *bones*, *maxillaria ossa*, or great bones of the upper jaw, are two in number, situated one on each side, in the anterior and middle part of the face; their conformation is very irregular, and they are of very considerable extent. Anatomists generally divide them into the external and internal sides. By the external side they mean all that appears in an entire skull, without taking in the arch of the palate, and by the internal side, that which makes part of the arch of the palate, and all that is turned to the *septum narium*. The separation of this bone, by a small transverse suture behind the *foramen incisivum*, is seldom found but in young subjects, before the ossification is completed. The *maxillary* bone is almost all compact, and without diploe, except in the alveolary arch, and at the point of the orbitary apophysis.

The *ossa maxillaria* are connected with the *os frontis*, *os ethmoides*, *os sphenoides*, *ossa unguis*, *ossa malarum*, *ossa nasi*, *ossa palati*, *vomer*, *cornua narium inferiora*, and with one another. They assist in forming the organ of mastication, the arch of the palate, the cheeks, the orbits, the nose, &c. Winslow's Anatomy, p. 32, seq. See JAW.

MAXILLARY *gland*, MAXILLARIS *glandula*, a considerable gland of the conglomerate kind, situate on the inside, under the lower jaw-bone, near the musculus digastricus. It discharges itself by several branches of ducts, which form one trunk, that passes under the mylohyoideus, and meets with the *maxillary gland* of the other side within the fore-teeth of the lower jaw, having distinct orifices with a papilla on each side the frænum linguæ. See GLAND and MOUTH.

MAXILLARY *muscles*, in fish, two large muscles placed under the lower jaw, and serving to move it; these, with the two hypophthalmic muscles, which are placed under the eyes, are the four cephalic muscles of fishes, according to authors.

MAXIM denotes an established proposition or principle.

In which sense it amounts to much the same with AXIOM. *Maxims* are a kind of propositions, which have passed for principles of science; and which, being self-evident, have been by some supposed innate.

A *maxim* in law is said to be a proposition, of all men confessed and granted without argument or discourse. *Maxims* of the law are holden for law; and all other cases that may be applied to them, shall be taken for granted.* 1 Inst. 11. 67. 4 Rep. The *maxims* in our law-books, which are many and various, are such as the following, viz. It is a *maxim*, that land shall descend from the father to the son, &c. That if a man have two sons by divers venters, and the one purchase lands and die without issue, the other shall never be his heir, &c. That as no estate can be vested in the king without matter of record, so none can be divested out of him but by matter of record. That an obligation, or matter in writing cannot be dissolved by an agreement by word, without writing. Co. Litt. 11. 141. See LAW.

MAXIMUM, in *Mathematics*, denotes the greatest quantity attainable in any given case.

By which it stands opposed to MINIMUM.

Methodus de MAXIMIS *&* MINIMIS, a method so called, in use among mathematicians, whereby they arrive at the greatest or least possible quantity attainable in any case.

If the semiordinates of any curve continually increase or decrease to some certain term, which once passed they begin again to decrease or increase, the method whereby their *maxima & minima*, i. e. their greatest and least states are determined, is called the method *de maximis & minimis*; which, it is true, may be used to determine other quantities that increase or decrease to any certain term; but then they must always be represented by the semiordinates of curves.

If a flowing quantity in an equation be proposed to be determined to any extreme value; the rule is: having put the equation into fluxions, let the fluxion of that quantity (whose extreme value is sought) be supposed $=0$; by this means, all those members of the equation, in which it is found, will vanish, and the remaining ones will give the determination of the *maximum* or *minimum* desired.

The reason of the rule is, that every *maximum* or *minimum* is, in its own nature, a stable quantity, because at that term where a quantity becomes a *maximum* or *minimum*, it can neither be increasing nor decreasing: to determine therefore any flowing quantity to a *maximum* or *minimum*, is to make it (instead of a flowing) a permanent one; but the fluxion of a permanent quantity is equal to nothing. This we shall illustrate by the following examples.

I. To *determine the greatest or least applicate in an algebraic curve.* Since, in curves that have a *maximum* and a *minimum*, the tangent T M (*Tab. Analyt. fig.* 4. and *fig.* 26.) degenerates at length into D E, and becomes parallel to the axis, and so the perpendicular M H coincides with the greatest or least applicate C G; in the case of *maximum* and *minimum*, the subtangent T P becomes infinite, and the subnormal P H equal to nothing: but $PH=\frac{\dot{y}\dot{x}}{\dot{x}}$. If then $\frac{\dot{y}\dot{x}}{\dot{x}}=0$, we shall find $\dot{y}=0$; and because of $PT=\frac{\dot{y}x}{\dot{y}}=\infty$ (the note of infinity) $\dot{x}=\infty$. It is possible for the tangent H G (*fig.* 5.) to lie directly against the semiordinate G C; in which case, the subtangent P T is equal to nothing, and the subnormal P H is infinite. But $PT=\frac{y\dot{x}}{\dot{y}}=0$; therefore if $\frac{x\dot{x}}{\dot{y}}=0$, we shall have $\dot{x}=0$; or because $PH=\frac{\dot{y}\dot{x}}{\dot{x}}=\infty$, we find $\dot{y}=\infty$; both $\dot{x}$ and $\dot{y}$ being, in respect of $\dot{y}$, infinitesimals. From the equation of the curve therefore we are to find the value of $\dot{y}$, which is to be made equal either to nothing, or to infinity, that we may have the value of the abscis, to which the greatest applicate is co-ordinate.

II. To *cut a right line* A B (*fig.* 6.) *in such a manner in* D, *that the rectangle* A D *and* D B *shall be the greatest that can possibly be thus contributed.* Let A B $=a$, A D $=x$; then will D B $=a-x$; consequently A D $\times$ D B $=ax-xx$, some *maximum*; and hence its fluxion will be equal to nothing, as being conceived at a circle to which

$$\frac{a\dot{x}-x\dot{x}=\dot{y}}{}$$

Wherefore $a\dot{x}-2x\dot{x}=\dot{y}=0$

$$\frac{a-2x=0}{}$$

$$\frac{\frac{1}{2}a=x}{}$$

The line A B therefore is to be cut into two equal parts; and the square is the greatest of all rectangles, whose altitudes and bases, taken together, are equal to each other.

III. To *find the fraction which shall exceed its cube by the greatest quantity possible.* Let x denote a variable quantity, expressing number in general; then the excess of x above x^3 being universally represented by $x-x^3$, we shall have the fluxion of this quantity, or $\dot{x}-3x^2\dot{x}=0$; and therefore, $x=\sqrt{\frac{1}{3}}$ the fraction required.

IV. *To determine the greatest rectangle that can be inscribed in a given triangle.* Let the base A C of the triangle (*Tab.* III. *Analyt. fig.* 66.) $=b$, and its altitude B D $=a$; and let the altitude B S of the inscribed rectangle $=x$, considered as variable, be x: then, because of the parallel lines A C, $x\,x$, it will be B D (a) : A C (b) :: D S $(a-x)$: $\frac{ba-bx}{a}=x\,z$: whence the area of the rectangle, or $a\,c\times$ B S will be $=\frac{bax-bx^2}{a}$; whose fluxion $\frac{ba\dot{x}-2bx\dot{x}}{a}$ being $=0$, we shall have $x=\frac{1}{2}a$: and, therefore, the greatest inscribed rectangle is that whose altitude is just half the altitude of the triangle.

V. To *determine the greatest cylinder*, d g, *that can be inscribed in a given cone* A D B. (*Tab.* III. *Analyt. fig.* 67.) Let $a=$ B C, the altitude of the cone, $b=$ A D, the diameter of its base; $x=fg$ (de) the diameter of the cylinder, considered as variable; $p=\frac{3.14159}{4}$ &c. the area of the circle whose diameter is unity: then the areas of circles being to one another as the squares of their diameters, we have, $1^2 : x^2 :: p : px^2$ the area of the circle $fxgx$. Moreover, from the similarity of the triangles A B C and A df, we have $\frac{1}{2}b$ (A C) : a (B C) :: $\frac{1}{2}b-\frac{1}{2}x$ (A d) : $df=\frac{ab-ax}{b}$; which multiplied by the area px^2 gives $\frac{pabx^2-pax^3}{b}$ for the solid content of the cylinder; which being a *maximum*, its fluxion $\frac{2pabx\dot{x}-3pax^2\dot{x}}{b}$ must be $=0$; consequently $x=\frac{2b}{3}$ and $d\,f=\frac{a}{3}$: whence it appears that the inscribed

cylinder

cylinder will be the greatest possible, when the altitude thereof is just $\frac{1}{3}$ of the altitude of the whole cone.

VI. *To find the greatest cone that can be inscribed in a given sphere.* Let A D (*fig.* 68.) the diameter of the sphere be $= a$; 78539, &c. the area of a circle, whose diameter is 1, be $= r$; and A C, the altitude of the cone, $= x$; then C D $= a - x$. Then by 35 Euc. 3. A C × C D $=$ C B^2; i. e. $ax - x^2 = a^2 - 2ax + x^2 =$ C B^2; therefore (because the square of the diameter is four times the square of the radius) by 2 Euc. 12. $4arx - 4rx^2 =$ the area of the cone's base; which, by 10 Euc. 12. drawn into $\frac{1}{3}x$ is $\frac{1}{3}arx^2 - \frac{1}{3}rx^3 =$ the cone's solidity, a *maximum*: therefore, since all the affirmative powers of a quantity that is a *maximum* or *minimum*, as well as the sum, remainder, product, or quotient, arising from the *maximum* or *minimum*, and any invariable quantity, are *maxima* or *minima* likewise, $ax^2 - x^3$ a *maximum*: and its fluxion $2axx - 3x^2x = 0$; which divided by xx gives $2a - 3x = 0$, and $3x = 2a$, and $x = \frac{2}{3}a$: so that the cone will be a *maximum*, when its altitude is $\frac{2}{3}$ of the sphere's diameter. The reader may find a variety of other examples in Simpson's Fluxions, vol. I. sect. 2. and Rowe's Fluxions, chap. 4.

The fluxion of the base of a curve, or its abscissa being given, when the fluxion of the ordinate vanishes, the tangent becomes parallel to the base, and the ordinate, most commonly, is a *maximum* or *minimum*, according to the rule given by authors on this subject, and mentioned in the preceding part of this article. But it is to be observed, that if the second fluxion of the ordinate vanish at the same time, and the third fluxion be real, this rule does not hold; for the ordinate is, in that case, neither a *maximum* nor a *minimum*. If the first, second, and third fluxions vanish, and the fourth fluxion be real, the ordinate is a *maximum* or *minimum*. The general rule given by Mr. Maclaurin, is, that when the first fluxion of the ordinate, with its fluxions of any subsequent successive orders, vanish, and the number of all these fluxions that vanish is odd, then the ordinate is a *maximum* or *minimum*, according as the fluxion of the next order to these is negative or positive. But if the number of all the fluxions of the ordinate, of the first and subsequent successive orders that vanish, be an even number, the ordinate is then neither a *maximum* nor a *minimum*. See Treat. of Fluxions, book 1. chap. 9. and book 2. chap. 5. art. 859. The greatest and least ordinates are likewise discovered in some cases, by supposing y to be infinite in respect of x. But there are several exceptions to this rule. See Maclaurin, loc. cit. art. 262, 865.

A late author has formed some objections to the universality of Mr. Maclaurin's rule. See the Harmony of Ancient and Modern Geometry, by Mr. Paman. Lond. 1745. 4to, in the Preface.

MAIXY, in *Mineralogy*, a name given by some to mundic, a sulphureous mineral, common in the tin-mines of Cornwall, and elsewhere.

MAY, Maius, the fifth month in the year, reckoning from our first or January; and the third, counting the year to begin with March, as the Romans anciently did. It was called *Maius* by Romulus, in respect to the senators and nobles of his city, who were named *majores*; as the following month was called *Junius*, in honour of the youth of Rome, *in honorem juventutis*, who served him in the war, though some will have it to have been thus called from *Maia*, the mother of Mercury, to whom they offered sacrifice on the first day of it; and Papias derives it from *Maius, eo quod tunc terra maderet*.

In this month the sun enters Gemini, and the plants of the earth in general begin to flower.

The month of *May* was under the protection of Apollo; and in it also they kept the festival of Bona Dea, that of the goblins, called LEMURIA; and the ceremony of REGIFUGIUM, or the expulsion of the kings.

The vulgar have a great opinion of the virtues of *May*-DEW, and *May*-WATER.

The month of *May* has ever been effected favourable to love; and yet the ancients, as well as many of the moderns, look on it as an unhappy month for marriage. The original reason may perhaps be referred to the feast of the Lemures, which was held in it. Ovid alludes to this in the fifth of his Fasti, when he says,

Nec viduæ tecta adeas, nec virginis ædes
Tempora cum medio nocte silentia fuit:
Hæc quoque de cœnis, sole petente cubile,
Mane mihi Maio nubere turba vide.

MAY *apple*. See DUCK's *foot*.

MAY *bush*. See MEDLAR.

MAY *drop*. See DEW.

MAY *duke*, a species of CHERRY.

MAY *lily*. See LILY *of the valley*.

MAY *weed*. See CHAMOMILE.

MAYA, in *Natural History*, a name given by the people of the Philippine islands to a small species of sparrow, much less than our's, and very common among them. It feeds on rice, and is very destructive of it.

MAYS. See MAIZE.

MAYHEM. See MAHIM.

MAYHEM, *appeal of*. See APPEAL.

MAYL, in *Falconry*, signifies to pinion the wings of a HAWK.

MAYOR, or MAIOR, the chief magistrate or governor of the cities, and most corporation-towns of England, chosen annually by his peers out of the number of the aldermen. See ALDERMAN.

The word, according to Verstegan, comes from the ancient English *maier*, *able*, *potent*, of the verb *may*, or *main*. The *mayor* of the place is the king's lieutenant, and, with the aldermen and common-council, can make laws, called *bye-laws*, for the government of the place. He has also the authority of a kind of judge, to determine matters, and to mitigate the rigour of the law.

King Richard I. A. D. 1189, first changed the bailiffs of London into *mayors*; by whose example others were afterwards appointed.

Mayors of corporations are justices of peace, *pro tempore*, and they are mentioned in several statutes; but no person shall bear any office of magistracy concerning the government of any town, corporation, &c. that hath not received the sacrament, according to the church of England, within one year before his election; and who shall not take the oaths of supremacy, &c. Stat. 13 Car. II. cap. 1.

MAYOR's *court*. See COURT.

MAZA, a name given by the ancients to a sort of food, in common use among the poorer sort of people. It is made of the meal of parched barley, sprinkled with some liquid, and was eaten with honey or with defrutum.

Hippocrates every where speaks of this as of a coarse kind of bread, and advises the changing the common finer bread, in the spring season, for this coarser kind, as a thing very conducive to health. He seems every where to consider bread as the drier, and *maza* the moister diet.

MAZA, Maza, among the Athenians, a sort of cake, which was the common fare of such as were entertained at the public expence in the common hall, or PRYTANEUM. These cakes were made with flour boiled with water and oil. Pasise. Lex. Ant. in voc.

MAZE, in *Gardening*. See LABYRINTH.

MAZONOMUS, among the *Ancients*, a very large dish, commonly of wood, in which the MAZA was served.

MAZORAH, among the Jews, denotes the science of reading the scriptures. See MASORAH.

MAZUR, a species of birds, which the Arabian sailors esteem very lucky, because it lays its eggs close by the seashore before good weather; so that when these are observed, they promise themselves a safe voyage. They also pretend that this bird gives notice to sailors, when the ship approaches any danger, by flying and fluttering up and down.

MEAD, a wholesome, agreeable liquor, prepared of honey and water.

One of the best methods of preparing *mead* is as follows: Into twelve gallons of water slip the whites of six eggs; mixing these well together, and to the mixture adding twenty pounds of honey. Let the liquor boil an hour, and when boiled, add cinnamon, ginger, cloves, mace, and a little rosemary. As soon as it is cold, put a spoonful of yest to it, and tun it up, keeping the vessel filled as it works; when it has done working, stop it up close; and, when fine bottle it off for use.

Thorley says, that *mead*, not inferior to the best of foreign wines, may be made in the following manner: put three pounds of the finest honey to one gallon of water, and two lemon peels to each gallon; boil it half an hour, well scummed; then put in, while boiling, lemon peel: work it with yest; then put it in your vessel with the peel, to stand five or six months, and bottle it off for use. If it is to be kept for several years, put four pounds to a gallon of water.

The author of the Dictionary of Chemistry directs to chuse the whitest, purest, and best-tasted honey, and to put it into a kettle with more than its weight of water: a part of this liquor must be evaporated by boiling, and the liquor scummed, till its consistence is such, that a fresh egg shall be supported on its surface, without sinking more than half its thickness into the liquor; then the liquor is to be strained, and poured through a funnel into a barrel; this barrel, which ought to be nearly full, must be exposed to a heat as equable as possible, from 20 to 27 or 28 degrees of Mr. Reaumur's thermometer, taking care that the bung-hole be slightly covered, but not closed.

closed. The phenomena of the spirituous fermentation will appear in this liquor, and will subsist during two or three months, according to the degree of heat; after which they will diminish and cease. During this fermentation, the barrel must be filled up occasionally with more of the same kind of liquor of honey, some of which ought to be kept apart, on purpose to replace the liquor which flows out of the barrel in froth. When the fermentation ceases, and the liquor has become very vinous, the barrel is then to be put into a cellar, and well closed: a year afterwards the *mead* will be fit to be put into bottles.

The duty on *mead*, sold by retail, or otherwise, is 11½*d.* a gallon, to be paid by the maker.

MEADIA, *Dodecatheon*, in *Botany*, a genus of the *pentandria monogynia* class. Its characters are these: the flower has a permanent empalement of one leaf, cut into five long segments, which are reflexed; the flower hath one petal cut into five parts, whose limb is reflexed backward; it has five short stamina, sitting in the tube, connected at the top with a conical germen, terminated by an oblique stigma; the empalement becomes an oblong oval capsule, with one cell, opening at the top, and filled with small seeds: we have but one species of this plant, which is a native of Virginia, and was named after Dr. Mead.

MEADOW, in *Husbandry*, in its general signification, means pasture, or grass land, annually mown for hay; but is more particularly applied to lands that are so low as to be too moist for cattle to graze upon them, in winter, without spoiling the sward.

Too much water, and too little are equally prejudicial to *meadow*-grounds. The best lands for *meadow*-pasture are either low lands, or hanging grounds, where there is a rich soil and a moist bottom; especially where any little brook, or running spring, may be brought over it; and where there is some descent in the *meadow*, that the water may not lodge on it. These *meadows* are much better for the farmer than those near large rivers, where great crops are often lost.

Those that may be overflowed at pleasure are called *water-meadows*; these should never be overflowed till the end of March, except once or twice in winter, when there are such floods as bring a great deal of soil from the upper lands: and, if the season should prove dry, it will be of great service to the grass, if the *meadows* are overflowed again; but then the cattle should not be turned in till the sward is dry enough to bear their weight. Miller recommends the weeding of *meadows* in April and October, with a spaddle, and rolling them with a heavy roller in spring and autumn.

MEADOW *grass*. See GRASS.

MEADOW *rue*. See RUE.

MEADOW *saffron*. See SAFFRON.

MEADOW *sweet*. See SPIRÆA.

MEADOW *trefoil*. See TREFOIL.

MEAL. The *meal* or flour of England is the finest and whitest in the world. The French is usually browner, and the German browner than that. Our flour keeps well with us, but in carrying abroad it often contracts damp, and becomes bad. All flour is subject to breed worms; these are white in the white flour, and brown in that which is brown; they are therefore not always distinguishable to the eye; but when the flour feels damp, and smells rank and musty, it may be conjectured that they are there in great abundance.

The colour and the weight, are the two things which denote the value of *meal* or flour; the whiter and the heavier it is, other things being alike, the better it always is. Pliny mentions these two characters as the marks of good flour, and tells us, that Italy, in his time, produced the finest in the world. This country, indeed, was famous before his time for this produce; and the Greeks have celebrated it; and Sophocles, in particular, says, that no flour is so white, or so good, as that of Italy.

The corn of this country has, however, lost much of its reputation since that time; and the reason of this seems to be, that the whole country being full of sulphur, alum, vitriol, marcasites, and bitumens, the air may have, in time, affected them so far, as to make them diffuse themselves through the earth, and render it less fit for vegetation: and the taking fire of some of these inflammable minerals, as has sometimes happened, is alone sufficient to alter the nature of all the land about the places where they are. Dessand. Trait. Phys.

The flour of England, though it pleases by its whiteness, yet it wants some of the other qualities valuable in flour: the bread that is made of it is brittle, and does not hold together, but after keeping a few days becomes hard and dry, as if made of chalk, and is full of cracks in all parts; and this must be a great disadvantage in it, when intended for the service of an army, or the like occasions where there is no baking every day, but the bread of one making must necessarily be kept a long time.

The flour of Picardy is very like that of England, and after it has been kept some time, is found improper for making into paste or dough. The French are forced either to use it immediately on the grinding, or else to mix it with an equal quantity of the flour of Britanny, which is coarser, but more unctuous and fatty; but neither of these kinds of flour keep well.

The flour of almost any country will do for the home consumption of the place, as it may be always fresh ground; but the great care to be used in selecting it is in order to the sending it abroad, or furnishing ships for their own use. The saline humidity of the sea-air rusts metals, and fouls every thing on board, if great care be not taken in the preserving them. This also makes the flour damp and mouldy, and is often the occasion of its breeding insects, and being wholly spoiled.

The flour of some places is constantly found to keep better at sea than that of others; and when that is once found out, the whole caution needs only be to carry the flour of those places. Thus the French find, that the flour of Poitou, Normandy, and Guienne, all bear the sea-carriage extremely well, and they make a considerable advantage by carrying them to their American colonies.

The choice of flour for exportation being thus made, the next care is to preserve it in the ships: the keeping it dry is the grand consideration in regard to this: the barrels in which it is put up ought to be made of dry and well-seasoned oak, and not to be larger than to hold two hundred weight at the most. If the wood of the barrels have any sap remaining in it, it will mouldy and spoil the flour; and no wood is so proper as oak for this purpose, or for making the bins and other vessels for keeping flour in at home, since, when once well dried and seasoned, it will not contract humidity afterwards. The beech-wood, of which some make their bins for flour, is never thoroughly dry, but always retains some sap. The fir will give the flour a taste of turpentine; and the ash is always subject to be eaten by worms. The oak is preferable, because of its being free from these faults; and when the several kinds of wood have been examined in a proper manner, there may be others found as fit, or possibly more so, than this for the purpose. The great test is their having more or less sap. See FLOUR and WOOD.

MEAL *worm*. See WORM.

MEALY *tree*. See WAYFARING *tree*.

MEAN, the *middle*, between two extremes.

Thus we say, the *mean* motion of a planet; its *mean* distance, &c. meaning a motion or distance, which as far exceeds the least distance or motion, as it is exceeded by the greatest.

MEAN, in *Logic*. See MEDIUM.

MEAN *anomaly*, in *Astronomy*. See ANOMALY.

MEAN *axis*, in *Optics*. See AXIS.

MEAN { *conjunction*, / *opposition*, } in *Astronomy*, is when the *mean* place of the sun is in { *conjunction*, / *opposition*, } with the *mean* place of the moon in the ecliptic. See CONJUNCTION and OPPOSITION.

MEAN *diameter*, in *Gauging*. See DIAMETER and GAUGING.

MEAN *distance of a planet from the sun*, in *Astronomy*, is the right line drawn from the sun, to the extremity of the conjugate axis of the ellipsis in which the planet moves; and this is equal to the semitransverse axis, and is so called because it is a *mean* between the planet's greatest and least distance from the sun.

MEAN *motion*, in *Astronomy*, that whereby a planet is supposed to move equally in its orbit, and is always proportional to the time.

MEAN *proportion*. See EXTREME *proportion*.

MEAN *time*. See TIME.

MEAN, in *Law*, refers either to time, or dignity. Thus, in the first sense we say, his action was *mean* between the disseisin made to him, and his recovery; i. e. in the interim.

In the second sense, we say, there is lord *mean* or MESNE.

MEASLES, *morbilli*, in *Medicine*, a cutaneous disease, consisting in a general appearance of eruptions, not tending to suppuration; accompanied with a fever.

This distemper seems to bear a great affinity to the small-pox, and appeared in Europe about the same time with it: the symptoms being in many respects the same, the cause nearly the same, and the regimen and cure not much different.

The *measles* are most common in the spring season, and generally disappear in summer: they are preceded, like other fevers, by alternate fits of heat and cold, with sickness, and loss of appetite: the tongue is white, but generally moist; there is a short cough, a heaviness of the head and eyes, drowsiness, and a running at the

nose; but sometimes the cough does not come before the eruption has appeared. There is an inflammation and heat in the eyes, accompanied with a defluxion of sharp tears, and great acuteness of sensation, so that they cannot bear the light without pain: the eye-lids frequently swell so as to occasion blindness. The patient generally complains of his throat; and a vomiting or looseness often precedes the eruption. The stools in children are commonly greenish: they complain of an itching of the skin, and are remarkably peevish. Bleeding at the nose is common, both before, and in the progress of the disease. The eruptions, which, Dr. Watson observes, are merely symptomatic, and not critical as in the small-pox, usually appear about the fourth day, like flea-bites, first on the face, then upon the breast, and afterwards on the extremities. These may be distinguished from the small-pox by their scarcely rising above the skin. The fever, cough, and difficulty of breathing, instead of being removed by the eruption, as in the small-pox, are rather increased, but the vomiting generally ceases. About the sixth or seventh day, from the time of sickening, the *measles* begin to turn pale upon the face, and afterwards upon the body; so that by the ninth day they entirely disappear. The fever, however, and difficulty of breathing often continue, especially if the patient has been kept upon too hot a regimen. A violent looseness sometimes succeeds the *measles*, in which case the patient's life is in imminent danger. Those who die of the *measles*, generally expire about the ninth day from the invasion, and are commonly carried off by a peripneumony, or inflammation of the lungs. The most favourable symptoms are a moderate looseness, a moist skin, and a plentiful discharge of urine. The dangerous symptoms are a sudden disappearance of the spots, a delirium, great weakness, vomiting, restlessness, and difficulty of swallowing. If the spots turn pale too soon, or purple spots appear among them, these are unfavourable symptoms. When a continual cough, with hoarseness, succeeds the disease, there is reason to suspect an approaching consumption of the lungs. The regimen in this disease should be cool, the food light, and the drink diluting. Acids and small beer are not so proper in the *measles* as in the small-pox. The most suitable liquors are decoctions of liquorice with marsh-mallow roots and sarsaparilla, infusions of linseed, or of the flowers of elder, baum tea, clarified whey, barley water, &c. which, if the patient be costive, may be sweetened with honey, or mixed occasionally with a little manna. Bleeding is commonly necessary in this disease, especially when the fever runs high, and is attended with difficulty of breathing. Bathing the feet and legs in lukewarm water, and, when there is a tendency to vomiting, warm water or weak camomile tea, in order to encourage it, will be serviceable. The throat may be softened, and the tickling cough relieved, by licking sperma-ceti and sugar-candy pounded together; or by taking occasionally a spoonful of the oil of sweet almonds, with sugar-candy dissolved in it; or by drawing the steam of warm water into the lungs. If the *measles* should suddenly disappear, recourse must be had to the same treatment as in the similar circumstance of the SMALL-*pox*, the patient must be supported with wine and cordials. Blistering plasters must be applied to the legs and arms, and the body rubbed with warm flannels. Warm poultices may also be applied to the feet and palms of the hands. When purple or black spots appear, the patient's drink should be sharpened with spirits of vitriol; and if the putrid symptoms increase, the Peruvian bark must be administered, as in the small-pox.

This practice of giving the bark in the *measles* was first introduced by Dr. Cameron of Worcester, who observes, that it prevents the retrocession of the morbid acrimony, and continues the efflorescence on the skin, sometimes so long as the twelfth day. In this way, says Dr. Percival, the cough and other inflammatory symptoms are in a great measure obviated; and the patient is freed from all danger of a peripneumony, the fatality of which Sydenham describes in such strong terms.

Opiates should never be given except in cases of extreme restlessness, a violent looseness, or when the cough is very troublesome. For children, the syrup of poppies is sufficient; and a tea-spoonful or two may be occasionally given, according to the age of the patient, or the violence of the symptoms. When the *measles* are gone off, the patient ought to be purged, as in the small-pox: and if it is succeeded by a diarrhœa, this may be checked by a gentle dose of rhubarb, taken for some days in the morning, and an opiate at night: and if these fail, bleeding will be commonly effectual.

The *measles* is a disease more troublesome than dangerous; though it often inclines to consumptions, by a cough which it leaves behind. If such symptoms appear, small quantities of blood may be often let at proper intervals; and the patient should drink asses milk, remove to a sweet air, if in a large town, and ride daily on horseback; and keep close to a diet of milk and vegetables.

The *measles* may be inoculated by means of the hot sharp rheum which distils from the eyes, or blood, or by means of flannels placed under the arm-pits, or cotton rubbed upon the skin, and applied where the puncture is made. Tissot assures us, that he practised the INOCULATION of the *measles* for twelve years, with great success. Dr. Home, of Edinburgh, proposed, by inoculating the *measles*, to lessen its mortality, and to prevent the cough and other disorders, which are the consequences of the disease in the natural way: and his experience must [illegible] the advantages of this practice, and that it [illegible] exceed those which attend the inoculation of the small-pox. Buchan's Dom. Med. chap. 24. art. [illegible] vol. 5. art. 25. London Med. Obs. vol. 4. [illegible] Med Facts and Exp. Tissot's Advice, p. 235.

MEASNE. See MESNE.

MEASURE, MENSURA, in *Geometry*, denotes any certain quantity assumed as one, or unity, to which the ratio of other homogeneous or similar quantities is expressed.

This definition is somewhat more agreeable to practice than that of Euclid, who defines *measure* a quantity, which being repeated any number of times, becomes equal to another. Which only answers to the idea of an arithmetical *measure*, or quota part.

MEASURE *of an angle* is an arch described from the vertex *a*, *fig. 60.* III. *Geomet. fig. 60.* in any place between its legs; as at *d f*.

Hence angles are distinguished by the ratio of the arches, described from the vertex between the legs, to the peripheries.

Angles then are distinguished by those arches; and the arches are distinguished by their ratio to the periphery. Thus the angle *f a c* is said to be of so many degrees as there are in the arch *f d*. See ANGLE.

To *measure* the height of a hill, see the latter part of the article LEVELLING.

MEASURE *of a figure*, or plane surface, is a square, whose side is one inch, foot, yard, or some other determinate length.

Among geometricians, it is usually a rod, called a *square rod*, divided into ten square feet, and the square feet into square digits. Hence square *measures*.

MEASURE *of a line* is any right line taken at pleasure, and considered as unity.

The modern geometricians use a decempeda, or rod, divided into ten equal parts, called *feet*. The feet they subdivide into ten digits, the digit into ten lines, &c. This decimal division of the *measure* was first introduced by Stevinus, probably from the example of Regiomontanus. The index or character of the decempeda is made 0, that of feet 1, of digits 2, of lines 3, &c. which, because the *measure* was subdivided in a triple ratio, were the logarithms of the division. But, in lieu of these, expressed the logarithms by the Roman characters; v. g. 5 perches, 4 feet, 3 digits, and 2 lines, be expressed thus 5', 4, 3'', 2'''. It is frequently most commodious to separate the integers, or rods, from the fractions, by a point; thus, instead of 5', 4, 3'', 2''', to write 5.432. F. Noel observes, that, among the Chinese, the decimal division obtains in their common *measures*, and even in their weights.

MEASURES, *line of*. See LINE.

MEASURE *of the mass*, or *quantity of matter*, in *Mechanics*, is its weight; it being apparent, that all the matter which coheres and moves with a body, gravitates with it: and it being found by experiment, that the gravities of homogeneal bodies are in proportion to their bulks; hence, while the mass continues the same, the absolute weight will be the same, whatever figure it put on; but, as to its specific weight, it varies as the quantity of surface varies. See WEIGHT.

MEASURE *of a number*, in *Arithmetic*, is such a number as divides another, without leaving any fraction; thus 9 is a *measure* of 27.

MEASURE, *common*. See COMMON *measure*.

MEASURE *of a solid* is a cube, whose side is one inch, foot, yard, or other determined length.

Among geometricians, it is sometimes a rod or perch, called a *cubic perch*; divided into cubic feet, digits, &c. Hence cubic *measures*, or *measures* of capacity. See CUBE and TIMBER.

MEASURE *of velocity*, in *Mechanics*, is the space passed over by a moving body in any given time.

To *measure* a velocity, therefore, the space must be divided into as many equal parts as the time is conceived to be divided into. The quantity of space answering to such an article of time, is the *measure* of the velocity.

MEASURE, *universal* and *perpetual*, is a kind of *measure* unalterable by time, to which the *measures* of different nations and ages might be reduced, and by which they

might be compared and eſtimated. Such a *meaſure* is very deſirable, if it could be attained. Huygens, in his Horol. Oſcill. propoſes, for this purpoſe, the length of a pendulum, vibrating ſeconds, taken from the point of ſuſpenſion to the point of oſcillation. The third part of ſuch a pendulum may be called the horary foot, and ſerve as a ſtandard to which the *meaſure* of all other feet may be referred. Thus, v. g. the proportion of the Paris foot to the horary foot would be that of 864 to 881; becauſe the length of 3 Paris feet is 864 half lines, and the length of a pendulum, vibrating ſeconds, contains 3 horary feet, or 3 feet 8 ½ lines, i. e. 881 half lines. But this *meaſure*, in order to its being univerſal, ſuppoſes, that the action of gravity is every where the ſame, which is contrary to fact; and, therefore, it would really ſerve only for places under the ſame parallel of latitude; and in order to its being perpetual, it ſuppoſes, that the action of gravity continues always the ſame in the ſame place. See PENDULUM.

MEASURE, in a legal, commercial and popular ſenſe, denotes a certain quantity or proportion of any thing, bought, ſold, valued, or the like.

The regulation of WEIGHTS and *meaſures* ought to be univerſally the ſame throughout the kingdom, and ſhould, therefore, be reduced to ſome fixed rule or ſtandard; the prerogative of fixing which was veſted, by our ancient law, in the crown. This ſtandard was originally kept at Wincheſter: and we find, in the laws of king Edgar, cap. 8. near a century before the Conqueſt, an injunction, that the one *meaſure*, which was kept at Wincheſter, ſhould be obſerved throughout the realm. With reſpect to *meaſures* of length, our ancient hiſtorians (Will. Malm. in Vita Hen. I. Speim. Hen. I. apud Wilkins, 299.) inform us, that a new ſtandard of longitudinal *meaſure* was aſcertained by king Henry I. who commanded that the ulna, or ancient ell, which anſwers to the modern yard, ſhould be made of the exact length of his own arm: and one ſtandard of *meaſures* of length being once gained, all others are eaſily derived from hence; thoſe of greater length by multiplying, thoſe of leſs by ſubdividing the original ſtandard. Upon theſe principles the ſtandards were firſt made; which, being originally ſo fixed by the crown, their ſubſequent regulations have been generally made by the king in parliament. Thus, under king Richard I. in his parliament holden at Weſtminſter, A. D 1197, it was ordained, that there ſhould be only one weight and one *meaſure* throughout the kingdom, and that the cuſtody of the aſſize or ſtandard of weights and *meaſures* ſhould be committed to certain perſons, in every city and borough. See ALNAGER. In king John's time, this ordinance of king Richard was frequently diſpenſed with for money; (Hoved. A. D. 1202.) which occaſioned a proviſion to be made for inforcing it, in the great charters of king John and his ſon.

The ſtatute of Magna Charta, cap. 25, ordains, that there ſhall be but one *meaſure* throughout England, according to the ſtandard of the Exchequer; which ſtandard was formerly kept in the king's palace; and in all cities, market-towns, and villages, it was kept in the churches. By 17 Car. I. cap. 19. there is to be one weight and *meaſure*, and one yard, according to the king's ſtandard, and whoſoever ſhall keep any other weight or *meaſure*, whereby any thing is bought or ſold, ſhall forfeit for every offence 5l. And by 22 Car. II. cap. 8. water *meaſure*, as to corn and grain, or ſalt, is declared to be within the ſtatute 17 Car. I. And if any ſell grain or ſalt, &c. by any other buſhel, or *meaſure*, than what is agreeable to the ſtandard in the Exchequer, commonly called Wincheſter *meaſure*, he ſhall forfeit 40s. &c. Notwithſtanding theſe ſtatutes, in many places and counties there are different *meaſures* of corn and grain; and the buſhel in one place is larger than in another; but the lawfulneſs of it is not well to be accounted for, ſince cuſtom or preſcription is not allowed to be good againſt a ſtatute. Selling by falſe *meaſure* being an offence by the common law, may be puniſhed by fine, &c. upon an indictment at common law, as well as by ſtatute. See the ſtatute 11 Hen. VII. cap. 4. which inflicts particular fines for offences, pillory, &c.

Meaſures are various, according to the various kinds and dimenſions of the things *meaſured*. Hence ariſe

MEASURES, *lineal* or *longitudinal*, for lines or lengths:

MEASURES, *ſquare*, for areas or ſuperficies; and

MEASURES, *ſolid* or *cubic*, for bodies and their capacities.

All which again are very different in different countries, and in different ages, and even many of them for different commodities. Whence ariſe other diviſions of *domeſtic* and *foreign meaſures*, *ancient* and *modern* ones, *dry* and *liquid meaſures*, &c. The buſineſs of *meaſure* has been ſo confuſedly and imperfectly delivered by Engliſh writers, that the reader will not be diſpleaſed with the pains we have here taken to diſembroil and ſupply it. Under this head he will find enumerated the various general ſtanding *meaſures*, long, ſquare, and cubic, now or heretofore in uſe, with their proportions and reductions: for particulars, he muſt be contented to be referred to the particular heads; as FOOT, DIGIT, ELL, TUN, GALLON, BUSHEL, PERCH, LEAGUE, FURLONG, &c.

MEASURES, *long*, or MEASURES *of application*. *The Engliſh ſtandard long* MEASURE, for commerce, or that whereby the quantities of things are ordinarily eſtimated in the way of trade, is the yard; containing three Engliſh feet; equal to three Paris feet one inch $\frac{7}{10}$ of an inch; or $\frac{8}{9}$ of a Paris ell. Its diviſions are the foot, ſpan, palm, inch, and barley-corn, which ſee under their reſpective heads. Its multiples are the pace, fathom, pole, furlong, and mile. The proportions theſe ſeverally bear to each other will be expreſſed in a table for the purpoſe.—*Aſſay of meaſures*. See ASSAY.

MEASURE, *the French ſtandard*, for commerce, is the aune or ell, containing three Paris feet ſeven inches eight lines, or one yard $\frac{1}{8}$ Engliſh; the Paris foot royal exceeding the Engliſh by $\frac{1}{1000}$ parts, as in one of the following tables. This ell is divided two ways viz. into halves, thirds, ſixths, and twelfths; and into quarters, half-quarters, and ſixteenths.

This ell holds throughout the greateſt part of France; excepting at Troyes, in Champagne; at Arc, in the Barrois; and in ſome parts of Picardy and Burgundy, where the ell contains only two feet five inches one line; in Bretagne, where it contains four feet two inches eleven lines; and at St. Genoux, in Berry, where it exceeds the Paris ell by eight lines. See ELL. But in Languedoc, particularly at Marſeilles, Montpelier, Thouloufe, in Provence, and in Guienne, they meaſure by the canna, which at Thouloufe, and in Guienne, contains five Paris feet five inches and ſix lines; or one Paris ell and a half. But at Montpelier, and throughout the Lower Languedoc, as alſo in Provence and Avignon, and even Dauphine, the canna is ſix feet and nine lines, or one Paris ell and two thirds. See CANNA.

We have lately had ſome accurate compariſons between ſome of the French weights and *meaſures*, and thoſe of England, the reſult of which is, 1. The Paris half toiſe, as ſet off on the ſtandard kept in the Royal Society, contains of Engliſh inches, by the ſame ſtandard, 38.355, whence it appears, that the Engliſh yard and foot are, to the Paris half toiſe and foot, *nearly* as 107 to 114 ſo as 36 to 38.35514.

2. The Paris two marc, or fifteen ounce weight, weighs Engliſh troy grains 7560; whence it appears, that the Engliſh troy pound of twelve ounces, or 5760 grains, is to the Paris two marc, or fifteen ounce weight, as 16 to 21; that the Paris ounce weighs Engliſh troy grains 472.5, and that conſequently the Engliſh troy ounce is to the Paris ounce as 64 is to 63.

3. The Engliſh avoirdupois pound weighs troy grains 7004; whence the avoirdupois ounce, whereof ſixteen make a pound, is found equal to 437.75 troy grains.—And it follows, that the troy pound is to the avoirdupois pound as 88 to 107 nearly; for as 88 to 107 ſo is 5760 to 7003.636: that the troy ounce is to the avoirdupois ounce, as 80 to 73 nearly; for as 80 to 73 ſo is 480 to 438. And, laſtly, that the avoirdupois pound and ounce is to the Paris two marc weight and ounce, as 63 to 68 nearly; for as 63 to 68 ſo is 7004 to 7559.873. See WEIGHT.

4. The Paris foot, expreſſed in decimals, is equal to 1.0654 of the Engliſh foot, or contains 12.785 Engliſh inches. Phil. Tranſ. N° 465 ſect. 5. See FOOT.

MEASURE, *the ſtandard, in Holland, Flanders, Sweden*, a good part of *Germany*, many of the Hans-towns, as *Dantzick*, and *Hamburgh*, and at *Geneva*, *Frankfort*, &c. is likewiſe the ell: but the ell, in all theſe places, differs from the Paris ell. In Holland, it contains one Paris foot eleven lines, or four ſeventhsof the Paris ell. The Flanders ell contains two feet one inch five lines and half a line; or ſeven twelfths of the Paris ell. The ell of Germany, Brabant, &c. is equal to that of Flanders.

MEASURE, *the Italian*, is the bracchio, brace, or fathom: this obtains in the ſtates of Modena, Venice, Florence, Lucca, Milan, Mantua, Bologna, &c. but is of different lengths. At Venice, it contains one Paris foot eleven inches three lines, or eight fifteenths of the Paris ell. At Bologna, Modena, and Mantua, the brace is the ſame as at Venice. At Lucca it contains one Paris foot nine inches ten lines, or half a Paris ell. At Florence, it contains one foot nine inches four lines, or forty-nine hundredths of a Paris ell. At Milan, the brace for meaſuring of ſilks is one Paris foot ſeven inches four lines, or fourth ninths of a Paris ell: that for woollen cloths is the ſame with the ell of Holland. Laſtly, at

Bergamo,

Bergama, the brace is one foot feven inches fix lines, or five nipthe of a Paris ell. The uſual *meaſure* at Naples, however, is the canna, containing ſix feet ten inches and two lines, or one Paris ell and fifteen ſeventeenths.

MEASURE, *the Spaniſh*, is the vara, or yard, in ſome places called the barra; containing ſeventeen twenty-fourths of the Paris ell. But the *meaſure* in Caſtile and Valencia is the pan, ſpan, or palm; which is uſed, together with the canna, at Genoa. In Arragon, the vara is equal to a Paris ell and a half, or five feet five inches ſix lines.

MEASURE, *the Portugueſe*, is the cavedo, containing two feet, eleven lines, or four ſeventhe of a Paris ell; and the varra, a hundred and ſix whereof make a hundred Paris ells.

MEASURE, *the Piedmonteſe*, is the ras, containing one Paris foot nine inches ten lines, or half a Paris ell.

In Sicily, their *meaſure* is the canna; the ſame with that of Naples.

MEASURES, *the Muſcoviſe*, are the cubit, equal to one Paris foot four inches two lines; and the arcin, two whereof are equal to three cubits.

MEASURES, *the Turkiſh* and *Levant*, are the pick, containing two feet two inches and two lines, or three ſixths of the Paris ell. The Chineſe *meaſure*, the cobre; ten whereof are equal to three Paris ells. In Perſia, and ſome parts of the Indies, the gueze, whereof there are two kinds; the royal gueze, called alſo the *gueze mahaſſer*, containing two Paris feet ten inches eleven lines, or four fifths of the Paris ell; and the ſhorter gueze, called ſimply *gueze*, only two thirds of the former. At Goa and Ormuz, the *meaſure* is the vara, the ſame with that of the Portugueſe, having been introduced by them. In Pegu, and ſome other parts of the Indies, the cubit or candi, equal to the ell of Venice. At Goa, and ſome parts, they uſe a larger candi, equal to ſeven Paris ells; exceeding that of Babel and Baſſora by [illegible] and the vara by 6¼. In Siam, they uſe the ken, which is three Paris feet by one inch. The ken contains two ſoks, the ſok two keubs, the keub twelve nious or inches, the niou to be equal to eight grains of rice, i.e. to about nine lines. At Camboia, they uſe the haſter; in Japan, the tatam; and the ſpan on ſome of the coaſts of Guinea.

Proportions of several long MEASURES *to each other, by M. Picard.*

The Rhinland or Leyden foot (12 whereof make the Rhinland perch) supposed	696
The English foot	675⅝
The Paris foot	720
The Amsterdam foot, from that of Leyden, by Snellius	629
The Danish foot (two whereof make the Danish ell)	701,⅛
The Swedish foot	658⅛
The Brussels foot	609⅛
The Dantzic foot, from Hevelius's Selenographia	636
The Lyons foot, by M. Auzout	757⅞
The Bologna foot, by the same	843
The braccio of Florence, by the same, and father Mersenne	1290
The palm of the architects at Rome, according to the observations of Messi. Picard and Auzout	494⅛
The Roman foot in the Capitol, examined by Messi. Picard and Auzout	653 or 653⅛
The same from the Greek foot	652
From the vineyard Mattei	657⅛
From the palm	658⅛
From the pavement of the Pantheon, supposed to contain ten Roman feet	653
From a slip of marble in the same pavement, supposed to contain 3 Roman feet	650
From the pyramid of Cestius, supposed to contain 95 Roman feet	653⅛
From the diameters of the columna in the arch of Septimius Severus	653⅛
From a slip of porphyry in the pavement of the Pantheon	653⅛

See on this subject Phil. Transf. vol. li. art. 69. p. 774.

Proportions of the Long MEASURES *of several nations to the English foot, taken from Mr. Greaves, Auzout, Picard, and Eisenschmid.* See FOOT.

The English standard foot being divided into 1000 equal parts, the other *measures* will have the proportions to it, which follow:

	Feet	Inches
English foot	1000	12
Paris foot	1068	12,816
Venetian foot	1162	13,944
Rhinland foot	1033	12,396

Paris mercer's ell	3937	47,244

MEASURES, *square or superficial.* English square or superficial *measures* are raised from the yard of 36 inches, multiplied into itself; and this producing 1296 square inches in the square yard, the divisions of this are square feet and inches; and the multiples, poles, roods, and acres, as in the table.

French square measures are regulated by 12 square lines in the inch square; 12 inches in the foot, 22 feet in the perch, and 100 perches in the arpent or acre.

English square MEASURES.

MEASURES, *cubical*, or MEASURES *of capacity for liquids. Engliſh liquid meaſures* were originally raiſed from troy-weight; it being enacted by ſeveral ſtatutes, that eight pounds troy of wheat, gathered from the middle of the ear, and well dried, ſhould weigh a gallon of wine *meaſure*; the diviſions and multiples whereof were to form the other *meaſures*: at the ſame time it was alſo ordered, that there ſhould be but one *liquid meaſure* in the kingdom; yet cuſtom has prevailed, and there having been introduced a new weight, viz. the avoirdupois, we have now a ſecond ſtandard gallon adjuſted thereto, and therefore exceeding the former in the proportion of the avoirdupois weight to troy weight. From this latter ſtandard are raiſed two ſeveral *meaſures*, the one for ale, the other for beer. For the method of reducing one into the other, ſee WEIGHT.

The ſealed gallon at Guildhall, which is the ſtandard for wines, ſpirits, oils, &c. is ſuppoſed to contain 231 cubic inches; and, on this ſuppoſition, the other *meaſures* raiſed therefrom will contain as in the following tables; yet, by actual experiment made in 1688, before the lord mayor and the commiſſioners of exciſe, this gallon was only found to contain 224 cubic inches: it was however agreed to continue the common ſuppoſed contents of 231 cubic inches, ſo that all computations ſtand on their old footing. Hence, as 12 is to 231, ſo is 14½ to 281¼, the cubic inches in the ale gallon; but in effect the ale quart contains 70½ cubic inches; on which principle the ale and beer gallon will be 282 cubic inches. See on this ſubject Phil. Tranſ. vol. xlvi. art. 15. p. 54.

The ſeveral diviſions and multiples of theſe *meaſures*, and their proportions, are exhibited in the tables underneath.

MEASURES, *French liquid*. At Paris, and in a great part of the kingdom, the *meaſures*, to begin with the ſmalleſt, are, the poſſon, which contains ſix cubic inches, or four Paris ounces of water at the freezing point: two poſſons make the demi-ſeptier; two demi-ſeptiers, the ſeptier or chopine; two chopines, a pint; two pints, the quart or pot; four quarts, the gallon, or ſeptier of eſtimation; and thirty-ſix ſeptiers, the muid, which is ſubdivided into two demi-muids, four quarter-muids, and eight half-quarter-muids. From the quart are likewiſe raiſed the *meaſures* uſed in other parts, as the queue uſed in Orleans, Blois, &c. containing a Paris muid and a half, or four hundred and twenty pints; the tun uſed at Bayonne and Bourdeaux, conſiſting of four barriques, and equal to three Paris muids; at Orleans to two; ſo that the firſt tun contains eight hundred and ſixty-four pints, and the ſecond five hundred and ſeventy-ſix. See TUN.

The demi-queue, uſed in Champagne, ninety-ſix quarts; the pipe, uſed in Anjou and Poictou, containing two hollards, equal to two demi-queues of Orleans, &c. or a muid and a half of Paris, or four hundred and thirty-two pints. The millerolle uſed in Provence, containing ſixty ſix Paris pints; and the poinçon uſed at Nantes, in Touraine, and the Iſle-de-France, equal to half the Orleans tun. The poinçon uſed at Paris is the ſame with the demi-queue.

MEASURES, *Dutch liquid*. At Amſterdam, their *meaſures*, to begin with the diminutions, are mengles, or bottles, equal to French pots, and containing two pounds four ounces, mart, of an ordinary liquor. The mengle is diviſed into two pints, four half-pints, eight mauſſes, ſixteen half-mauſſes, &c. Seven hundred and ſeventy mengles make their tun. The viertel, or quarter, conſiſts of five mengles, and one-ſixth of a mengle. The wine viertel is juſt ſix mengles. The ſtekan, or ſtekanmen, contains ſixteen mengles. The anker contains two ſtekans; and four ankers, the awm. For oils they uſe the tun, which contains ſix awms, or ahms; equal to ſixteen hundred Paris pints. See AAM.

MEASURES, *Spaniſh liquid*, are, the bota, containing between thirty-ſix and thirty-ſeven Dutch ſtekans, holding about a thouſand weight. The bota conſiſts of thirty arrobas, each weighing twenty-eight pounds. Each arroba is again divided into eight azumbres, and the azumbre into four quarts. The pipe conſiſts of eighteen arrobas.

MEASURES, *Portugueſe liquid*, are botas, almudes, cavadas, quartas; and for oil, alquiers, or cantars. The Portugueſe bota is ſomewhat ſmaller than the Spaniſh; the latter being equal to thirty-ſix or thirty-ſeven ſtekans, and the former only to twenty-five or twenty-ſix. The quartas is one-fourth of the cavadas. The cavadas, or cavado, is the ſame with the Dutch mengle. Six cavadas make an alquier, and two alquiers one almude, or almoud; twenty-ſix almudes, a bota.

MEASURES, *Italian liquid*. At Rome is the boccale, or pot, containing a little more than a Paris pint. Seven boccales and a half make the rubbo; and thirteen rubbos and a half, the brenta; ſo that the brenta contains ninety-ſix boccales. At Florence, the ſtaro, or ſtaio, containing three bariles, and the barile twenty-ſix fiaſcos, or flaſks, which are nearly equal to Paris pints. At Verona they uſe the baſſa, ſixteen whereof make a brenta; the bronta contains ninety-ſix boccales, or thirteen rubbos and a half. At Venice the amphora, containing two bottes; the botte, four bigoncios; the bigoncio, four quarts; the quart, four tiſchauffezas. The Venetian botte is again divided into moſtachios, ſeventy-ſix whereof make the amphora. At Ferrara the maſſilly, containing eight ſechios. In Iſtria, ſechios; ſix whereof make the urna. In Calabria, and Apulia, pignatolis, equal to French pints; thirty-two pignatolis make the ſtaro or ſtaio; and ten ſtaros, the ſalma.

MEASURES, *German liquid*. The fuder is uſed almoſt throughout all Germany, but with ſome difference in its length, as well as its ſubdiviſions. The fuder is ſuppoſed the load of a cart with two horſes. Two fuders and a half make the roeder; ſix awms, the fuder; twenty-ſertels, the awm; and four maſſems, or maaſſes, the fertel; ſo that the roeder contains one thouſand two hundred maaſſes, the fuder four hundred and eighty, the awm eighty, and the fertel forty-one. At Nuremberg, the diviſion of the fuder is into twelve heemers, and the heemer into forty-four maaſſes. At Vienna, they divide the fuder into thirty-two heemers, the heemer into thirty-two oehtelings, and the achtelling into four ſeltins: the awm, there, is eighty maaſſes; the fertel, called alſo *ſchenck*, four maaſſes; and the drieling twenty-four heemers. At Augſbourg, the fuder is divided into eight jez; the jez into two muids, or twelve beſons; the beſon into eight maaſſes, which makes ſeven hundred ſixty-eight maaſſes in the fuder, as in that of Nuremberg. At Heidelberg, the fuder is divided into ten awms; the awm into twelve vertels; and the vertel into four maaſſes. In Wirtemberg, the fuder is divided into awms; the awm into ſixteen eymes; the eyme into ten maaſſes.

MEASURES, *liquid, on the coaſts of Barbary*. At Tripoli, &c. they uſe the rotolo, or roſoli; thirty-two whereof make the matulo. At Tunis, forty-two of the roſoli of Tripoli make a matara, or mutaro; and the other places on the ſame coaſt uſe nearly the ſame *meaſures*. It may be here obſerved, that moſt, if not all the eaſtern nations, with whom the Europeans traffic, have not any ſuch thing as *meaſures* of capacity, whether for things liquid or dry; but that they ſell every thing, even liquors, by the weight. We may, however, rank among the number of *liquid meaſures*, the cocoa and canan of Siam. The firſt are the cocoa ſhells cleared of their kernel. And ſince theſe are not all of the ſame capacity, they meaſure them with cauris, or little ſhells found in the Maldives, which alſo ſerve for money in ſome ſtates of the Indies. Some cocoa hold a thouſand cauris, and ſome only five hundred. Above the cocoa is the canan, a little *meaſure* uſed in the ſame country, and called by the Portugueſe *chopa*; holding about a Paris quart.

MEASURES, *cubical, of capacity for things dry. Engliſh dry or corn* MEASURES are raiſed from the Winchester gallon, which contains 272¼ ſolid inches, and is to hold of pure running or rain water, nine pounds thirteen ounces. This ſeems to ſtand on the foot of the old wine gallon, of 224 cubic inches; 12 being to 14½, as 224 to 272¼. Yet by an act of parliament, made 1697, it is decreed, that a round buſhel, eighteen inches and a half wide, and eight deep, is a legal Winchester buſhel. But ſuch a veſſel will only hold 2150,42 cubic inches; conſequently the gallon will contain 268¼ cubic inches. The diviſions and multiples are in the table following.

MEASURES, *French dry*, are, the litron, buſhel, minot, mine, ſeptier, muid, and tun. The litron is divided into two demilitrons, and four quarter-litrons, and contains thirty-ſix cubic inches of Paris. By ordonnance, the litron is to be three inches and a half high, and three inches ten lines broad. The litron for ſalt is larger, and is divided into two halves, four quarters, eight demi-quarters, and ſixteen meſurettes. The French buſhel is different in different juriſdictions. At Paris it is divided into demi-buſhels; each demi-buſhel into two quarts; the quart into two half-quarts; and the half-quart into two litrons: ſo that the buſhel contains ſixteen litrons. By ordonnance, the Paris buſhel is to be eight inches, two lines and an half, high; and ten inches broad, or in diameter, within-ſide. The minot conſiſts of three buſhels; the mine of two minots, or ſix buſhels; the ſeptier of two mines, or twelve buſhels; and the muid of twelve ſeptiers, or an hundred forty-four buſhels. *The buſhel of oats* is eſtimated double that of any other grain; ſo that there go twenty-four buſhels to make the ſeptier, and two hundred eighty-eight to make the muid. It is divided into four picotins; the picotin containing two quarts, or four litrons. *The buſhel for ſalt* is divided into two half-buſhels, four quarters, eight half-quarters, and ſixteen litrons; four buſhels make a minot, ſixteen a ſeptier, and a hundred ninety-two a muid. *The buſhel for wood* is divided into halves, quarters, and half-quarters. Eight buſhels make the minot, ſixteen a mine; twenty mines, or three hundred and twenty buſhels, the muid. For *plaſter*, twelve buſhels make a ſack, and thirty-ſix ſacks a muid. For *lime*, three buſhels make a minot, and forty-eight minots a muid. The minot is, by ordonnance, to be eleven inches nine lines high; and fourteen inches eight lines in diameter. The minot is compoſed of three buſhels, or ſixteen litrons; four minots make a ſeptier, and forty-eight a muid. The French mine is no real veſſel, but an eſtimation of ſeveral others. At Paris, the mine contains ſix buſhels, and twenty-four make the muid; at Rouen, the mine is four buſhels; and at Dieppe, eighteen mines make a Paris muid. See MUID. The ſeptier differs in different places: at Paris it contains two mines, or eight buſhels; and twelve ſeptiers the muid. At Rouen the ſeptier contains two mines or twelve buſhels. Twelve ſeptiers make a muid at Rouen, as well as at Paris; but twelve of the latter are equal to fourteen of the former. At Toulon, the ſeptier contains a mine and a half; three of which mines make the ſeptier of Paris. See SEPTIER. The muid, or muy, of Paris, conſiſts of twelve ſeptiers: and is divided into mines, minots, buſhels, &c. That for oats is double that for other grain; i. e. contains twice the number of buſhels. At Orleans, the muid is divided into mines; but thoſe mines only contain two Paris ſeptiers and a half. In ſome places they uſe the tun in lieu of the muid; particularly at Nantes, where it contains ten ſeptiers of ſixteen buſhels each, and weighs between two thouſand two hundred and two thouſand two hundred and fifty pounds. Three of theſe tuns make twenty-eight Paris ſeptiers. At Rochel, &c. the tun contains forty-two buſhels, and weighs two per cent. leſs than that of Nantes. At Breſt, it contains twenty buſhels, is equal to ten Paris ſeptiers, and weighs about two thouſand two hundred and forty pounds. See [illegible]

MEASURES, *Dutch, Swediſh, Poliſh, Pruſſian, and eaſtern dry*. In theſe places they eſtimate their [illegible] on the foot of the *laſt, laſt, leth*, or *lecht*; ſo [illegible] cording to the various pronunciations of the [illegible] uſe it. In Holland, the laſt is equal to nineteen Paris ſeptiers, or thirty-eight Bourdeaux buſhels, and weighs about four thouſand five hundred ſixty pounds; the laſt they divide into twenty-ſeven mudes, and the mude into four ſchepels. In Poland, the laſt is forty Bourdeaux buſhels, and weighs about four thouſand eight hundred Paris pounds. In Pruſſia, the laſt is a hundred and thirty-three Paris ſeptiers. In Sweden and Muſcovy, they meaſure by the great and little laſt; the firſt containing twelve barrels, and the ſecond half as many. See LAST. In Muſcovy, they likewiſe uſe the cheſſord, which is different in various places: that of Archangel is equal to three Rouen buſhels.

MEASURES, *Italian dry*. At Venice, Leghorn, and Lucca, they eſtimate their dry things on the foot of the ſtaro or ſtaio; the ſtaro of Leghorn weighs fifty-four pounds: a hundred and twelve ſtaros, and ſeven-eighths, are equal to the Amſterdam laſt. At Lucca, a hundred and nineteen ſtaros make the laſt of Amſterdam. The Venetian ſtaro weighs a hundred twenty-eight Paris pounds: the ſtaro is divided into four quarters. Thirty-five ſtaros, and one fifth, or a hundred and forty quarters, and four-fifths, make the laſt of Amſterdam. At Naples and other parts, they uſe the tomolo, or tomalo, equal to one-third of the Paris ſeptier. Thirty-ſix tomoli and a half make the carro: and a carro and a half, or fifty-four tomoli, make the laſt of Amſterdam. At Palermo, fifteen tomoli make the ſalma; and four mondili, the tomolo. Ten ſalmas and three-ſeventhe, or a hundred and ſeventy-one tomoli and three-ſevenths, make the laſt of Amſterdam.

MEASURES, *Flemiſh dry*. At Antwerp, &c. they meaſure by the vierttel; thirty-two and a half whereof make nineteen Paris ſeptiers. At Hamburgh, the ſchepel; ninety whereof make nineteen Paris ſeptiers.

MEASURES, *Spaniſh and Portugueſe dry*. At Cadiz, Bilbon, and St. Sebaſtian, they uſe the fanega; twenty-three whereof make the Nantes or Rochel tun, or nine Paris ſeptiers and a half: though the Bilboa fanega is ſomewhat larger, inſomuch that twenty-one fanegas make a Nantes tun. At Seville, &c. they uſe the anagoras, containing a little more than the Paris mine; thirty-ſix anagoras make nineteen Paris ſeptiers. At Bayonne, &c. the concha; thirty whereof are equal to nine Paris ſeptiers and an half. At Liſbon, the alquier a very ſmall *meaſure*, two hundred and forty wherefore make nineteen Paris ſeptiers, ſixty the Liſbon muid.

Engliſh dry or corn MEASURES.

Solid Inches

34½	Pint							
272¼	8	Gallon						
544½	16	2	Peck					
2178	64	8	4	Buſhel				
	128	16	8	2	Strike			
	265	32	16	4	2	Carnock or coom

The uſual MEASURE *of wood for firing*, is the CORD; four feet high, as many broad, and eight long; this is divided into two half-cords, called *ways*, and by the French *membrures*, from the pieces ſtuck upright to bound them; or *voyes*, as being ſuppoſed half a waggon-load.

The MEASURE *for horſes* is the HAND, or handful; which by the ſtatute contains four inches.

MEASURE is alſo uſed to ſignify the cadence and time obſerved in poetry, dancing, and muſic, to render them regular and agreeable.

The different *meaſures* or metres, in poetry, are the different manners of ordering and combining the quantities, or the long and ſhort ſyllables. Thus hexameter, pentameter, iambic, ſapphic, verſes, &c. conſiſt of different *meaſures*.

In Engliſh verſes, the *meaſures* are extremely various and arbitrary, every poet being at liberty to introduce any new form that he pleaſes. The moſt uſual are, the heroic, generally conſiſting of five long, and five ſhort ſyllables; and verſes of four feet; and of three feet and a cæſura, or ſingle ſyllable.

The ancients, by variouſly combining and tranſpoſing their quantities, made a vaſt variety of different *meaſures*. Of words, or rather feet, of two ſyllables, they formed a ſpondee, conſiſting of two long ſyllables; a pyrrhic, of two ſhort ſyllables; a trochee, of a long and a ſhort ſyllable; and an iambic, of a ſhort and a long ſyllable.

Of their feet of three ſyllables, they formed a moloſſus, conſiſting of three long ſyllables; a tribrach, of three ſhort ſyllables; a dactyl, of one long, and two ſhort ſyllables; and an anepæſt, of two ſhort and one long ſyllable.

The Greek poets contrived a hundred and twenty-four different combinations or *meaſures*, under as many different names, from feet of two ſyllables to thoſe of ſix.

MEASURE, in *Muſic*, the interval, or ſpace of time, which the perſon, who beats time, takes between the raiſing and falling of his hand or foot, in order to conduct the movement, ſometimes quicker, and ſometimes ſlower, according to the kind of muſic, or the ſubject that is ſung or played.

The *meaſure* is that which regulates the time we are to dwell on each note. See TIME.

The ordinary or common *meaſure* is one ſecond, or ſixtieth part of a minute, which is nearly the ſpace between the beats of the pulſe or heart; the ſyſtole, or contraction of the heart, anſwering to the elevation of the hand; and its diaſtole, or dilatation, to the letting it fall. The *meaſure* uſually takes up the ſpace that a pendulum, of two feet and an half long, employs in making a ſwing or vibration. The *meaſure* is regulated according to the different quality or value of the notes in the piece; by which the time, that each note is to take up, is expreſſed. The ſemi-breve, for inſtance, holds one riſe, and one fall; and this is called the *meaſure*, or *whole meaſure*; ſometimes the *meaſure-note*, or *time-note*; the minim, one riſe, or one fall; and the crotcher, half a riſe, or half a fall, there being four crotchets in a full *meaſure*.

MEASURE, *binary or double*, is that wherein the riſe and fall of the hand are equal.

MEASURE, *ternary or triple*, is that wherein the fall is double to the riſe; or where two minims are played during a fall, and but one in a riſe. To this purpoſe, the number 3 is placed at the beginning of the lines, when the *meaſure* is intended to be triple; and a C, when the *meaſure* is to be common or double. This riſing and falling of the hands was called by the Greeks ἄρσις and θέσις. St. Auguſtine calls it *plauſus*, and the Spaniards *compas*. See ARSIS and THESIS.

MEASURES, *powder*, in *Artillery*, are made of copper, and contain from an ounce to twelve pounds: theſe are very convenient in a ſiege, when guns or mortars are loaded with looſe powder, eſpecially in ricochet firing, &c.

MEASURING, MENSURATION, defined *geometrically*, is the aſſuming any certain quantity, and expreſſing the proportion of other ſimilar quantities to the ſame.

MEASURING, defined *popularly*, is the uſing a certain known meaſure, and determining thereby the preciſe extent, quantity, or capacity of any thing.

Meaſuring, in the general, makes the practical part of GEOMETRY. From the various ſubjects whereon it is employed, it acquires various names, and conſtitutes various arts. Thus

MEASURING *of lines*, or quantities of one dimenſion, we call LONGIMETRY; and when thoſe lines are not extended parallel to the horizon, ALTIMETRY. When the different altitudes of the two extremes of the line are alone regarded, we call it LEVELLING.

MEASURING *of superficies*, or quantities of two dimensions, is variously denominated, according to its subjects: when conversant about lands, it is called GEODESIA, or SURVEYING: in other cases, it is called simply *measuring*. The inſtruments uſed are the ten-foot rod, chain, compaſs, circumferentor, &c.

MEASURING *of ſolids*, or quantities of three dimenſions, we call STEREOMETRY; where it is converſant about the capacities of veſſels, or the liquors they contain particularly, GAUGING.

The inſtruments for this are the gauging-rod, ſliding-rule, &c.

From the definition of *meaſuring*, where the *meaſure* is expreſſed to be ſimilar or homogeneous to, i. e. of the ſame kind with the thing meaſured, it is evident, that in the firſt caſe, or in quantities of one dimenſion, the *meaſure* muſt be a line; in the ſecond, a ſuperficies; and in the third, a ſolid. For a line, v. gr. cannot *meaſure* a ſurface; to *meaſure*, being no more than to apply the known quantity to the unknown, till the two become equal. Now a ſurface has breadth, and a line has none: and if one line have no breadth, two or a hundred have none. A line, therefore, can never be applied ſo often to a ſurface, as to be equal to it, i. e. to *meaſure* it. And from the like reaſoning it is evident, a ſuperficies, which has no depth, cannot become equal to, i. e. cannot *meaſure*, a ſolid, which has.

While a line continues ſuch, it may be meaſured by any part of itſelf: but when the line begins to flow, and to generate a new dimenſion, the *meaſure* muſt keep pace, and flow too; i. e. as the one commences ſuperficies the other muſt do ſo too. Thus we come to have *ſquare meaſures*, and *cubic meaſures*.

Hence we ſee why the *meaſure of a circle* is an arch, or part of the circle; for a right line can only touch a circle in one point, but the periphery of a circle conſiſts of infinite points. The right line therefore, to meaſure the circle, muſt be applied infinite times, which is impoſſible.

Again, the right line only touches the circle in a mathematical point; which has no parts or dimenſions, and has conſequently no magnitude; but a thing that has no magnitude or dimenſions, bears no proportion to another, that has; and cannot therefore meaſure it. Hence we ſee the reaſon of the diviſion of circles into 360 parts or arches, called *degrees*. See ARCH, CIRCLE, and DEGREE.

MEASURING *triangles*, or from three given ſides or angles, to determine all the reſt, is called TRIGONOMETRY.

MEASURING *of the air*, its preſſure, ſpring, &c. is called AEROMETRY, or PNEUMATICS.

MEAT, *cibus*. See FOOD.

MEATS, *dreſſing of*. See DRESSING.

MEATS, *dry*. See XEROPHAGY.

MEATS, *white*. See WHITE.

MEATUS *auditorius*, the entrance of the EAR; that is a cartilaginous ſubſtance, irregularly divided with fleſhy membranous interpoſitions in ſeveral parts of it, not unlike the bronchi in the lungs, only that the fleſhy fibres are here thicker. The inner part, or that next the brain, is bony. It is lined throughout with a thin membrane, derived from the ſkin, which is continued on the membrana tympani, where it becomes thinner. See *Tab. Anat. Oſteol.* *fig.* 14. *lit. f.*

From the beginning of the *meatus*, almoſt half-way, ariſe a great number of ſmall hairs, at whoſe roots iſſues the ear-wax, which is entangled in thoſe hairs, the better to break the impetus of the external air, and prevent its too ſuddenly ruſhing in on the membrana tympani.

MEATUS *cyſticus*. See CYSTICUS *Ductus*.

MEATUS *urinarius*, or *urinary paſſage*, in women, is very ſhort, lined internally with a very thin membrane; next to which is a coat of a white ſubſtance. Through this coat, from ſome lacunæ in it, paſs ſeveral ducts, which convey a limpid glutinous matter, ſerving to anoint the extremity of the urethra. See *Tab. Anat. Splanch.* *fig.* 9 *litt. r fig.* 11. *lit. b.*

MEE, or *Sea*-MEE, in *Ornithology*, the name of a water-bird of the larus or GULL-kind, which is all over of a duſky grey on its upper part; its head is blackiſh at the top, and the beak is red; the legs are ſhort and black, and the wings very long, reaching beyond the tail when folded.

MECAXOCHITL, in the *Materia Medica*, the name of the *piper longum hondſuri*, or ſmall American long pepper.

MECHANICS, MECHANICA, MECHANIC, a mixed mathematical ſcience, which conſiders motion, and moving powers, their nature and laws, with the effects thereof, in machines, &c. It is diſtinguiſhed by Sir Iſaac Newton into practical and rational *mechanics*: the former treats of the *mechanical* powers and of their various combinations: rational *mechanics* comprehends the whole theory of motion, and ſhews when the powers or forces are given, how to determine the motions that are produced by them; and *vice verſa*.

That part of *mechanics*, which conſiders the motion of bodies ariſing from gravity, is by ſome called STATICS—in diſtinction from that part which conſiders the *mechanical* powers, and their application, and which is properly called *mechanics*. See MECHANICAL *Powers*.

The term *mechanics* has of old been, and ſtill is, uſed in a double ſenſe in very different ſciences, both with reſpect to their objects and principles. For the name *mechanics* is applied equally to that ſcience which treats of the equilibrium and compariſon of powers; and to that ſcience in which the nature, generation, and alteration of motion are explained. To avoid ambiguity, therefore, it would be proper to give the name *ſtatics* to the ſcience of the equilibrium and compariſon of powers, and to reſtrain the term *mechanics* to the ſcience of motion.

Theſe two ſciences not only differ as to their objects and principles, but alſo with reſpect to the times in which they have been cultivated. Some of the principles of *ſtatics* were eſtabliſhed by Archimedes; but Galileo laid the firſt foundation of *mechanics*, when he inveſtigated the deſcent of heavy bodies; and ſince his time, by the aſſiſtance of the new methods of computation, a great progreſs has been made, particularly by Sir Iſaac Newton, in his Principia. This admirable work is now rendered more acceſſible to beginners by the learned comment of the fathers le Seur and Jacquier, printed, with the text, at Geneva, 1739, 4to. 1742, 3 vols. 4to. We have alſo the ſciences of ſtatics and *mechanics* treated of under the name of Phoronomia, by the late learned profeſſor Herman. Amſt. 1716, 4to. Mr. Euler's *Mechanica, ſive de Motus Scientia*, is ſufficiently recommended by the name of the author, well known as one of the moſt eminent mathematicians in Europe. This work, however, did not eſcape the cenſure of a late ingenious writer; but, granting the juſtneſs of his remarks, it may be ſaid, that a few inaccurate expreſſions, owing to analogies carried too far, and to the ſtyle of infinitiſimals, are but ſmall flaws in ſuch a work. As to ſtatics, the ſubject has been almoſt exhauſted by Varignon, in his Mecanique, Paris, 1725, 2 vol. 4to.

The doctrine of machines or engines is a principal branch of *mechanics*; but has not as yet been treated as it deſerves. We ſhall here inſert a few obſervations on this uſeful ſubject, from a late eminent author.

In treating of machines, we ſhould conſider the weight that is to be raiſed, the power by which it is to be raiſed, and the inſtrument or engine by which this effect is to be produced. There are two principal problems that ought to be reſolved in treating of each of them.

The firſt is, to determine the proportion which the power and weight ought to have to each other, that they may juſt ſuſtain one another, or be in æquilibrio.

The ſecond is, to determine what ought to be the proportion of the power and weight to each other, in a given machine, that it may produce the greateſt effect poſſible, in a given time.

All the writers on *mechanics* treat of the firſt of theſe problems, but few have conſidered the ſecond, though equally uſeful with the other.

As to the firſt problem, this general rule holds in all powers: ſuppoſe the engine to move, and reduce the velocities of the power and weight to the reſpective directions in which they act; find the proportions of thoſe velocities; then if the power be to the weight, as the velocity of the weight is to the velocity of the power; or, which amounts to the ſame thing, if the power multiplied by its velocity, gives the ſame product as the weight multiplied by its velocity, this is the caſe wherein the power and weight ſuſtain each other, and are in æquilibrio; ſo that in this caſe, the one would not prevail over the other, if the engine was at reſt; and if it is in motion, it would continue to proceed uniformly, if it were not for the friction of its parts, and other reſiſtances.

The ſecond general problem in *mechanics*, is, to determine the proportion which the power and weight ought to bear to each other, that when the power prevails, and the machine is in motion, the greateſt effect poſſible may be produced by it in a given time. It is manifeſt, that this is an enquiry of the greateſt importance, though few have treated of it. When the power is only a little greater than that which is ſufficient to ſuſtain the weight, the motion is too ſlow; and though a greater weight is raiſed in this caſe it is not ſufficient to compenſate the loſs of time. When the weight is much leſs than that which the power is able to ſuſtain, it is raiſed in leſs time; and this may happen not to be ſufficient to compenſate the loſs ariſing from the ſmallneſs of the load. It ought, therefore, to be determined when the product of the weight, multiplied by its velocity, is the greateſt poſſible; for this product meaſures the effect of the engine in a given time,

which

which is always the greater in proportion as the weight which is raiſed is greater, and as the velocity with which it is raiſed is greater. We ſhall therefore ſubjoin ſome inſtances of this kind, that may be demonſtrated from the common elementary geometry; wiſhing that further improvements may be made in this moſt uſeful part of *mechanics*.

When the power prevails, and the engine begins to move, the motion of the weight is at firſt gradually accelerated. The action of the power being ſuppoſed invariable, its influence in accelerating the motion of the weight decreaſes, while the velocity of the weight increaſes. Thus the action of a ſtream of water, or air, upon a wheel, is to be eſtimated only from the exceſs of the velocity of the fluid above the velocity already acquired by the part of the engine which it ſtrikes, or from their relative velocity. On the other hand, the weight of the load that is to be raiſed, and the friction, tend to retard the motion of the engine; and when theſe forces, viz. thoſe that tend to accelerate it, and thoſe that tend to retard it, become equal, the engine then proceeds with the uniform motion it has acquired.

Let A B (*Tab.* IV. *Mechanics*, *fig.* 50.) repreſent the velocity of the ſtream, A C, the velocity of the part of the engine which it ſtrikes, when the motion of the machine becomes uniform; and C B will repreſent their relative velocity, upon which the effect of the engine depends. It is known that the action of a fluid, upon a given plane, is as the ſquare of this relative velocity; conſequently the weight raiſed by the engine, when its motion becomes uniform, being equal to this action, it is likewiſe as the ſquare of C B. Let this be multiplied by A C, the velocity of the part of the engine impelled by the fluid; and the effect of the engine in a given time will be proportional to $AC \times CB^2 =$ (ſuppoſing C B to be biſected in D) $AC \times 2CD \times 2DB = 4AC \times CD \times DB$; conſequently, the effect of the engine is greateſt when the product of AC, CD, and DB is greateſt. But it is eaſy to ſee, that this product is greateſt, when the parts A C, C D, and D B, are equal; for if you deſcribe a ſemicircle upon A D, and the perpendicular C E meet the circle in E, then $AC \times CD = CE^2$; and is greateſt, when C is the centre of the circle; ſo that in order that $AC \times CD \times DB$ may be the greateſt poſſible, A D muſt be biſected in C; and C B having been biſected in D, it follows, that AC, C D, D B, muſt be equal; or that A C, the velocity of the part of the engine impelled by the ſtream, ought to be but one third of A B, the velocity of the ſtream. In this caſe, when (abſtracting from friction) the engine acts with the utmoſt advantage; the weight raiſed by it is to the weight that would juſt ſuſtain the force of the ſtream, as the ſquare of C B, the relative velocity of the engine and ſtream, to the ſquare of A B, which would be the relative velocity, if the engine was quieſcent; that is, as 2×2 to 3×3, or 4 to 9. Therefore, that the engine may have the greateſt effect poſſible, it ought to be loaded with no more than $\frac{4}{9}$ of the weight, which is juſt able to ſuſtain the efforts of the ſtream. See Mac Laurin's Account of Sir Iſaac Newton's Diſcov. p. 171. and Fluxions, art. 908.

Again, ſuppoſe that a given weight P, (*fig.* 51.) deſcending by its gravity in the vertical line, raiſes a greater weight W, likewiſe given, by the rope P M W (that paſſes over the fixed pulley M) along the inclined plane B D, the height of which B A is given; and let it be required to find the poſition of this plane, along which W will be raiſed in the leaſt time, from the horizontal line A D to B. Let B C be the plane upon which if W was placed, it would be exactly ſuſtained by P; in which caſe, P is to W as A B to B C. But W is to the force with which it tends to deſcend along the plane B D, as B D to A B; conſequently the weight P is to that force, as B D to B C. Therefore the exceſs of P above that force (which exceſs is the power that accelererates the motion of P and W) is to P, as B D − B C to B D; or taking B H upon B C equal to B D, as C H to B D. But it is known that the ſpaces deſcribed by motions uniformly accelerated, are in the compound ratio of the forces which produce them and the ſquares of the times; or, that the ſquare of the time is directly as the ſpace deſcribed in that time, and inverſely as the force; conſequently, the ſquare of the time, in which B D is deſcribed by W, will be directly as B D, and inverſely as $\frac{CH}{BD}$, and will be leaſt when $\frac{BD^2}{CH}$ is a minimum; that is, when $\frac{BC^2}{CH} + CH + 2BC$, or (becauſe 2 BC is invariable) when $\frac{BC^2}{CH} + CH$, is a minimum.

Now as when the ſum of two quantities is given, their product is a maximum when they are equal to each other; ſo it is manifeſt, that, when their product is given, their ſum muſt be a minimum, when they are equal. Thus it is evident, that as in *fig.* 50. the rectangle or product of the equal parts A C and C D was equal to CE^2; ſo the rectangle of any two unequal parts, into which A D may be divided, is leſs than CE^2, and AD, is the leaſt ſum of any two quantities, the product of which is equal to CE^2. But the product of $\frac{BC^2}{CH}$ and C H is BC^2, and conſequently given: therefore the ſum of $\frac{BC^2}{CH}$ and C H is leaſt, when theſe parts are equal, that is, when C H is equal to B C, or B D equal to 2 B C. It appears, therefore, that when the power P and weight W are given, and W is to be raiſed by an inclined plane, from the level of a given point A to the given point B in the leaſt time poſſible; we are firſt to find the plane B C, upon which W would be ſuſtained by P, and to take the plane B D double in length of the plane B C; or we are to make uſe of the plane B D, upon which a weight that is double of W could be ſuſtained by the power P.

For another example, ſuppoſe a fluid, moving with the velocity and direction A C, (*fig.* 52.), ſtrikes the plane C E; and ſuppoſe that this plane moves parallel to itſelf in the direction C B, perpendicular to C A, or that it cannot move in any other direction. Then let it be required to find the moſt advantageous poſition of the plane C E, that it may receive the greateſt impulſe from the action of the fluid. Let A P be perpendicular to C E in P, draw A K parallel to C B, and let P K be perpendicular upon it in K, and A K will meaſure the force with which any particle of the fluid impels the plane E C, in the direction C B. For the force of any ſuch particle being repreſented by A C, let this force be reſolved into A Q parallel to E C, and A P perpendicular to it; and it is manifeſt, that the latter A P only has any effect upon the plane C E. Let this force A P be reſolved into the force A L perpendicular to C B, and the force A K parallel to it; then it is manifeſt, that the former, A L, has no effect in promoting the motion of the plane in the direction C B; ſo that the latter A K, only, meaſures the effort by which the particle promotes the motion of the plane C E in the direction C B. Let E M and E N be perpendicular to C A and C B, in M and N; and the number of particles, moving with directions parallel to A C, incident upon the plane C E, will be as E M. Therefore the effort of the fluid upon C E being as the force of each particle, and the number of particles together, it will be as $AK \times EM$; or, becauſe A K is to A P (= E M,) as E N to C E, as $\frac{EM \times EN}{CE}$; ſo that C E being given, the problem is reduced to this, to find when $EM \times EN$ is the greateſt poſſible or a maximum. But becauſe the ſum of EM^2 and of EN^2 (= CM^2) is given, being always equal to CE^2, it follows that $EN^2 \times EM^2$, is greateſt, when $EN^2 = \frac{1}{2} CE^2$; in the ſame manner as it was demonſtrated above, that when the ſum of A C and C B (*fig.* 50.) was given, $AC \times CB^2$ was greateſt, when $AC = \frac{1}{3} AB$. But when $EN^2 \times EM^2$ is greateſt, its ſquare root $EN \times EM^2$ is of neceſſity at the ſame time greateſt. Therefore the action of the fluid upon the plane C E, in the direction C B, is greateſt when $EN^2 = \frac{1}{2} CE^2$, and conſequently $EM^2 = \frac{1}{2} CE^2$; that is, when E M, the ſine of the angle A C E, in which the ſtream ſtrikes the plane, is to the radius, as the $\sqrt{2}$ to $\sqrt{3}$; in which caſe it eaſily appears, from the trigonometrical tables, that this angle is of 54° 44'.

Several uſeful problems in *mechanics* may be reſolved by what was ſhewn in the preceding paragraph. If we repreſent the velocity of the wind by A C, a ſection of the ſail of a wind-mill perpendicular to its length by C E, as it follows from the nature of the engine, that its axis ought to be turned directly towards the wind, and the ſail can only move in a direction perpendicular to the axis, it appears, that when the motion begins, the wind will have the greateſt effect to produce this motion, when the angle A C E, in which the wind ſtrikes the ſail, is of 54° 44'. In the ſame manner, if C B repreſent the direction of the motion of a ſhip, or the poſition of her keel, abſtracting from her lee-way, and A C be the direction of the wind, perpendicular to her way, then the moſt advantageous poſition of the ſail C E, to promote her motion in the direction C B, is when the angle A C E, in which the wind ſtrikes the ſail, is of 54° 44'. The beſt poſition of the rudder, where it may have the greateſt effect in turning round the ſhip, is determined in like manner. And the ſame angle enters likewiſe into the determination of the figure of the rhombuſes that form the baſes of the cells in which the bees depoſit their honey, in the moſt frugal manner. See HONEY-*Comb*. But it is to be carefully obſerved, that when the ſine of the

the angle A C E is to the radius as $\sqrt{2}$ to $\sqrt{3}$; or, which is the same thing, when its tangent is to the radius, as the diagonal of a square to its side; this is the most advantageous angle only at the beginning of the motion of the engine; so that the sails of a common wind-mill ought to be so situated, that the wind may indeed strike them in a greater angle than that of 54°. 44'. For it is demonstrable, that when any part of the engine has acquired the velocity v, the effort of the wind upon that part will be greatest, when the tangent of the angle in which the wind strikes it is to the radius, not as the $\sqrt{2}$ to 1, but $\sqrt{2 \times \frac{9cc}{4aa} \times \frac{3c}{2a}}$ to 1, the velocity of the wind being represented by a. If, for example, $c = \frac{1}{2}a$; then the tangent of the angle A C E ought to be double of the radius; that is, the angle A C E ought to be of 63° 26'. If $c = a$; then A C E ought to be of 74° 19'. This observation is of the more importance, because, in this engine, the velocity of the parts of the sail remote from the axis, bears a considerable proportion to the velocity of the wind, and perhaps sometimes is equal to it; and because a learned author, Mr. Daniel Bernoulli, has drawn an opposite conclusion from his computations in his Hydrodynamics, by mistaking a minimum for a maximum; where he infers, that the angle in which the wind strikes the sail, ought to decrease as the distance from the axis of motion increases; that if $c = a$, the wind ought to strike in an angle of 45°; and that if the sail be in one plane, it ought to be inclined to the wind, at a medium, in an angle of 50°. How he fell into these mistakes is shewn by Mr. Mac Laurin, in his Fluxions, § 914.

In like manner, though the angle A C E of 54° 44' be the most advantageous at the beginning of the motion, when a ship sails with a side wind; yet it ought to be enlarged afterwards as the motion increases. In general, let A a, (*fig.* 52.) parallel to C B, be to A C, as the velocity which the engine has already acquired in the direction C B, to that of the stream; upon A C produced take A D to A C as 4 to 3, draw D G parallel to C B, and let a circle described from the centre C with the radius C a, meet D G in g; and the plane C E shall be in the most advantageous situation for promoting the motion of the engine, when it bisects the angle a C g.

It is generally supposed, that a direct wind always promotes the motion of a ship, the sail being perpendicular to the wind, more than any side-wind; and this has been affirmed in several late ingenious treatises; but, to prevent mistakes, we are obliged to observe, that Mr. Mac Laurin has demonstrated the contrary, in his Treatise of Fluxions, § 919; where other instances of this second general problem in *mechanics* are given, to which we refer. See Mac Laurin's Account of Sir Isaac Newton's Philosophical Discoveries, book ii. chap. 3. p. 173.

MECHANICAL, something that relates to *mechanics*, or is regulated by the nature and laws of motion.

In which sense we say, *mechanical* powers, *mechanical* properties of affections, *mechanical* principles, reasoning, knowlege, &c.

MECHANICAL *affections* are such properties in matter, as result from their figure, bulk, and motion.

MECHANICAL *causes* are those founded on such affections.

MECHANICAL *force*. See FORCE.

MECHANICAL *solutions* are accounts of things on the same principles.

MECHANICAL *philosophy* is the same with what we otherwise call the *corpuscular philosophy*; *viz.* that which explains the phenomena of nature, and the operations of corporeal things, on the principles of *mechanics*; viz. the motion, gravity, figure, arrangement, disposition, greatness, or smallness of the parts which compose natural bodies. See CORPUSCULAR.

MECHANIC, or MECHANICAL *powers* (so called), are those machines which are used for raising greater weights, or overcoming greater resistances than could be effected by the natural strength without them; the power or strength being applied to one part of the machine, and another part of the machine applied to the weight or resistance.

The simple machines whereby power is gained, are six in number, viz. the LEVER, the *wheel and axle* or AXIS *in peritrochio*, the PULLEY (or rather system of pullies), the *inclined* PLANE, the WEDGE, and the SCREW. Of these, all sorts of mechanical engines do consist: and in treating of them, so as to settle their theory, we must consider them as mathematically exact, and moving without friction. Although these machines are treated of at large under their proper heads, it may not be amiss to give a short account of them all here.

1. A *lever* is an inflexible bar, turning upon a supporting prop as its center or motion, which must be firm enough to bear the lever and the weight with which it is charged. There are three kinds of levers, and in each of them the velocity of each *point* is directly as its distance from the prop.

A lever is said to be of the first kind when the prop is between the weight and the power. Here, the power and weight balance each other, when the power is in proportion to the weight as the distance of the weight from the prop is to the distance of the power from it, so that, if a weight be twenty pounds, and at one foot from the prop, a power of one pound at twenty feet from the prop will balance the weight, supposing the lever itself to have no weight. To this sort of lever may be reduced all iron crows, scissars, pluchers, candle-snuffers, and the like.

A lever is said to be of the second kind, when the weight is between the prop and the power. Here the lever and weight balance each other when the power is in proportion to the weight as the distance of the weight from the prop is to the distance of the power from it. Of this sort are doors turning on hinges, oars, and such knives as are fixed at the point.

A lever is said to be of the third kind when the power is between the weight and the prop. In this, the power and weight balance each other, when the power is in proportion to the weight, as the distance of the weight from the prop is to the distance of the power from it: but this lever is never used where power is wanted to be gained; for in it, the intensity of the power applied, must always exceed the intensity of the weight to be raised, or resistance to be overcome. Of this sort are the bones of our legs and arms, and the wheels of clocks and watches.

2. In the *wheel and axle*, where the power is applied to the wheel, and the weight drawn up by a rope winding round the axle, the velocity of the power is to the velocity of the weight, as the circumference of the wheel is to the circumference of the axle, and the advantage gained by the machine is in the same proportion: for the power and weight balance each other when the power is in proportion to the weight, as the circumference of the axle is to the circumference of the wheel. See *Tab. Mech. fig.* 7. This machine is the principal part of a common *crane*.

3. A *pulley*, that only turns on its axis, and does not rise with the weight, serves only to change the direction of the power; for it gives no mechanical advantage thereto. But when, besides the upper pullies, which turn round in a fixed frame, or block, there is a block of pullies moving equally fast with the weight, the velocity of the weight is to the velocity of the power as one is to twice the number of pullies in the moveable block: and the power and weight balance each other when the power is in proportion to the weight, as one is to twice the number of pullies in the moveable block.

4. An *inclined* PLANE is like one half of a wedge which has been cut in two equal parts lengthwise. A weight raised, or a resistance moved, by an inclined plane, moves only through a space equal to the height of that machine, in the time that the power drives it through a space equal to its whole length. Therefore, the velocity of the power is in proportion to the velocity of the weight, as the length of the machine is to its thickness or height at the back: and the power and weight balance each other when the power is in proportion to the weight, as the thickness of the plane is to its length. All edge tools, which are chamfered (or ground down only on one side to the edge) are inclined planes, as far as the chamfer goes from the edge.

5. A *wedge*, in the common form, is like two inclined planes, joined together at their bases; and the thickness of these planes (opposite their sharp edges) make the back of the wedge, to which the power of the sledge or hammer is applied in cleaving of wood.

When two equal resistances act perpendicularly against opposite sides of the wedge, and a power acts perpendicularly against the back of the wedge, the velocity of the power is in proportion to the velocity of the resistance, on either side, as the length of the side is to half the thickness of the back: and the power balances the resistance of the wood, when the power is in proportion to the resistance, as half the thickness of the back of the wedge is to the length of either of its sides, if the sharp edge goes to the bottom of the cleft in the wood. But when the wood splits before the wedge, as it generally does, the power balances the resistance, when the former is to the latter as half the thickness of the wedge (when it is driven quite into the wood) is to the whole length of the cleft below the back of the wedge.

6. The *screw* may be considered as if it were an inclined plane, wrapt round a cylinder. In this machine, the power must turn the cylinder quite round, in the time that the weight or resistance (as in a common press) moves through a space equal to the distance between the threads or spirals of the screw. Therefore, the velocity

of

of the power is in proportion to the velocity of the weight or refiſtance, as the circumference of a circle, deſcribed by the power, is to the diſtance between the ſpirals of the ſcrew: and the power and reſiſtance balance each other, when the former is to the latter as the diſtance between the ſpirals is to the circumference of the circle deſcribed by the power. This machine, beſides the advantage peculiar to itſelf, has generally the benefit of the wheel and axle, on account of the winch or lever by which it is turned.

Of theſe ſix ſimple machines, all the moſt compound engines in the world are made. As the ſcrew includes the inclined plane, and two equally inclined planes make the wedge, we have all the mechanical powers combined together in a common *jack*, if it be turned by the fly; for then we have alſo the lever, the wheel and axle, and the pullies.

Thus, in a frame A B C D, *Tab.* IV. *Mechanics*, *fig.* 53. faſtened by the nut O upon the ſtand O O, and held together by the pillars V W and B *q*, is adapted firſt the piece E F, whoſe fans or flies may be put in motion by the wind, or drawn by a hair faſtened at F, which repreſents the lever and balance: at right angles to this piece is joined the perpendicular ſpindle G H having upon it the endleſs ſcrew H, which may be alſo conſidered as a wedge. This endleſs ſcrew or worm takes the ſkew teeth of the wheel K, which is the axis in peritrochio, and, in turning round, winds up the ſtring L M upon its axis, which paſſing round the pullies at M and N, or drawing by a tackle of five, raiſes the weight P. But as the ſcrew has no progreſſive motion on its axis, it cannot here be ſaid to comprehend the inclined plane; therefore, in order to make this machine take in all the *mechanical* powers, we may add the inclined plane, *r q* Q R, by making it reſt on the ground at Q R, and on the pillar *q* B, at *q r*, and thereby the force of the power drawing at F, will be farther increaſed in the proportion of Q T to T S. The whole force gained by this machine is found by comparing the ſpace gone through by the point F, with the height through which the weight is raiſed, in any determinate number of revolutions of F. A hundred pounds weight at P will be eaſily raiſed by the hair of a man's head drawing at F.

If an engine conſtructed in this manner be uſed for raiſing a weight, by means of a power applied to the fly, the power will balance the weight, if it be in proportion to the weight as the velocity of the weight is to the velocity of the fly. Now, conſidering how faſt the fly moves with reſpect to the motion of the weight, it is evident, that a crane, conſtructed in the manner of a common jack, would be an engine of very great power. But then the time loſt in raiſing the weight would alſo be very great: for, in any machine or engine whatever, the time loſt in working it will be as great as the power gained by it.

If machines or engines could be made without friction, the leaſt degree of power added to that which balances the weight, would be ſufficient to raiſe it. In the lever, the friction is next to nothing; in the wheel and axle it is but ſmall; in the pullies it is very conſiderable; and in the inclined plane, wedge, and ſcrew, it is very great. The univerſal law or principle in all *mechanical* machines or engines, made to gain power, is, that the power gained will be always as great as the velocity of the power exceeds the velocity of the weight or reſiſtance: and, upon this principle, it is eaſy to compute the power, force, or advantage, of any ſimple machine or compound engine, whatever.

E. gr. If the body A (*Tab. Mechanics*, *fig.* 6.) be triple the body B, and each of them be ſo fixed to the extremities of a lever A B, whoſe fulcrum, or fixed point is C, as that the diſtance of B C be triple the diſtance C A; the lever cannot be inclined on either ſide, but the ſpace B E, paſſed over by the leſs body, will be triple the ſpace A D, paſſed over by the great one. So that their motions or moments will be equal, and the two bodies in equilibrio.

Hence that noble challenge of Archimedes, *date ubi conſtem, totum ſpecies movere*; for as the diſtance C B may be increaſed infinitely, the power or moment of A may be increaſed infinitely. So that the whole of *mechanics* is reduced to the following problem.

Any body, as A, with its velocity C, *and alſo any other body, as* B, *being given; to find the velocity neceſſary to make the moment, or quantity of motion, in* B, *equal to the moment of* A, *the given body.* Here, ſince the moment of any body is equal to the rectangle under the velocity, and the quantity of matter; as B : A :: C : to a fourth term, which will be , the celerity proper to B, to make its moment equal to that of A. Wherefore in any machine or engine, if the velocity of the power be made to the velocity of the weight, reciprocally as the weight is to the power; ſuch power will always ſuſtain, or, if the power be a little increaſed, it will move the weight.

Let, for inſtance, A B be a lever, whoſe fulcrum is at C, and let it be moved into the poſition *a* C *b*. Here, the velocity of any point in the lever is as the diſtance from the centre. For let the point A deſcribe the arch A *a*, and the point B the arch B *b*; then theſe arches will be the ſpaces deſcribed by the two motions: but ſince the motions are both made in the ſame time, the ſpaces will be as the velocities. But it is plain, the arches A *a* and B *b* will be to one another, as their radii A C and C B, becauſe the ſectors A C *a*, and B C *b*, are ſimilar: wherefore the velocities of the points A and B are as their diſtances from the centre C.

Now, if any powers be applied to the ends of the lever A and B, in order to raiſe its arms up and down; their force will be expounded by the perpendiculars S *a*, and *b* N; which, being as the right lines of the former arches, *a* A and *b* B, will be to one another alſo as the radii A C and C B; wherefore the velocities of the powers are alſo as their diſtances from the centre. And ſince the moment of any body is as its weight, or gravitating force, and its velocity, conjunctly; if different powers or weights be applied to the lever, their moments will always be as the weights and the diſtances from the centre conjunctly. Wherefore, if to the ſame lever there be two powers or weights applied reciprocally proportional to their diſtances from the centre, their moments will be equal; and if they act contrarily, as in the caſe of a ſteelyard, the lever will remain in an horizontal poſition, or the balance will be in equilibrio. And thus it is eaſy to conceive how the weight of one pound may be made to equibalance a thouſand, &c.

Hence alſo it is plain, that the force of the power is not at all increaſed by engines; only the velocity of the weight in either lifting or drawing is ſo diminiſhed by the application of the inſtrument, as that the moment of the weight is not greater than the force of the power. Thus, for inſtance; if any force can raiſe a pound weight with a given velocity, it is impoſſible by any engine to effect, that the ſame power ſhall raiſe two pound weight with the ſame velocity: but by an engine it may be made to raiſe two pound weight, with half the velocity; or 1000 times the weight with $\frac{1}{1000}$th of the former velocity.

We ſhall here introduce into one view, an account of the principal methods that have occurred to us of explaining and demonſtrating the fundamental property of the ſeveral *mechanical* powers. It has been already obſerved, that, with regard to the lever, when any two forces act againſt each other on its arms, they will continue in equilibrio, if their quantities are inverſely as the diſtances between the points to which they are applied, and the point or fulcrum round which the lever turns. The demonſtration commonly aſcribed to Archimedes, is founded upon this principle, that when any cylindric or priſmatic body is applied upon a lever, it has the ſame effect as if its whole weight was united and applied at the middle point of its axis. Let A B, *Tab.* IV. *Mechanics*, *fig.* 54. be a cylinder, of an uniform texture, C its middle point; and it is manifeſt, that if the point C be ſupported, the equal halves of the cylinder, C A and C B, will balance each other about the point C, and the body will remain in equilibrio. Let the cylinder A B be diſtinguiſhed into any unequal parts, A D and D B; biſect A D in E, and D B in F; then a power applied at E, equal to the weight of the part A D, with a contrary direction, will ſuſtain it; and a power applied at F, equal to the weight of the part D B, with a contrary direction, will ſuſtain that part; ſo that theſe two powers acting at E and F, reſpectively equal to the weights of A D and D B, have preciſely the ſame effect as a prop at C, ſuſtaining the whole cylinder A B, and may be conſidered as in equilibrio with a power, acting at C, equal to the whole weight of the cylinder. But the diſtance C E = C A — A E = ½ A B — ½ A D = ½ D B; and, in like manner, the diſtance C F = C B — B F = ½ A B — ½ D B = ½ A D; conſequently C E is to C F as D B to A D; that is, as the power applied at F to the power applied at E, theſe being in equilibrio with the weight of the whole cylinder applied at C. From which it appears, that powers applied at E and F, which are to each other in the proportion of C F to C E, ſuſtain one another about the centre C.

It has been objected by M. Huygens, and others, to this demonſtration of Archimedes, that, when the whole cylinder is diſtinguiſhed into two ſegments, part of the weight of the greater ſegment acts on the ſame ſide of the fulcrum with the leſſer ſegment; and, therefore, when the whole weight of the greater ſegment is contracted into its middle point on one ſide of the fulcrum, and acts altogether againſt the leſſer ſegment, it requires ſome proof to ſhew, that this contracted weight will be

balanced by the weight of the leſſer ſegment. M. Huygens propoſed a method of his own, depending on a poſtulatum aſſumed in common with Archimedes, and needing demonſtration, viz. that when equal bodies are placed on the arms of a lever, the one which is fartheſt from the fulcrum will prevail and raiſe the other up.

Sir Iſaac Newton demonſtrates the fundamental propoſition concerning the lever, from the reſolution of motion: let C, *fig.* 55. be the centre of motion in the lever K L; let A and B be any two powers applied to it at K and L, acting in the directions K A and L B. From the centre of motion C, let C M and C N be perpendicular to thoſe directions in M and N; ſuppoſe C M to be leſs than C N, and from the centre C, at the diſtance C N, deſcribe the circle N H D, meeting K A in D. Let the power A be repreſented by D A, and let it be reſolved into the power D G acting in the direction C D, and the power D F perpendicular to C D, by completing the parallelogram A F D G. The power D G, acting in the direction C D from the centre of the circle, or wheel, D H N towards its circumference, has no effect in turning it round the centre, from D towards H, and tends only to carry it off from that centre. It is the part D F only that endeavours to move the wheel from D towards H and N, and is totally employed in this effort. The power B may be conceived to be applied at N as well as at L, and to be wholly employed in endeavouring to turn the wheel the contrary way, from N towards H and D. If therefore the power B be equal to that part of A which is repreſented by D F, their efforts, being equal and oppoſite, muſt deſtroy each other's effects; that is, when the power B is to the power A, as D F to D A, or (becauſe of the ſimilarity of the triangles A F D, D M C) as C M to C D or as C M to C N, then the powers muſt be in equilibrio; and thoſe powers always ſuſtain each other that are in the inverſe proportion of the diſtances of their directions from the centre of motion; or, when the product of the one power multiplied by the diſtance of its direction from the centre, is equal to the product of the power on the other ſide multiplied by the like diſtance from it.

Mr. Maclaurin propoſes a new method of demonſtrating the law of equilibrium in the lever, which ſeems, he ſays, to be founded on the plaineſt and moſt evident principles: theſe principles are the following, viz. that if equal powers act at equal diſtances on different ſides of the fulcrum or centre of motion, with directions oppoſite and parallel to each other, they will have the ſame effect: and that, if gravity be ſuppoſed to act in parallel lines, and the fulcrum be between the bodies, whoſe powers are eſtimated, it muſt bear the ſum of their weights; becauſe the lever being loaded with thoſe weights, it muſt give way if the fulcrum does not ſuſtain their ſum: but if the powers are on the ſame ſide of the fulcrum, in which caſe one of them muſt pull upwards whilſt the other pulls downwards, that there may be an equilibrium, it is then only loaded with the difference of the powers.

Suppoſing, therefore, firſt, two equal powers, A and B, *fig.* 56. acting in the directions A F, B H, to carry a body C, upon the lever A B, placed at C at equal diſtances from them; it is evident, that, in this caſe, each of the powers A and B ſuſtains one half of the weight C, by dividing it equally between them. Imagine now that the power A is taken away, and that inſtead of reſting upon it, the end A of the lever reſts upon a prop at A; it is manifeſt that the power B, and the prop at A, ſuſtain, as before, each one half of the weight C; the prop now acting, in every reſpect, as the power at A before; and, the equilibrium continuing, it appears, that in this caſe, a power B equal to one half of the weight C ſuſtains and balances it, when the diſtance of C from the prop A is one half of the diſtance of B from the ſame; that is, when B is to C, as C A to B A, or B × B A = C × C A. From this ſimple inſtance we ſee, that powers act upon a lever not by their abſolute force only, but that their effect neceſſarily depends upon the diſtance of the point where they act from the prop, or centre of motion; and particularly, that a power balances a double power which acts at half its diſtance from the prop, on the ſame ſide of it, with an oppoſite direction.

The caſe when the two powers act on different ſides of the prop, follows from this, by the principles already laid down. For let B H and C G (*fig.* 57.) repreſent the directions and forces with which the powers B and C act upon the lever; upon B A produced take A E equal to A C, or ½ A B, and in place of the power C G ſubſtitute an equal power E K at E, with an oppoſite direction; and, by the firſt of theſe principles, this power E K will have the ſame effect as C G, only the prop or centre of motion A will now ſuſtain the ſum of the forces E K and B H, by the ſecond of theſe principles. But the equilibrium between the powers B H and E K will continue as it was before, between B H and C G; ſo that the powers B H and E K will be in equilibrio, when the power B H is one half of E K, and the diſtance of E K from the prop A is one half of the diſtance of B H from the ſame; that is, when the power at B is to the power at E, as A E to A B, or B × B A = E × E A. In this caſe, the prop A being loaded with both the powers B and E which act with the ſame direction, its reaction muſt be equal to their ſum E K + B H = 3 B H, and muſt be in the oppoſite direction A F. In place of this reaction let us now (*fig.* 58.) ſubſtitute a power A F at A, equal to thrice B H; and in place of the power E K, let us ſubſtitute a prop at E, ſuſtaining that end of the lever B E; and ſince the equilibrium continues as before, it follows that the prop or centre of motion, being at E, the power B H ſuſtains the power A F which is triple of B H, when the diſtance of B H from the prop E is triple of the diſtance of the power A F from the ſame, that is, when B H × B E = A F × A E.

If we ſuppoſe the power E K to remain (*fig.* 59.) but the end B of the lever E B to reſt upon a prop, then the powers A F and E K will ſuſtain and balance each other, the prop at B now coming in place of the power B H; in which, A F = 3 B H, and E K = 1 B H; ſo that A F is to E K as 3 to 1; and the diſtances E B and A B being in the ſame proportion, it appears that when two powers in the proportion of 3 to 1 act upon a lever on the ſame ſide of the prop, or centre of motion, with oppoſite directions, at diſtances in the proportion of 2 to 3, they then ſuſtain each other. We have demonſtrated therefore, that when the powers are in the proportion either of 2 to 1, or of 3 to 1, or of 3 to 2, and the diſtances of their application from the centre of motion are in the inverſe proportion, then thoſe powers balance each other, or are in equilibrio.

Upon B E produced (*fig.* 60.) take E L = E A; and in place of the power A F ſubſtitute a power L M = A F, but with a contrary direction; this power L M will have the ſame effect to turn the lever round the centre of motion E as A F had; conſequently it will be in equilibrio with the power B H, as A F was. Therefore when two powers L M and B H in the proportion of 3 to 1, act upon a lever with the ſame direction, they are in equilibrio, if their diſtances from the centre of motion L E and E B be in the ratio of 1 to 3; that is, when L M × L E = B H × B E. In this caſe, the powers L M and B H acting with the ſame direction, the prop E muſt ſuſtain their ſum L M + B H = 4 B H, by the ſecond principle above premiſed. Therefore a power at L as 3, and a power acting at B with the ſame direction as 1, are ſuſtained by a power acting at E, with a contrary direction, as 4. From which it follows, by ſubſtituting in the place of the power L M a prop at L, that a power at B as 1 ſuſtains a power at E as 4, acting with a contrary direction, when B L is to E L as 4 to 1; that is, when the powers are inverſely as their diſtances from the prop, or centre of motion. By ſubſtituting the prop at B in the place of the power B H, it appears that a power L M at L, as 3, ſuſtains a power, acting with an oppoſite direction, at E, as 4, when their diſtances L B and E B from the prop B, are to each other as 4 to 3, or when L M × L B = E K × E B. By taking upon L B produced B *e* = B E, (*fig.* 61.) and in place of the power at E, ſubſtituting an equal power at *e* with a contrary direction, it appears, that a power at L as 3 ſuſtains a power acting at *e*, with the ſame direction, as 4, when the diſtance L B is to the diſtance *e* B, as 4 to 7. In this caſe, the prop at B ſuſtains the ſum of the powers acting at L and *e*, that is, a power equal to ſeven times B H. From which it follows, by ſubſtituting a prop at L, or *r*, in place of the powers that act there, that a power at *r* as 3 ſuſtains a power at B as 7, about the centre of motion L, when their diſtances from it *r* L, B L are to each other as 7 to 4: and that a power at L as 3 ſuſtains the power at B as 7, about the centre of motion *r*, when their diſtances from it, L *r* and B *r*, are to each other as 7 to 3.

By proceeding in this manner it appears, that when two powers are to each other as number to number, and when their diſtances from the centre of motion are in the inverſe ratio of the ſame numbers, then the powers ſuſtain each other, or are in equilibrio. From which it is eaſy to ſhew, in general, that when the powers are to each other in any ratio, though incommenſurable, and the diſtances of their application from the centre of motion in the ſame inverſe ratio, then they are in equilibrio; becauſe the ratio of incommenſurable quantities may be always limited to any degree of exactneſs at pleaſure between a greater and a leſſer ratio of number to number. To Mr. Maclaurin's demonſtration it has been objected, that it cannot be applied when the arms of

the lever are incommensurable, and as it cannot conclude generally, it muſt, therefore, be imperfect. Dr. Hamilton, having obſerved that theſe ſeveral methods of demonſtrating the fundamental property of the lever are liable to objections, propoſes a new proof, depending on the following poſtulatum, viz. If a force be uniformly diffuſed over a right line, ſo that an equal part of the force acts upon every point of the line, and if the whole force acts according to one and the ſame plane, this force will be ſuſtained, and the line kept in equilibrio, by a ſingle force applied to the middle point of the line equal to the diffuſed force, and acting in a contrary direction. He alſo premiſes this lemma; if a right line be divided into two ſegments, the diſtances between the middle of the whole line and the middle points of the ſegments, will be inverſely as the ſegments. This is ſelf-evident when the ſegments are equal; and, when they are unequal, ſince half of the whole line is equal to half of the greater and half of the leſſer ſegment, it is plain, that the diſtance between the middle of the whole line and the middle of one ſegment, muſt be equal to half of the other ſegment, ſo that theſe diſtances muſt be to each other inverſely as the ſegments.

Let the line G H, then, *fig.* 62. whoſe middle point is D, be divided into the unequal ſegments G L and L H, whoſe middle points are C and F, and let two forces or weights, A and B, which are to each other as the ſegments G L and L H, be applied to their middle points C and F, and let them act perpendicularly on the line G H: then (by the lemma) the weights A and B will be to each other inverſely as C D and F D (the diſtances of the points C and F, to which they are applied from the middle of the whole line); if then a third force or weight E, equal to the ſum of the forces A and B, be applied to the point D, and acts on the line in an oppoſite direction; I ſay theſe three forces will ſuſtain each other, and keep the line in equilibrio. For let us ſuppoſe the force E to be removed and inſtead of it another force, equal alſo to the ſum of A and B, to be uniformly diffuſed over the whole line G H, and to act directly againſt the forces A and B, then the part of this force which acts on the ſegment G L, will be equal to the force A, and therefore will be ſuſtained by it (poſtulatum); and the other part, which is diffuſed over the ſegment L H, will be equal to and ſuſtained by the force B, ſo that the forces A and B will ſuſtain this diffuſed force and keep the line in equilibrio. Let now two other forces act alſo on this line in oppoſite directions, one of them the force E acting on the point D, as it was firſt ſuppoſed to do, and the other an uniformly diffuſed force equal to E (and conſequently equal to the other diffuſed force), then theſe two additional forces will alſo balance each other, and therefore the equilibrium will ſtill remain. So that the two forces A and B, and a diffuſed force acting on one ſide of the line ſuſtain the force E, and a diffuſed force acting on the other ſide: but it is manifeſt, that in this equilibrium, the two diffuſed forces acting on oppoſite ſides are perfectly equivalent, and therefore if they are taken away from both ſides, the equilibrium muſt ſtill remain. Hence it appears that the three weights or forces A, B and E, any two of which are (by the conſtruction) to each other inverſely as their diſtances from the third, will ſuſtain each other and keep the line on which they act in equilibrio; which is the firſt and moſt ſimple caſe of the property of the lever: for here the directions of the weights are ſuppoſed to be perpendicular to the line on which they act, and it is evident that, if one of the points C, D, or F be fixed or conſidered as a fulcrum, the weights acting on the other two points will continue to ſupport each other. The ſecond caſe of the property of the lever is eaſily deduced from the firſt; for when two weights act on the arms of a lever in oblique directions, and are to each other inverſely as the perpendicular diſtances of the lines of direction from the centre of motion, then, by the reſolution of forces, it is eaſily proved that the parts of thoſe forces which act perpendicularly on the arms of the lever, and which only are exerted to turn the lever, are to each other inverſely as the lengths of thoſe arms; and therefore by the firſt caſe they muſt balance each other.

From what has been above demonſtrated, it appears, that the power with which any two forces move or endeavour to move the arms of a lever, are as the rectangles, under lines proportional to the forces, and the perpendicular diſtances of their lines of direction from the fulcrum: and alſo that when two bodies acting on the arms of a lever ſuſtain each other, if one of them be removed farther from the fulcrum, it will preponderate; but if it be brought nearer to the fulcrum, the other weight will prevail: becauſe the product to which its force is proportional will be increaſed in the firſt caſe, and diminiſhed in the ſecond.

When a weight is to be raiſed by means of an axle and wheel, it is faſtened to a chord that goes round the axle, and the power, which is to raiſe it, is hung to a chord that goes round the wheel. If then the power be to the weight as the radius of the axle to the radius of the wheel, it will juſt ſupport that weight; as will eaſily appear from what was proved of the lever. For the axle and wheel may be conſidered as a lever, whoſe fulcrum is a line paſſing through the centre of the wheel and middle of the axle, and whoſe long and ſhort arms are the radii of the wheel and axle which are parallel to the horizon, and from whoſe extremities the chords hang perpendicularly. And thus an axle and wheel may be looked upon as a kind of perpetual lever, on whoſe arms the power and weight always act perpendicularly, though the lever turns round its fulcrum. And in like manner when wheels and axles move each other by means of teeth on their peripheries, ſuch a machine is really a perpetual compound lever: and by conſidering it as ſuch, we may compute the proportion of any power to the weight it is able to ſuſtain by the help of ſuch an engine. And ſince the radii of two contiguous wheels, whoſe teeth are applied to each other, are as the number of teeth in each, or inverſely as the number of revolutions, which they make in the ſame time: we may, in the computation, inſtead of the ratio of theſe radii, put the ratio of the number of teeth on each wheel; or the inverſe ratio of the number of revolutions they make in the ſame time.

The moſt natural method of explaining the effects of the pulley, that is, of computing the proportion of any power to the weight it can ſuſtain by means of any ſyſtem of pullies is, by conſidering that every moveable pulley hangs by two ropes equally ſtretched, which muſt bear equal parts of the weight; and therefore when one and the ſame rope goes round ſeveral fixed and moveable pullies, ſince all its parts on each ſide of the pullies are equally ſtretched, the whole weight muſt be divided equally amongſt all the ropes by which the moveable pullies hang. And conſequently if the power which acts on one rope be equal to the weight divided by the number of ropes, or double the number of moveable pullies, that power muſt ſuſtain the weight.

The ſeveral caſes in which the wedge is applied may be comprehended in one general propoſition; let the equicrural triangle A B C, *fig.* 63. repreſent a wedge, the lines A B and C B will be the ſides of the wedge, A C its baſe or back, and its height will be the line P B biſecting the baſe A C and alſo the vertical angle A B C. When any two reſiſting forces act on the ſides of a wedge in directions which make equal angles with the ſides (as they are always ſuppoſed to do), a power acting perpendicularly at P on the baſe of the wedge will keep the reſiſting forces in equilibrio, when it is to the ſum of theſe forces, as the ſine of half the vertical angle of the wedge, to the ſine of the angle which the directions of the forces contain with the ſides of the wedge.

For let E and F be two bodies acting on the ſides of the wedge, and let them be firſt ſuppoſed to act in the directions E P and F P perpendicular to the ſides; then ſince the power P acts perpendicularly on the baſe A C, if theſe three forces keep the wedge in equilibrio, they will be to each other as the ſides of a triangle to which their directions are parallel, or (which is the ſame thing) as the ſides of the triangle A B C to which their directions are perpendicular. Therefore the power P is to the ſum of the reſiſting forces which it ſuſtains as A C the baſe of the wedge to the ſum of the ſides, or as P A, half the baſe, to A B one of the ſides; but P A is to A B as the ſine of P B A, half the vertical angle of the wedge, to the radius which is the ſine of a right angle, and the directions of the reſiſting forces are ſuppoſed in this caſe to contain a right angle with the ſides of the wedge.

Let now the reſiſting bodies E and F be ſuppoſed to act on the wedge in directions parallel to the lines D P and O P, which make oblique angles with its ſides, draw E G and F K perpendicular to thoſe lines. From what has been proved it appears that the power P is to the force with which it is able, by means of the wedge, to protrude the reſiſting bodies in the directions P E and P F, as the ſine of half the vertical angle to the radius, let this protruding force be expreſſed by the line P E, and let it be reſolved into two forces expreſſed by the lines P G and G E, the former of theſe only will act in oppoſition to the reſiſting bodies, therefore the whole protruding force of the power P to the force with which it acts againſt the reſiſting bodies E and F in the directions P D and P O as P E to P G, or (becauſe the triangles E P G and D P E are ſimilar) as P D to P E, that is as the radius to the ſine of the angle P D E; compounding therefore the ratio of the ſine of half the vertical angle to the radius, with the ratio of the radius to the ſine of the angle P D E, the power P, when the wedge is kept in equilibrio, will be to the force with which it protrudes the reſiſting bodies in directions oppoſite to thoſe in which they act, as the ſine of

half

half the vertical angle to the line of the angle PDE or POF, which the directions of the reſiſting forces conſiſt with the ſides of the wedge.

Hence, when the directions in which reſiſting bodies act on a wedge are given, we may eaſily find two lines that will expreſs the proportion between the reſiſtance and the power which ſuſtains it by means of the wedge. For from P, the middle point of the wedge, draw the line PD meeting one of the ſides, and parallel to the direction in which the reſiſting force acts on that ſide, then the power will be to the reſiſtance as PD to PB the height of the wedge. For PD and PB are to each other as the lines of the oppoſite angles, in the triangle PBD, that is as the lines of half the vertical angle, and the angle which the direction of the reſiſting force contains with the ſide of the wedge.

From what has been demonſtrated we may deduce the proportion of the power to the reſiſtance it is able to ſuſtain in all the caſes in which the wedge is applied. Firſt, when in cleaving timber the wedge fills the cleft, then the reſiſtance of the timber acts perpendicularly on the ſides of the wedge, therefore in this caſe, when the power which drives the wedge, is to the cohæſive force of the timber as half the baſe to one ſide of the wedge, the power and reſiſtance will be in equilibrio.

Secondly, when the wedge does not exactly fill the cleft, which generally happens becauſe the wood ſplits to ſome diſtance before the wedge: let ELF repreſent a cleft into which the wedge ABC is partly driven; as the reſiſting force of the timber muſt act on the wedge in directions perpendicular to the ſides of the cleft, draw the line PD in a direction perpendicular to EL the ſide of the cleft and meeting the ſide of the wedge in D; then the power driving the wedge and the reſiſtance of the timber, when they balance, will be to each other as the line PD to PB the height of the wedge.

Thirdly, when a wedge is employed to ſeparate two bodies that lie together on a horizontal plane, for inſtance two blocks of ſtone; as theſe bodies muſt recede from each other in horizontal directions, their reſiſtance muſt act on the wedge in lines parallel to its baſe CA; therefore the power which drives the wedge will balance the reſiſtance when they are to each other as PA half the breadth of the wedge to PB its height; and then any additional force ſufficient to overcome the reſiſtance ariſing from the friction of the bodies on the horizontal plane will ſeparate them from each other.

With reſpect to the inclined plane; let the line AB, *fig.* 64. repreſent the length of an inclined plane, AD its height, and the line BD we may call its baſe. Let the circular body GEF be ſuppoſed to reſt on the inclined plane, and to be kept from falling down it by a ſtring CS tied to its centre C. Then the force with which this body ſtretches the ſtring will be to its whole weight as the line of ABD, the angle of elevation, to the line of the angle which the ſtring contains with a line perpendicular to AB, the length of the plane. For let the radius CE be drawn perpendicular to the horizon, and CF perpendicular to AB, and from E draw EO parallel to the ſtring and meeting CF in O: then, as the body continues at reſt, and is urged by three forces, to wit, by its weight in the direction CE, by the reaction of the plane in the direction FC, and by the reaction of the ſtring in the direction EO; the reaction of the ſtring, or the force by which it is ſtretched, is to the weight of the body as EO to CE: that is, as the line of (the angle ECO, which is equal to) ABD, the angle of elevation, to the line of the angle EOC, equal to SCO, the angle which the ſtring contains with the line CF perpendicular to AB, the length of the plane.

When therefore the ſtring is parallel to the length of the plane, the force with which it is ſtretched, or with which the body tends down the inclined plane, is to its whole weight, as the line of the angle of elevation, to the radius, or as the height of the plane to the length. And in the ſame manner it may be ſhewn, that when the ſtring is parallel to BD, the baſe of the plane, the force with which it is ſtretched is to the weight of the body as AD to BD, that is, as the height of the plane to its baſe. If we ſuppoſe the ſtring, which ſupports the body GEF, to be faſtened at S, and that a force, by acting on the line AD, the height of the plane, in a direction parallel to the baſe BD, drives the inclined plane under the body, and by that means makes it riſe to a direction parallel to AD: then, from what was proved in the third caſe of the wedge, it will appear, that this force muſt be to the weight of the body, as AD to BD, or rather in a proportion ſomewhat greater; if it makes the plane move on and the body riſe.

From this laſt obſervation we may clearly ſhew the nature and force of the ſcrew; a machine of great efficacy in raiſing weights, or in preſſing bodies cloſely together.

For if the triangle ABD be turned round a cylinder whoſe periphery is equal to BD, then the length of the inclined plane BA will raiſe round the cylinder in a ſpiral manner, and form what is called the thread of the ſcrew, and we may ſuppoſe it continued in the ſame manner round the cylinder from one end to the other; and AD, the height of the inclined plane, will be every where the diſtance between two contiguous threads of this ſcrew, which is called a convex ſcrew. And a concave ſcrew may be formed to fit this exactly, if an inclined plane every way like the former be turned round the inſide of a hollow cylinder, whoſe periphery is ſomewhat larger than that of the other. Let us now ſuppoſe the concave ſcrew to be fixed, and the convex one to be fitted into it, and a weight to be laid on the top of the convex ſcrew; then, if a power be applied to the periphery of this convex ſcrew to turn it round, at every revolution the weight will be raiſed up through a ſpace equal to the diſtance between the two contiguous threads, that is to the line AD, the height of the inclined plane BA; therefore ſince this power, applied to the periphery, acts in a direction parallel to BD, it muſt be to the weight it raiſes as AD to BD, or as the diſtance between two contiguous threads, to the periphery of the convex ſcrew.

The diſtance between two contiguous threads is to be meaſured by a line parallel to the axis; if we now ſuppoſe that a hand-ſpike or handle is inſerted into the bottom of the convex ſcrew, and that the power which turns the ſcrew is applied to the extremity of this handle, which is generally the caſe; then as the power is removed farther from the axis of motion, its force will be ſo much increaſed, and therefore ſo much may the power itſelf be diminiſhed. So that the power, which, acting on the end of a handle, ſuſtains a weight by means of a ſcrew, will be to that weight, as the diſtance between two contiguous threads of the ſcrew to the periphery deſcribed by the end of the handle. In this caſe we may conſider the machine as compoſed of a ſcrew and a lever, or as Sir Iſaac Newton expreſſeth it, *Cuneus a vecte impellitur*. See Maclaurin's Account of Sir Iſaac Newton's Phil. Diſc. book ii. chap. 3. Hamilton's Phil. Eſſ. eſſ. 1. or Phil. Tranſ. liii. p. 116.

MECHANICAL is alſo applied to a kind of *reaſoning*, which of late has got great ground, both in phyſics and medicine; thus denominated, as being conformable to what is uſed in the contrivance, and accounting for the properties and operations of machines. See MEDICINE.

This manner of thinking and arguing, Dr. Quincy obſerves, is the reſult of rightly ſtudying the powers of an human mind, and the ways by which it is only fitted to get acquaintance with material beings: for conſidering an animal body as a compoſition out of the ſame matter from which all other bodies are formed, and to have all thoſe properties which concern a phyſician's regard, only by virtue of its peculiar make and conſtructure; it naturally leads a perſon to conſider the ſeveral parts, according to their figures, contexture, and uſe; either as wheels, pullies, wedges, levers, ſcrews, chords, canals, ciſterns, ſtrainers, or the like; and throughout the whole of ſuch enquiries, to keep the mind cloſe in view of the figures, magnitudes, and *mechanical* powers of every part or movement; juſt in the ſame manner, as is uſed in inquiring into the motions and properties of any other machine. For which purpoſe it is frequently found helpful to deſign, or picture out in diagrams, whatſoever is under conſideration, as it is cuſtomary in common geometrical demonſtrations.

The knowledge obtained by this procedure is called *mechanical knowledge*.

MECHANICAL is alſo uſed, in *Mathematics*, to ſignify a conſtruction or proof of ſome problem, not done in an accurate and geometrical manner, but coarſely and inartfully, or by the aſſiſtance of inſtruments; as are moſt problems relating to the duplicature of the cube, and the quadrature of the circle.

MECHANICAL *arts*. See ART.

MECHANICAL *curves*. See *Tranſcendental* CURVE.

MECHANISM *of the barometer*. See BAROMETER.

MECHANISM *of the double microſcope, &c.* See MICROSCOPE.

MECHOACAN, MECHOACANNA, called alſo *white jalap*, and *American ſcammony*, a medicine ſo taking its name from a province of Mexico, from which it is brought in thin tranſverſe ſlices, like JALAP, but larger and whiter. *Mechoacan* ſcarcely yields one fifth part ſo much reſin as jalap does. It is a ſpecies of bind-weed. See CONVOLVULUS.

Mechoacan was firſt introduced about the year 1571, and uſed as a purgative before jalap, though the latter is now in more general uſe, as being found more efficacious: but *mechoacan* is the milder and more gentle of the two,

on that account is preferable. The seat of its action is chiefly in the extreme parts; for which reason it is accounted good in arthritic pains. It has the advantage of needing no preparation, or corrective; and of purging in its own proper substance, as it grows.

It purges serous humours from all parts of the body; and helps the dropsy, jaundice, and rheumatism, working with gentleness, and without griping; and therefore it is fit for weakly tender constitutions; but by reason that a larger quantity must be given than most people are willing to take, it is grown very much out of use. The dose in substance is from one dram to two or more.

M. Boulduc found, by analysing it, that it contains twelve times as much salt as resin; but neither the saline nor resinous extract purge so freely as the substance, even though taken in larger doses; nor do they even purge so easily.

In the choice of *methonicum*, prefer those pieces which are the browneſt within, and whose substance is the closeſt, and most compact.

MECONIUM, Μηκώνιον, from μηκων, *poppy*, in *Pharmacy*, is the juice of the POPPY, drawn by incision, and dried.

Meconium differs from opium, in that this first oozes out spontaneously, after an incision made in the heads of the poppies, whereas the other is drawn by violence, both from the heads and leaves, and even from the whole plant, bruised and preſsed together.

The college of London directs the dried heads, cut and cleared from the seeds to be boiled in water, in the proportion of three pounds and a half to six gallons, and now and then stirred to prevent their burning, till only about one third part of the liquor remains, which will be almoſt entirely soaked up by the poppies: the decoction is to be strongly preſsed out, boiled down to about four pints, then strained whilſt hot, first through a sieve, and afterwards through a fine woollen cloth, and set by for a night to settle: to the liquor poured off clear six pounds of double refined sugar are to be added; and the mixture boiled till its weight comes to nine pounds or a little more, that it may become a syrup of a proper consistence.

An ounce of this syrup is reckoned equivalent to about a grain of opium. See DIACODIUM.

MECONIUM is also a black thick excrement, gathered in the intestines of a child during the time of gestation.

In colour and consistence it resembles pulp of cassia. It is also thought to resemble *meconium*, or juice of poppy; whence it takes its name. See INFANT.

MEDAL, MEDALIA, a small figure, or piece of metal, in form of a coin, destined to preserve to posterity the portrait of some great man, or the memory of some illustrious action.

Scaliger derives the word from the Arabic *methallia*, a coin whereon is impreſsed the figure of a human head. Menage and Vossius rather derive it from *metallum*. Du-Cange observes, that the obolus was anciently called *medalia quaſi medietas nummi*; as being half of another coin.

Medals may be distinguished by the metal of which they are made; which is commonly one of the three metals signified by the three A's, which, on several coins, are placed after the name of the mint-maſter, viz. gold, silver, and copper, or brass. There are also some *medals* compoſed of two different metals, not by melting them together, but either by plating over brass or iron with silver; a sort of false money, which had its rise in the triumvirate of Augustus; or by laying a rim of a different metal round the edge of a *medal*. Those of the latter sort are called by antiquaries *contorniate*, from the French *contour*, which signifies the outline that defines a figure. F. Hardouin allows these no higher antiquity than the thirteenth century; others date them from the fifth; and others make them as ancient as the time of Nero. *Medals* may again be distinguished by their different sizes. The size of the ancient *medals* is from three inches to one-fourth of an inch in diameter. Those of the larger size or volume are called MEDALLIONS. The others, which are very various, are ranked into three classes, viz. large, middle, and small; and the class is determined, not so much by the breadth and thickness of the *medal* itself, as by the size of the head that is stamped upon it. The shape of *medals* is rather roundish than perfectly round.

MEDAL, *the parts of a*, are the two sides; one whereof is called the *face*, or *head*, the other the *reverse*.

On each side is the area, or field, which makes the middle of a *medal*; the rim, or border; and the EXERGUM, which is beneath the ground whereon the figures represented are placed. On the two sides are distinguished the type, and the inscription or legend. The type or device, is the figure represented; the legend is the writing, especially that around the *medal*; though in the Greek *medals*, the inscription is frequently in the area. See LEGEND. What we find in the EXERGUM is frequently no more than some initial letters, whose meaning we are usually unacquainted with; though sometimes too they contain epochas, or words that may be accounted an inscription.

The exergue contains sometimes the date of the coin, expreſsing in what consulship of the emperor it was struck: as COS. III. upon the reverse of an Antoninus. Sometimes it signifies the place where it was struck, and to which the coin properly belonged, as S. M. AL. for *signa Moneta Alexandrina*, upon the reverse of a Licinius. Sometimes the name of a province, the reduction of which the *medal* is designed to celebrate; as Judæa in the reverse of a Vespasian. On the face of *medals* we have commonly the portrait of some great and illustrious person; usually, if not always, in profile. The consular *medals* have commonly the heads of some of their gods, or of their ancient kings, or of Rome, which is a manly face wearing a helmet. The heads of the Roman kings are generally dreſsed with a diadem; Julius Cæsar was the first among the Romans who struck his own head upon the coin, in which he was followed by all the succeeding emperors. The proper dreſs of the imperial head is a crown, commonly of laurel, the right of wearing which was decreed to Julius Cæsar by the senate, and afterwards continued to his succeſsors. Besides, there are several crowns found in *medals*, as the roſtral, mural, radiated, &c. The emperor Justinian was the first who used an arched crown, surmounted with a croſs; such as is wore by Christian kings at this day. Some heads of emperors are wholly naked, as those of Augustus, Nero, Galba, and some others. Though it is observed, that a naked head, struck in the imperial ages, is a sign that it is not the head of an emperor, but of one of his sons, or the presumptive heir of the empire. The heads of the gods are distinguished by their proper crown; as Ceres, by a crown of ears of corn; Flora, by a crown of flowers, &c. See CROWN. Heads are also distinguished, not only by their dreſs, but by certain symbols attending them; as the LITUUS, which is the symbol of the Pontifex Maximus. We have also on *medals* the heads of queens and other ladies of high rank; chiefly the wives of the emperors. Some *medals* are also charged with two heads, either set face to face, as the *medal* of Severus and the empreſs Donna, or back to back, as that of Julius Cæsar and Octavianus, afterwards Augustus, his adopted son and succeſsor: and some few are stamped with three heads or more on the face. The titles are also generally found upon the face of the *medal*. These are titles of honour, as Imperator, Cæsar, Augustus, given to all the Roman emperors after Octavianus; Dominus first assumed by Aurelian, and used by his succeſsors: other titles are ascribed to particular persons on account of their virtues, as Pius to Antoninus, assumed also by Commodus with the addition of Felix; Pater Patriæ, first bestowed on Cicero for discovering and defeating the conspiracy of Cataline, and afterwards assumed by the emperors; Justus, the title of Pisceninus; Beatissimus and Felicissimus, of Diocletian; Optimus and Clemens, decreed to Trajan by the senate; Maximus, assumed by Constantine; and Invictus, by Victorinus. Other titles are the names of offices; as cos. for consul, with a number annexed to it, signifying how many times the person had been thus elected: Tribunitia potestas, with the year of the tribuneship commonly expreſsed after the title, as TRIB. POT. X. or XVI. &c. The office of Pontifex maximus, expreſsed by P. M. was assumed by the emperors, and generally expreſsed among their titles from Augustus to Constantine, by whom it was refused; it was reassumed by Julian, and laid aside by Gratian. Julius Cæsar assumed the title of Dictator perpetuus; Claudius, that of Censor; and Domitian made himself Censor perpetuus.

Some authors imagine, that the ancient *medals* were used for money. M. Patin has a chapter expreſs to prove, that they had all a fixed regular price in payments, not excepting even the medallions. P. Joubert is of the same opinion. Others, on the contrary, maintain, that we have no real money of the ancients; and that the *medals* we now have, never had any course as coins. Between these two extremes there is a medium, which appears by much more reasonable than either of them. See MONEY.

MEDALS are divided into *ancient* and *modern*.

MEDALS *ancient*, are either of the higher or lower antiquity. The former class consists of such as were struck before the end of the third century: the latter, of such as were struck between the third and ninth centuries.

The *aruga* of ancient *medals* adds greatly to their value. It is sometimes found of a blue, sometimes of a crimson, and sometimes of a violet colour. It is said to be inimit-

able by art; for as to that produced by sal ammoniac and vinegar, it comes far behind it in beauty. The genuine kind insinuates itself into the finest strokes of the letters, &c. without effacing them, better than any enamel; it is only observed on brass coins: for as to those of silver, the *aruga* destroys them, and therefore is to be carefully scoured off with vinegar, or lemon juice. Joubert. Scient. des Medail. sect. 8. Act. Erud. Lipf. 1693. p. 226.

MEDALS, *modern*, are those struck within these few hundred years. See COIN.

Among the ancient *medals*, some are Greek, others Roman. These may be distinguished into two classes, viz. those of the state, and those of particular cities and colonies: for besides the money coined by the state, it appears that divers cities and colonies had the privilege of coining; where it is probable the chief magistrate was the mint-master. Hardouin has published a large catalogue of Grecian and Roman *medals*, of this sort, in a quarto volume, intitled, *Nummi antiqui Populorum et Urbium illustrati*. Vaillant has explained the devices and inscriptions of *medals*, in two volumes of the Latin colonies, in which he has also given cuts of the *medals* themselves. The *medals* belonging to cities were so numerous, that above two hundred may still be collected of the Greek cities only. The Greek *medals* are the most ancient. That people struck *medals* in all the three metals, with such exquisite art as the Romans could never come up to. The Greek *medals* have a design, accuracy, force, and a delicacy that expresses even the muscles and veins; and it must be owned goes infinitely beyond any thing of the Romans.

There are also Hebrew *medals*; and Punic, Gothic, and Arabic *medals*, which make new classes in the ancient and modern ones.

MEDALS, *consular*, are so called to distinguish them from the imperial; not that they were struck by order of the consuls, but because, in those times, the republic was governed by consuls. Of these, father Joubert reckons about fifty or sixty of gold; two hundred and fifty of copper; and near a thousand of silver. Goltzius has described them in a chronological order, according to the Fasti consulares; and Urſinus has disposed them genealogically, according to the order of the Roman families. M. Patin has collected an entire series of them, in the same order with Urſinus; and only computes one thousand thirty-seven consulars, which relate to one hundred seventy-eight Roman families. M. Vaillant, and M. Morel, each promised a new edition of the consular *medals*. M. Vaillant kept his word, and his book was printed before he died, in three volumes folio.

The consular *medals* are certainly the most ancient *medals* of the Romans, and yet those of copper and silver do not go beyond the four hundred eighty-fourth year of Rome; nor those of gold beyond the five hundred forty-sixth. If any are produced of an elder date, they are condemned as spurious.

MEDALS, *among the Imperial*, we distinguish between the *upper* and the *lower empire*: the upper empire commenced under Julius Cæsar, and ended about the year of Jesus Christ two hundred and sixty: the lower empire comprehends near one thousand two hundred years; viz. till the taking of Constantinople. It is the custom, however, to account all the imperial *medals*, till the time of the Paleologi, among the antique; and yet we have no imperial *medals*, of any considerable beauty, later than the time of Heraclius; who died in 641.

After the time of Phocas and Heraclius, Italy became a prey to the barbarians; so that the monuments we have remaining of those two emperors, finish the set, or series of imperial *medals*. To these are added the *medals* of the lower empire, and of the Greek emperors; whereof a series may be made as low as our times, taking in the modern ones. M. Patin has made an ample collection of the imperial *medals*, till the time of Heraclius.

The Gothic *medals* make part of the imperial ones: they are so called, as having been struck in the times of the Goths, and in the declension of the empire, and favouring of the ignorance and barbarity of the age.

As to modern *medals*, they are such as have been struck in Europe, since the usurpation of the Goths has been extinct, and sculpture and engraving have begun to re-flourish. The first was that of the famous reformer John Huſs, in 1415. If any pretend to be more ancient, they are spurious. In France, there were none struck with the king's effigy, before the reign of Charles VII.

The study of modern *medals* is so much the more useful, as they afford more light than the ancient, and mark the times and consequences of events more precisely; whereas the inscriptions of the ancient *medals* are very short and simple, and generally they are without any date. Add to this, that the ancient *medals* are extremely liable to be counterfeited, by reason of the considerable price they bear; but in the modern there is not that danger of being imposed upon.

There are few true Hebrew *medals*: those which we see of the heads of Moſes, and Jesus Christ, are spurious and modern. We have a few shekels of copper and silver with Hebrew or Samaritan legends, but none of gold; though there is mention made of one in the king of Denmark's cabinet. F. Souciet has a diſsertation on the Hebrew *medals*, commonly called *Samaritan medals*, where he diſtinguiſhes accurately between the genuine and the spurious; and shews, that they are true Hebrew coins, struck by the Jews, but on the model of the ancients; and that they were current before the Babyloniſh captivity.

MEDALS, *ſingular*, in the popular senſe, are such as are not found in the cabinets of the curious, and are only met with by chance; but in the ſtricter senſe, they are such whereof there is not above one of the kind extant. The Otho, in large copper, is a *ſingular medal*. When a *medal* exceeds the value of ten or twelve piſtoles, it is worth what the owner pleaſes. The Pescennius Niger, and Pertinax, are very rare in all metals. The Didius Juſianus is hardly found any where but in large copper. Carneros, a Dutchman, and some others, have made mills on purpoſe to ſtrike *medals* that never were; as those of Cicero, Virgil, Priam, &c.

MEDALS, *Greek*, are such as have either the heads of Greek emperors, or Greek inscriptions.

MEDALS, *falſe* or *ſpurious*, are those counterfeited, and put off for antique, when they are not.

MEDALS, *mutilated*, are those that are not entire, or are much defaced.

MEDALS, *reſtituti*, are those wherein we find the letters RESTIT. which ſhew that they have been reſtored by the emperors.

MEDALS, *dipt*, are ſtruck of pure copper, and afterwards silvered. This is a contrivance that the curious have frequent recourſe to, in order to complete their silver ſets.

MEDALS, *covered* or *plated*, are those which have only a thin ſilver leaf over the copper, but which are ſtruck ſo artfully, that the cheat does not appear without cutting them; these are the leaſt ſuſpected.

MEDALS, *grained* or *indented*, are those whoſe edges are cut, or notched, like teeth, which is a ſign of purity and antiquity. They are common among the consulars, but we have none later than Auguſtus. There are ſeveral of them, however, among those of the kings of Syria.

MEDALS, *counter-marked*, are those which have marks cut either on the ſide of the head, or of the reverſe. These countermarks ſerve to denote the change of their value; and this kind is much inquired for by the curious.

MEDALS, *caſt*, are those which are not ſtruck, but caſt in a mould.

MEDALS *without reverſe*. See REVERSE.

Medals have been ſtruck in three kinds of metals, which make three ſeveral ſets or series, in the cabinets of the curious. That of gold is the leaſt numerous, as not conſiſting of above one thouſand, or twelve hundred of the imperial; that of ſilver may contain about three thouſand imperial; and that of *brass* or copper, of the three ſeveral ſizes, viz. the great, the middle, or the ſmall, conſiſts of ſix or ſeven thouſand, all imperial.

It is not either the metal, or the ſize, which makes a *medal* valuable; but the ſcarcity of the head, or of the reverſe, or the legend. Some *medals* are common in gold, which yet are very rare in copper; and others very rare in ſilver, which in copper and gold are very common. The reverſe is ſometimes common, where the head is ſingular; and ſomeheads are common, whoſe reverſes are very ſcarce.

There are alſo *medals* very ſcarce in ſome ſets, and yet very common in others: for inſtance, there is no Annia in the ſets of large copper, and the middle copper is forced to ſupply its place. The Otho is very rare in all the copper ſets, and yet common in the ſilver ones. Othus, of the large copper, are held at an immenſe price; and thoſe of the middle copper at forty or fifty piſtoles. And the Gordians Afric are rated near as high. Singular *medals* are invaluable.

M. Vaillant has collected all the *medals* ſtruck by the Roman colonies; F. Hardouin thoſe of the Greek and Latin cities; F. Noris thoſe of Syria. M. Morel alſo undertook an univeral hiſtory of *medals*, and promiſed each of twenty-five thouſand. He ranges them under four claſſes; the firſt contains the *medals* of kings, cities, and people, which have neither the name nor image of the Roman emperors; the ſecond contains the conſular *medals*; the third the imperial *medals*; and the fourth, the Hebrew, Punic, Parthian, French, Spaniſh, Gothic, and Arabic. He begins with the imperial, and brings

them

them down as low as Heraclius: he places the Latin in order before the Greek.

Ad. Occo, a German phyſician, and count Mezzabarba, have endeavoured to range the *medals* in a chronological order; but that is impracticable: for in many of the imperial *medals* there is no mark, either of the conſulate, or of the year of the reign; and ſince Gallienus there are few of the Roman imperial *medals* that bear the leaſt footſteps of chronology.

The moſt noted *medalliſts*, or authors on *medals*, are Antonius Auguſtinus, Wolf. Lazius, Ful. Urſinus, a learned antiquary, Æneas Vicus, Hubert Goltzius, a famous graver, Orſelius, Seguin, Occo, Triſtan, Sirmond, Vaillant, Patin, Noris, Spanheim, Harduin, Morel, Joubert, Mezzabarba, Beger, &c.

There is an introduction to the Knowledge of *Medals*, by Dr. Jennings, publiſhed in 1764, which may be uſeful to convey a general acquaintance with the ſubject.

For the manner of ſtriking *medals*, ſee COINING.

MEDALS, *academy of*. See ACADEMY.

MEDAL, *repairing a*. See REPAIR.

MEDALS, *reſtitution of*. See RESTITUTION.

MEDALS, *votive*. See VOTIVE.

MEDALS, *impreſſion of*. A very eaſy and elegant way of taking impreſſions of *medals* and coins, not generally known, is this: melt a little iſinglaſs glue, made with brandy, and pour it thinly over the *medal*, ſo as to cover its whole ſurface; let it remain on for a day or two, till it is thoroughly dry and hardened, and then taking it off, it will be fine, clear, and hard as a piece of Muſcovy glaſs, and will have a very elegant impreſſion of the coin. Shaw's Lectures, p. 430.

Sulphur is ſometimes uſed to take off impreſſions of *medals*, coins, &c. The method is this: having made a ledge of clay about the work, whoſe impreſſion is deſired, and carefully oiled the whole, gently pour brimſtone melted in a covered veſſel, to prevent its firing, upon the metal. About the edge of this mould make a border of clay, as before, and lightly oil the internal ſurface of both; then gradually put into it, to the thickneſs of about a quarter of an inch, a mixture made up with calcined alabaſter and water, to the conſiſtence of ſtiff honey. This ſoon growing hard, may be taken out of the mould, and gives figures of the coin or *medal*.—Boyle's Works abr. vol. I. p. 151. A method ſomewhat different is deſcribed in the article BRIMSTONE.

The brittleneſs of ſulphur is a great objection to this method, and the plaiſter of Paris, which is often uſed for taking impreſſions, is too ſoft: however a coat or layer of thin metal, formed over the plaiſter, would be a conſiderable defence. This is the cheapeſt and moſt convenient metal for this purpoſe: let thin tin-foil, ſuch as is uſed for ſilvering looking-glaſſes, be laid over the *medal* or coin intended to be taken off, and then rubbed either with a brush, the point of a ſkewer or a pin, till it has received perfectly the impreſſion of the *medal*; then pare off the tin-foil round the edge of the *medal*, till it is brought to the ſame circumference; afterwards the *medal* muſt be reverſed, and the tin-foil will drop off into a chip-box or mould ready to receive it; the concave ſide of the foil, or that which is laid on the face of the *medal*, being uppermoſt; upon this pour plaiſter of Paris, made in the uſual manner, and when dry, the caſt figure may be taken out of the box or mold, with the tin-foil ſticking on the plaiſter, the convex ſide being now uppermoſt, in which poſition it is to be kept in the cabinet after it becomes dry. To have an impreſſion very perfect, the thinneſt tin-foil ſhould be made uſe of. The impreſſions taken in this manner almoſt equal ſilver *medals* in beauty, and are very durable. If the box or mould be rather larger than the impreſſion of tin-foil, the plaiſter, when poured on, runs round it edges, and forms a kind of white frame or circular border round the foil, whence the new made *medal* appears more neat and beautiful. If this tin-foil is gilt with gold-leaf, by means of thin iſinglaſs glue, the *medal* will reſemble gold.

We have an eaſy method of procuring the true impreſſion or figure of *medals* and coins, by Mr. Baker in the Philoſ. Tranſ. N° 472. ſect. 13. vol. xliii. p. 77.

Take a perfect and ſharp impreſſion in the fineſt black ſealing-wax, of the coin or *medal* you deſire. Cut away the wax round the edges of the impreſſion; then with a preparation of gum-water, of the colour you would have the picture, ſpread the paint upon the wax-impreſſion with a ſmall hair-pencil, obſerving to work it into all the ſinking or hollow places, theſe being the riſing parts of the *medal*; and the colouring muſt be carefully taken from the other parts with a wet finger. Then take a piece of very thin poſt-paper, a little larger than the *medal*, and moiſten it quite through. Place it on the wax-impreſſion, and on the back of the paper lay three or four pieces of thick woollen cloth or flannel, or about the ſame ſize. The impreſſion, with its coverings, ſhould be placed between two ſmooth iron-plates, about two inches ſquare, and one tenth of an inch thick. Theſe muſt be carefully put into a ſmall preſs, made of two plates of iron, about five inches and a half long, one inch and a half wide, and half an inch in thickneſs, having a couple of long male ſcrews running through them, with a turning female ſcrew on each, to force the plates together. Theſe being brought evenly together, by means of the ſcrews, will take off a true and fair picture of the *medal*; which, if any deficiencies ſhould appear, may eaſily be repaired with a fine pencil or pen, dipped in the colour made uſe of.

If a relievo only be deſired, nothing is neceſſary but to take a piece of card, or white paſte-board, well ſoaked in water, then placing it on the wax-mould, without any colouring, and let it remain in the preſs for a few minutes, a good figure will be obtained.

This method of taking off *medals*, &c. is convenient, and ſeems much more to than the ſeveral inventions uſually practiſed in ſulphur, plaiſter of *Paris*, paper, &c. wherein a mould muſt be formed, either of clay, horn, plaiſter, or other materials, which require time and trouble.

Some take impreſſions on paper from the *medals* themſelves, by paſſing them through the rolling-preſs, and colouring them afterwards; but this is not only more difficult, but does great injury to the *medals*, by impairing the ſharpneſs of their moſt delicate and expreſſive ſtrokes: whereas wax does not hurt the fineſt *medal* in the leaſt degree; and though a brittle ſubſtance, yet it effectually reſiſts the force of a downright preſſure.

Red ſeems the beſt colouring, and therefore black wax directed to be uſed; but if the pictures are to be in black and white, to reſemble copper-plates, the wax ſhould be red; for the wax and paint ought to be of different colours, in order to diſtinguiſh when the colour is laid on properly, or rightly cleared away.

The ſubſtance of *medals*, being metalline, is liable to be corroded; and the figures being raiſed, are alſo liable to be effaced by friction. Hence it is rare to find any perfectly preſerved. Gems are not ſubject to theſe inconveniences. See GEM.

MEDALLION, or MEDALION, *a medal* of extraordinary bigneſs.

The word is formed from the French *Medaillon*, or Italian *Medaglione*, which ſignify the ſame; and which were originally formed from *Metalliones*, a name by which theſe pieces are frequently called in ancient Latin writers.

Medallions are ordinarily a kind of *medals*, which princes uſe to preſent, as a token of honour or eſteem; for which reaſon the Romans call them *miſſilia*.

Medallions were never any current coins, as medals probably were: they were ſtruck purely to ſerve as public monuments, or to make preſents of.

There cannot be any ſet made of them, even though the metals and ſizes ſhould be joined promiſcuouſly. The beſt cabinets do not contain above four or five hundred, though M. Morel judges them to be above a thouſand.

Authors vary about the time when they firſt began to be ſtruck. Some antiquaries will have it under the empire of Theodoſius, but this muſt be a miſtake; for there were ſome ſtruck even in the upper empire: witneſs a Nero, a Trajan, and an Alexander Severus, ſtill extant. *Medallions* of gold are very rare, as alſo thoſe of a large copper.

Medallions are diſtinguiſhed from medals by the volume, that is, by the thickneſs and compaſs, as well as by the largeneſs and relievo of the head.

MEDALLION, in *Architecture*, is any circular tablet on which are imboſſed figures or buſtos: ſuch is L. introduced in the tympanum of the pediment, *Tab. Architecture, fig.* 40.

MEDEA, the name of a ſtone deſcribed by Pliny and the ancients. They ſay it was black, and was variegated with gold-coloured veins; and that when rubbed in water, it yielded a yelloviſh red juice, which had the flavour of wine. We know no ſtone at preſent anſwering theſe characters. Rulandus, indeed, mentions a kind of black hæmatites, or blood-ſtone, which tinges water to a faffron colour. This account he takes from Encelius; but this wants the much greater character, of giving it the taſte of wine.

MEDENA, a word uſed by Paracelſus to expreſs an inveterate kind of ulcer.

MEDEOLA, *climbing aſparagus*, in *Botany*, a genus of the *decandria trigynia* claſs. Its characters are theſe: the flower has no empalement; it has ſix oblong oval petals, and ſix awl-ſhaped ſtamina terminated by incumbent ſummits; and three horned germina terminating the ſtyle; the germina afterward turn to a roundiſh trifid

trifid berry, with three cells, each containing one heart-shaped seed. Miller reckons four, and Linnæus only two.

MEDES, *empire of the.* See EMPIRE.

MEDIALE, in *Botany*, a name given by the ancients to the central part of any tree. It is sometimes used to signify the spungy pith that fills up the young branches of a tree, as in the elder and the like; and sometimes for the firm and hard substance, called the heart of the wood, and found to be much harder than any other part of it. Thus the name of *tree*, to which the word *mediale* is annexed, must be the means of explaining what is meant by the word, whether a spongy pith, or a sound hard wood. The most accurate writers, however, make a distinction which ought to be kept up, that is, the calling the heart, or sound internal part of the wood, only *mediale*, and the spungy part within the elder &c. *medulla.*

MEDIANA, the name of a vein, or little vessel, made by the union of the cephalic and basilic, in the bend of the elbow. It is not a particular vein, or a third vein of the arm, as some authors imagine, but merely a branch of the basilica; which running into the inner part of the elbow, unites with the cephalica, and forms a common vein, called *mediana*, and by the Arabs, the *black vein.* See *Tab. Anat. (Angeiol.) fig.* 6. *lit. p.*

MEDIANA *linea*, a line, or seam, running down the middle of the tongue, and dividing it into two equal parts; though not so effectually, but that the blood-vessels of the one side communicate with those of the other. See TONGUE.

MEDIANÆ, *columnæ*, in Vitruvius, are the columns in the middle of a portico, whose intercolumnation is to be larger than those of the angular columns.

MEDIANTE, in *Music. The mediant of a mode* is that note which is a third higher than the final; or that which divides the fifth of every authentic mode into two thirds. See MODE and THIRD.

This term is chiefly in use among the French.

MEDIASTINA, the name of a vein of the mediastinum.

MEDIASTINUM, in *Anatomy*, a double membrane, formed by a duplicature of the pleura; serving to divide the thorax and the lungs into two parts, and to sustain the viscera, and prevent their falling from one side of the thorax to the other. See THORAX.

It proceeds from the sternum, and passing strait down through the middle of the thorax to the vertebræ, divides its cavity into two. It contains the heart between its two laminæ, and it affords a passage to the vena cava, the œsophagus, and the stomachic nerves. The membranes of the *mediastinum* are finer and thinner than the pleura, and have a little fat. It receives branches of veins and nerves from the mamillary and diaphragmatic, particularly one called *mediastina*; its nerves come from the stomachic; it has also some lymphatics, which open in the thoracic duct.

The *mediastinum* divides the thorax longitudinally into two parts; and, by means of it, one lobe of the lungs may officiate, if the other be hindered by a wound on the other side. Sometimes there is a matter contained betwixt its membranes, immediately under the sternum, which may occasion the tapping of this place.

This membrane is subject to an inflammation, the pain of which strikes obliquely from the sternum through the breast to the back, attended with a difficulty of breathing, cough, and sometimes spitting. The cause, symptoms and cure are much the same with those of the PLEURISY; but suppuration, which is with difficulty avoided, is always fatal.

MEDIASTINUM *cerebri*, the same with SEPTUM *transversum.*

MEDIATE, or INTERMEDIATE, a term of relation to two extremes, applied to a third, which is in the middle between them. See MEAN, and MEDIUM.

Substance is a genus with regard to man; but between the two there are other *mediate* genusses, as body and animal.

Mediate stands opposed to *immediate*: thus when we say, that God and man concur to the production of man; God is the *mediate* cause, man the *immediate.*

MEDIATE *pulse.* See MODE.

MEDIATORS *of questions*, in our old writers, were six persons authorized by statute, who, upon any question arising among merchants, relating to any unmerchable wool, or undue packing, &c. might, before the mayor, or officers of the staple, upon their oath, certify and settle the same; to whose order and determination therein, the parties concerned were to give entire credence, and submit. 27 Edw. III. stat. 2. c. 24.

MEDIATORS, Μεσαζοντες, under the emperors of Constantinople, officers of state, who had the direction of all affairs transacted at court. Their chief, or president, was called *magnus mesazon*, μεγας μεσαζων, and answered to the prime or grand visier of the Turks. Hofm. Lex. in voc.

MEDIC VETCHING. See SAINTFOIN.

MEDICA, in *Botany.* See LUCERNE.

MEDICA, *bastard.* See *Snail* TREFOIL.

MEDICA, *mairi*, in *Botany*, a name given by some authors to the citron-tree.

MEDICAL *stones.* See STONE.

MEDICAGO, in *Botany.* See *Snail* TREFOIL.

MEDICAMENTOSUS *lapis.* See LAPIS.

MEDICINAL *hours* are those parts of the day supposed most proper to take medicines in.

Of which there are usually reckoned four; viz. in the morning fasting, about an hour before dinner, about four hours after dinner, and going to bed; but in acute cases, the times are to be governed by the symptoms and aggravation of the distemper, without regard to any medicinal hours.

MEDICINAL *waters.* See WATER.

MEDICINALIS *succulus.* See SACCULUS.

MEDICINE, MEDICINA, the art of healing.

Medicine popularly called *physic*, consists, according to Boerhaave, in the knowledge of those things by whose application life is either preserved sound and healthy, or when disordered is again restored to its pristine healthiness.

Galen defines *medicine* the art of preserving present health, and of retrieving it when lost: Hippocrates, the addition of what is wanting, and the retrenchment of what is redundant: and Herophilus, the knowledge of things good, indifferent, and ill, with regard to health.

Medicine must have been nearly coeval with the world. The injuries and vicissitudes of the air, the nature and qualities of foods, the violence of external bodies, the actions of life, and, lastly, the fabric of the human compages, must have rendered diseases almost as old as mankind; and the presence of a disease, as it brings with it a painful sensation, or the loss, perhaps, of the use of a limb, does, by a necessary mechanical impulse, both in brutes and men, compel the diseased to seek for help, and to apply remedies, either by mere experiment, or by instinct, and spontaneous appetite: hence arose the art of *medicine*, which, in this sense, has been always, everywhere among mankind.

Ancient histories and fables tell us, that, in a little time from the flood, *medicine* was so well cultivated by the Assyrians, Babylonians, Chaldæans, and magi, that they were able to remove present diseases, and prevent future ones. Hence it passed into Egypt, Libya Cyrenaica, and Crotona; and thence into Greece, where it flourished, principally in the islands of Cnidus, Rhodes, and Cos, and in Epidaurus.

The first foundations of the art were laid by chance, natural instinct, and events unforeseen; these were improved by the memory of the success of former experiments; by writing down diseases, their remedies, and events, on columns, paintings, and the walls of their temples; by exposing the sick in the markets, and public ways, that those who passed by might inquire into the disease, and communicate a remedy, if they knew any; and, lastly, by analogy, or reasoning, from a comparison of things already observed, with things present, and things to come.

The art at length received a much greater degree of perfection, by the appointing of physicians; some for the cure of particular diseases, and others for diseases in general; by an accurate observation of the disease, and its symptoms; and by an exact description of the remedy, and its use: immediately upon which, it got among the priests, and at length was confined to particular families; descending by way of inheritance, from father to son: which again proved a great bar to its progress. The extispicy, or inspecting the entrails of beasts, used by the priests; the custom of embalming dead carcases; and even butchery itself, promoted the knowledge of the human fabric, and of the causes both of health, diseases, and death.

Lastly, the dissecting of live animals for philosophical purposes, distinct narratives of the cause, rise, increase, crisis, declension, end, and effect of diseases; and the application, powers, and events, seemed to have almost brought the art to its perfection.

Hippocrates, who was contemporary with Democritus, and perfectly acquainted with every thing then discovered, and besides furnished with a great number of observations of his own, collecting into one all that was valuable and useful, compiled a body of Greek *medicine*; and was the first who deserves the title of a true *physician*, for being a master of the *theories*, experience, as well as of analogy and reason, and with all well versed in pure philosophy, he first made physic rational; and laid the foundation

foundation of the dogmatical *medicine*, which has ever since obtained. See HIPPOCRATISM.

What Hippocrates had done continued a long time sacred and unaltered, and was the standing practice of many ages; at length Aretæus the Cappadocian digested it into a more orderly body; whence, in various places, at various times, and by various hands, particularly the Alexandrian school, it was farther altered and improved, till at length it came into the hands of Claud. Galen, who, collecting the scattered parts, digesting those which were confused, and explaining every thing by the rigid doctrines of the Peripatetics, did both a great deal of service and a great deal of injury to the noble art; he being the first who introduced the doctrine of the elements, the cardinal qualities, and their degrees, the four humours, &c. into *medicine*; and on these he made the whole art to depend.

After the sixth century, the arts were not only extinguished, but almost all memory of them was lost, till the ninth; from which to the thirteenth, *medicine* was vigorously cultivated by the Arabs in Asia, Africa, and Spain; who applying themselves particularly to the study of the materia medica, and its preparations, and to the operations of surgery, rendered both more just and more copious at the same time; and yet Galen's errors became now more predominant than ever.

At length, however, they were purged out and exploded by two different means; principally indeed by the restoration of the pure discipline of Hippocrates, in France; and then also by the experiments and discoveries of chemists and anatomists; till at length the immortal Harvey, overturning, by his demonstrations, the whole theory of the ancients, laid a new and certain basis of the science. Since his time, *medicine* is become free from the tyranny of any sect; and is improved by sure discoveries in anatomy, chemistry, physics, botany, mechanics, &c.

Hence it appears that the art originally consisted solely in the faithful collecting of observations; and that, a long time after, they began to inquire, and dispute, and form theories: the first part has ever continued the same; but the latter has been always mutable.

For the several sects that have arisen in *medicine*, see DOGMATIC, CHYMISTRY, EMPIRIC, GALENIST, HERMETICAL, and *Paracelsists*, or FIRE-*philosophers*.

Medicine is divided into five principal branches. The first considers the human body, its parts and fabric, life and health, and the effects following from them: this is called *physiology*, the *doctrine of the animal œconomy*, or *of the use of the parts*: and its objects, now enumerated, are called *res naturales*, or things according to nature.

The second branch considers the diseases of the human body, their differences, causes, and effects; and is called *pathology*, as it considers the diseases; *æziology*, as it inquires into their causes; *nosology*, when it examines their differences; and, lastly, *symptomatology*, when it explains their effects. The objects of this part are called *res præternaturales*, or beyond nature. For the modern method of classing diseases, see NOSOLOGY.

The third branch considers the signs or symptoms, and how to apply them to use; so as to judge, both in a sound and a diseased body, what will be the degree, order, and effect, of the health or the disease: this is called *semeiotica*: its objects are things both natural, non-natural, and preternatural.

The fourth branch considers the remedies, and their use, whereby life may be preserved; whence it is called *hygeine*: its objects are what we strictly call *non-naturals*. Lastly, the fifth furnishes the materia medica, its preparation, and manner of exhibition, so as to restore health, and remove diseases: and is called *therapeutica*, comprehending the *dietetica*, *pharmaceutica*, *chirurgica*, and *iatrica*.

MEDICINE, *clinical*, *medicina clinica*. See CLINICA.

MEDICINE, *characters in*. See CHARACTERS.

MEDICINE, *pandects in*. See PANDECT.

MEDICINES, or MEDICAMENTS, denote any natural substance, applied to a human body, in order to answer some intention of cure. So that they differ from aliments, which preserve the body in a sound state, whereas *medicines* restore it when impaired; and from poisons, which tend to destroy the body. All the parts of diet may indeed be termed alimentary *medicines*, inasmuch as they may serve to confirm health, against the first approaches of a disease; as poisons, which are always detrimental to the body, have been called deleterious *medicines*.

Medicines are either simple, or compound: simple *medicines* are those which are formed spontaneously, or by the assistance of nature alone; and those are called compound, which are owing to the art and industry of men, and to the mixtures of various simples put together.

The principal differences of simple *medicines* are taken either from their form and texture, or from their virtues. In respect of their texture, they are divided into minerals, vegetables, and animals; each of which divisions is termed a class, kingdom, or family.

In what the ancients have left us concerning the *medicines* they used, there is the utmost confusion and obscurity; the same substance is frequently called by many different names; some *medicines* are barely mentioned by them, without any account of their nature or description; and in regard to many others, the virtues ascribed by them to one simple, have been, by later writers, attributed to others. To clear up, and set right all those difficulties, at this time, would be a task as difficult as it would be useful. So great and so many virtues are ascribed, by different authors, to particular *medicines*, that, if they could be depended on, each ought to be looked on as an almost universal remedy: but as many of these virtues are merely imaginary, it requires even the greatest caution to distinguish the fictitious from those which truly belong to them; and though the knowledge of the virtues of *medicines* be at this time carried to a very great length, there are nevertheless many things remaining yet to be discovered, and room enough still to enrich the science with new specific remedies; nor will the judicious physician find less worthy employment for his thoughts, in endeavouring to determine the manner in which those *medicines* act, whose effects are already known, and to ascertain the safest and best methods of administering them.

Such *medicines* as are of a terrestrial, or other the like nature, and will not dissolve in water, the new Dispensatory of the college has ordered to be prepared in the following manner: they are first to be pounded in a mortar and then levigated with a little water, upon a hard and smooth marble, into an impalpable powder, and afterwards dried upon a chalk-stone, and then set by for a few days, in a warm, or at least a very dry place. In this manner are to be prepared amber, antimony, bezoar, which should be levigated with spirit of wine instead of water, blood-stone, calamy, first calcined for the use of the makers of brass, chalk, coral, crabs claws, crabs eyes (so called), egg-shells cleansed from the membrane adhering to them by boiling in water, oyster-shells first cleansed, pearls, verdegris, tutty.

In antimony, calamy, and tutty, singular care ought to be taken to reduce them to the most subtile powder that can be. Pemberton's College Disp. p. 145.

Medicines are again distinguished, with regard to the manner of their application, into *internal* and *external*.

MEDICINES, *internal*, are those taken in at the mouth.

MEDICINES, *external* or *topical*, are those applied outwardly to any particular part.

With regard to the different manner of their operation, *medicines* are distinguished into *agglutinant*, *alexant*, *stomachics*, *astringents*, *evacuants*, *incarnatives*, *specifics*, &c.

MEDICINES *from metals*. See METALS.

MEDICINES, *pocket*, in *Surgery*, are such necessary remedies as the surgeon ought never to be without, but always to carry in a convenient case or box about him. These are the common digestive ointment, and the brown or Egyptian ointment, for cleansing and digesting foul ulcers; and some vulnerary balsams, as the *linimentum Arcæi*, or the balsam of Peru, of Gilead, or Capivi, or the Samaritan balsam: to these must also be added a plaster or two, as the diachylon, or stypticum Crollii; since one or other of these is almost constantly wanted. Neither should there be wanting a piece of blue vitriol for the taking down luxuriant flesh, and to stop hæmorrhages; but if vitriol is wanting, burnt alum, red precipitate, the infernal stone, or any other corrosive *medicine*, will supply its place in corrosive intentions, and the last will also serve to open abscesses, to make issues, and perform many other operations of that kind. With these there should always be kept in readiness also a quantity of scraped lint, that the surgeon may be able to give immediate assistance to wounded persons, since, if he is unprepared for this, they may be easily taken off by an hæmorrhage, a circumstance which ought also to prevail with the surgeon never to be wholly unprovided with bandages. Heister's Surg. p. 11.

MEDICINES, *mechanical operation of*. To account for the operations of *medicines* mechanically, seems to have been the favourite scheme of physicians and physiologers of the last and present century. Stahl, and his disciples, reject these accounts, and think them sufficiently refuted by the operation of opium, and of astringents. One grain of opium, properly taken, will for a time assuage pains all over the body. A very few grains of crocus martis astringens sometimes stop an hæmoptysis, before they can be supposed to have entered into the humours

of the body. Is it not past all belief, say they, that so few grains, mixed with so many pounds of fluids, should retain any mechanical force, especially as it is well known that aſtringents loſe their force by dilution? They farther urge, that the various effects of the ſame *medicine* are a refutation of the mechanical hypotheſis; thus emetics ſometimes purge, and *vice verſâ*; aſtringents increaſe hæmorrhages; opium excites alacrity in ſome, inſtead of ſtupefying. Again, the ſight, or even bare imagination of ſome *medicines*, will produce a ſenſible effect on the body, without any contact. Stahl, and his followers, therefore, hold, that *medicines* operate chiefly by exciting the vital ſoule; and that this is the chief effect of *medicines*, even where they ſeem moſt to act mechanically.

Hoffman, Heiſter, and others, have attacked the hypotheſis of Stahl. We ſhall not pretend to give any farther account of the controverſy; perhaps in this, as in others, there may be a good deal of logomachy; ſtrictly ſpeaking, mechanical principles muſt be ſufficient to account for the operation of *medicines*, as this ſometimes undoubtedly depends (in the *prima via* at leaſt) on chemical principles; and nobody has hitherto been able to account mechanically for the phenomena of chemiſtry. The laws of the *minima naturæ* have not hitherto been reduced to thoſe of the preſſure and impulſe of large ſenſible maſſes. And perhaps when the laws, that obtain in the minute parts of matter, have been found, we ſhall ſtill be at a loſs to account for all the phenomena of animated bodies, particularly the human.

Heiſter ſays, Stahl pretends that the rational ſoul and nature are ſynonymous terms; and that it is the rational ſoul which formed the fœtus in the womb, and which [illegible] animal, and natural actions, to the pre[illegible] body; hence ſometimes exciting evacu[illegible] times ſpaſms, to get rid of diſorders.—[illegible]r. de Medecin. Mechan. præſtantia in Com[illegible]n. Practic. where he endeavours to refute the Stahlians.

Juncker, who wrote according to Stahl's principles, does not deny that there is ſomething mechanical in the operation of *medicines* independently of the will or ſpontaneity of nature; but he aſſerts that their chief operation is owing to nature, which makes uſe of the remedy to attain its end. His words are, *Operationem medicamentorum ab ipſa naturâ gubernari innumeris confirmant obſervationes. Licet enim non negamus, ſubeſſe interdum actioni eorum aliquid mechanici, a naturæ arbitrio non pendentis, tamen hoc ita eſt habendum, ut operandi modus iſte maximo adhibito mercatur. Ad potiorem ſe determinatio, & naturæ uſitur remedio ad finem ſuum.* Juncker, Conſpect. Therap. p. 1, 2.

A late author obſerves, as to *medicines*, that let what diſeaſe ſoever be named, and any *medicine* as univerſally uſeful in it, yet he can ſhew circumſtances of patients, or of the diſeaſe, where that *medicine* would be very improper. He mentions ſeveral inſtances of this kind. See Medic. Eſſ. Edinb. vol. i. p. 267, ſeq.

A general idea of the manner wherein *medicines* operate on a human body, as explained by the ſect of mechanical phyſicians, may be conceived from what follows.

A few different ſorts of particles, variouſly combined, will produce a great variety of fluids; ſome may have one ſort, ſome two, ſome three, or more. If we ſuppoſe only five different ſorts of particles in the blood, and call them *a, b, c, d, e*, their ſeveral combinations, without varying the proportions in which they are mixed, will be theſe following; but whether more or leſs, need not be determined.

a b c: a d: a e:
b c: b d: b e: c d:
c e: d e: a b c: a d e:
a b d: a b e: a e c: a d e:
b d e: b d e: b e c: d e:
a b c d: a b e: a d e: a b d e: b d e: a b d e.

No theory of ſecretion has hitherto been able to give any tolerable account of the operation of ſuch *medicines* as promote an evacuation. For if the humours be equally mixed with the blood, that is, if the blood be in every part of the body the ſame, and its particles be not more apt to form certain humours in ſome certain parts of the body than others; or if they be not forced, by the power of ſome *medicine*, to form ſuch humours; then the quantities of humours, ſeparated in equal times, will always be as the velocity of the blood; but the velocity of the blood is ſeldom doubled by any *medicine*, and never tripled by the moſt acute fever. The quantity of the humour, however, drawn off by evacuating *medicines*, is often twenty times greater than the natural quantity; and therefore, upon ſuppoſition that the humours are everywhere equally mixed with the blood, the operation of evacuating *medicines* can never be accounted for.

Though this argument has the ſtrength of a demonſtration, yet there are ſome who explain the operation of purgative, and other evacuating *medicines*, by a ſtimulating faculty; whereby the ſluggiſh juices are not only forced out, but the obſtructed canals opened, and the motion of the blood quickened. But though ſuch a power be allowed, it would remain to be explained, why certain *medicines* do only ſtimulate certain glands? For it is evident, 1. That evacuating *medicines* have ſome other power, beſides the ſqueezing out ſtagnant juices; becauſe, when they are all ſqueezed out, they ſtill evacuate as much, if they be repeated, as they did before: as is plain, by continuing a ſalivation for many days. 2. We cannot ſuppoſe, that all bodies have every where, and at all times, juices ſtagnating; but theſe *medicines* conſtantly produce their effects, more or leſs, at all times. If the veſſels be ſuppoſed to be obſtructed, an evacuating *medicine* could but double the quantity that was evacuated before it was taken. 4. If theſe *medicines* operate only in theſe ways, then in a healthful body, where there were no obſtructions, they would have no effect at all. 5. If the removing obſtructions were the cauſe of a greater quantity evacuated, then the evacuation ſhould ſtill continue in a greater degree than before the obſtruction was removed; whereas, in fact, we conſtantly find it leſs, as the *medicine* works off. 6. Though a *medicine*, by ſtimulating a veſſel, may quicken the motion of the fluid in that veſſel; yet it can never increaſe the quantity of fluid running through it, in equal ſpaces of time; becauſe it quickens the motion of the fluid only by contracting the veſſel; and therefore the ſafter the fluid is made to run through the veſſel, the leſs fluid does the orifice of the veſſel admit; and conſequently, after the veſſel is contracted by the ſtimulating *medicine*, the ſecretion will be leſs, inſtead of being greater.

That a ſtimulus cauſes the part on which it acts to contract, is matter of fact; and alſo that purgative *medicines* do ſtimulate the bowels: but it may perhaps be likewiſe ſaid, they ſtimulate the heart and arteries, and increaſe their force, becauſe they not only quicken, but raiſe the pulſe; ſo that a greater quantity of blood is ſent to the glands of the guts. This may be granted; but not that it is the principal action of purgative *medicines*; becauſe that, by the ſame force, a greater quantity of blood is ſent to all the other glands of the body, whoſe fluids are not, however, ſenſibly increaſed; and the glands of the inteſtines receive a leſs quantity, in proportion, than any others, becauſe they cannot be ſo much dilated by the greater force of the blood, as others, which are not ſo much ſtimulated by the *medicine*.

There are others, who will have evacuating *medicines* endued with an attenuating quality, by which they diſſolve all the coheſions of the particles of the blood, and ſo ſet the ſeveral humours at liberty, to paſs through their proper glands; but if theſe *medicines* have a power univerſally to diſſolve all the coheſions of the blood, then every evacuating *medicine* would equally and indifferently increaſe the quantity of every ſecretion. Mercury would as conſtantly purge as ſalivate, and nitre promote perſpiration as well as urine; but this is repugnant to experience. If they have a power to diſſolve certain coheſions, and not others, this is but ſetting certain particles at liberty to paſs through their proper glands, which were not ſo before; and is a preparing the humours, in order to increaſe the quantity of ſecretion. Evacuating *medicines* muſt therefore have a power to affect ſome particles, and not others; that is, to repel ſome, and attract, retain, and alter others; and this is what may be affirmed to be in all *medicines*, and is what a thouſand chemical experiments demonſtrate.

The ſeveral humours then being formed, by the different coheſion of the particles of blood, the quantity of a humour ſecreted by any gland muſt be in a proportion compounded of the proportion that the number of the particles cohering in ſuch a manner as is proper to conſtitute the humour which paſſes through the gland, bears to the maſs of blood; and of the proportion of the quantity of blood that arrives at the gland. And hence it follows, that where there is a determinate quantity of a certain humour to be ſeparated, the number of particles that are proper to compoſe the ſecreted liquor, muſt be reciprocally proportional to the quantity of the blood that arrives at the gland; and therefore, if the quantity of ſecretion is to be increaſed, the number of particles muſt be increaſed; if the ſecretion is to be leſſened, the number of particles, proper for ſuch a ſecretion, muſt be leſſened in the ſame proportion.

Medicines, therefore, which can alter the coheſions and combinations of the particles, may either increaſe or diminiſh the quantity of any ſecretion. Thus, ſuppoſe a humour, which paſſes through the glands of the inteſtines, to be compoſed of three or four ſeveral ſorts of particles; that *medicine*, which will eaſily cohere to theſe particles

particles, and, by cohering, increaſe their mutual attractions, ſo as they may unite in greater numbers at, or before they arrive at the inteſtines, than they would have done, if the *medicine* had not been given, muſt neceſſarily increaſe the quantity of humour which paſſes through the glands of the inteſtines; if the quantity of blood which arrives at the glands, be not diminiſhed in the ſame proportion, as the number of particles is increaſed. After the ſame manner do diuretics, ſudorifics, and *medicines* which promote all other ſecretions, operate.

Why increaſing the quantity of ſome ſecretions ſhould diminiſh that of others, is not eaſy to explain on any other principle; for if the blood be equally mixed, in every part of the body, with all the humours which are ſeparated from it; that is, if the mixture of the blood be every where alike, ſo that every humour bears the ſame proportion to the reſt of the arterial blood in one part of the body that it does in another; and if every humour has its own proper gland through which it is ſeparated; then what is ſeparated by one gland is not ſubtracted from another, and conſequently does not diminiſh the quantity of humour which flows to this other, but does indeed rather increaſe the quantity of this other ſecretion: for the more any one humour is carried off, the greater proportion any other remaining in the blood, bears to the remaining blood; and therefore the more any one ſecretion is increaſed, the more all the reſt ſhould be increaſed likewiſe. But if all the humours be compoſed by a combination of a few different ſorts of particles, then the more apt theſe particles are to run into any one ſort of combination, the leſs all other combinations muſt be ſo; and conſequently the increaſing any one ſecretion muſt neceſſarily diminiſh the quantity of all others; but more eſpecially of that which has the moſt of the ſame ſort of particles. See SECRETION, HUMOUR, &c.

MEDICINES, *capital*. See CAPITAL.

MEDICINES, *chalaſtic*. See CHALASTIC.

MEDICINES, *hypochondriacal*. See HYPOCHONDRIACAL.

MEDICINES, *hyſteric*. See HYSTERIC.

MEDICINE-*cheſt*, is a portable cheſt, containing all ſorts of *medicines* neceſſary for a campaign or voyage, together with ſuch inſtruments as are moſt neceſſary and uſeful for the purpoſes of ſurgery.

MEDIETAS *Linguæ*, an inqueſt impanelled, whereof the one half conſiſts of natives or denizens, the other of aliens.

It is uſed in pleas, wherein the one party is a ſtranger, and the other a denizen. Solomon de Stanford, a Jew, in the time of Edward I. had a cauſe tried before the ſheriff of Norwich, by a jury of *ſex pecoris & ſeptem burnenſes, & ſex legales Judæos de civitate Norwici*. See JURY.

MEDIMNUM, *Μεδιμνος*, among the Greeks, a meaſure of capacity, holding ſix Roman *modii* or buſhels.

MEDINE, an Egyptian piece of money, of iron ſilvered over, and about the ſize of a ſilver three-pence.

MEDINUS, a name given by ſome to the MEDUS, a ſtone celebrated by the writers of the middle ages for many imaginary virtues.

MEDITATION, an act by which we conſider any thing cloſely, or wherein the ſoul is employed in the ſearch or conſideration of any truth.

In our religion, it is uſed to ſignify a conſideration of the objects and grand truths of the Chriſtian faith.

Myſtic divines make a great difference between *meditation* and *contemplation*: the former conſiſts in diſcurſive acts of the ſoul, conſidering methodically, and with attention, the myſteries of faith, and the precepts of morality; and is performed by reflections and reaſonings, which leave behind them manifeſt impreſſions on the brain. The pure contemplative have no need of *meditation*, as ſeeing all things in God at a glance, and without any reflection.

When a man, therefore, has once quitted *meditation*, and is arrived at contemplation, he returns no more; and, according to Alvarez, never reſumes the car of *meditation*, except when the wind of contemplation is too weak to fill his ſails.

MEDITERRANEAN, ſomething incloſed within land; or that is remote from the ocean.

MEDITERRANEAN is more particularly uſed to ſignify that large *ſea*, which flows between the continents of Europe and Africa, entering by the ſtreights of Gibraltar, and reaching into Aſia, as far as the Euxine Sea, and the Palus Mœotis.

The *Mediterranean* was anciently called the Grecian Sea, and the Great Sea. It is now cantoned out into ſeveral diviſions, which bear ſeveral names. To the weſt of Italy it is called the Ligurian or Tuſcan Sea; near Venice, the Adriatic; towards Greece, the Ionic and Ægean; between the Helleſpont and the Boſphorus, the White Sea, as being very ſafe; and beyond, the Black Sea, its navigation being dangerous.

The Britiſh trade carried on by means of the *Mediterranean* Sea, is of the laſt conſequence to Great Britain; and the permanent preſervation thereof depends on the poſſeſſion of the town and fortifications of Gibraltar.

The counterfeiting of *Mediterranean* paſſes for ſhips to the coaſt of Barbary, &c or the ſeal of the admiralty office to ſuch paſſes, is felony, without benefit of clergy. Stat. 4 Geo. II. c. 18.

MEDITRINALIA, among the Romans, feaſts inſtituted in honour of the goddeſs *Meditrina*, and celebrated on the thirtieth of September. They were ſo called from *medendo*, becauſe the Romans then began to drink new wine, which they mixed with old, and that ſerved them inſtead of phyſic.

MEDITULLIUM is uſed by anatomiſts for that ſpongy ſubſtance between the two plates of the cranium, and in the interſtices of all laminated bones.

MEDIUM, a Latin term, ſignifying *middle*, or MEAN.

MEDIUM, in *Logic*, or *medium of a ſyllogiſm*, called alſo the *mean*, or *middle term*, by the Italians *mezzo termine*, is an argument, reaſon, or conſideration, for which we affirm, or deny any thing: or, it is the cauſe why the greater extreme is attributed to, or denied of the leſs, in the concluſion.

Thus, in the ſyllogiſm, "Every good thing is to be "fired: but all virtue is good; therefore all virtue is to "be deſired:" the term *good* is the *medium*; *virtue* the leſs extreme, and *to be deſired* the greater.

It is called *medium*, as being a kind of mediator between the ſubject and predicate; or becauſe the extremes are ſo diſpoſed as to affirm, or deny, by means hereof. Some call it *argumentum tertium*, a third argument; and others ſimply *argumentum*, as being the cauſe why we aſſent to the concluſion.

Mediums, or *middle terms*, are the things principally ſought for, in diſcourſing; ſo that the invention of *mediums* makes the moſt eſſential part of logic. But the rules commonly given by logicians for that purpoſe, are mere impertinences. In effect, no ſuch rules can be given; nor have we any way of coming at ſuch *mediums* or reaſons, but by a cloſe attention to clear ideas.

MEDIUM, in *arithmetic*, or an *arithmetical medium*, or *mean*, called in the ſchools *medium rei*, is that which is equally diſtant from each extreme; or which exceeds the leſſer extreme, as much as it is exceeded by the greater, in reſpect of quantity, not of proportion.

Thus, nine is a *medium* between ſix and twelve.

MEDIUM, *geometrical*, or *mean*, called in the ſchools *medium perſonæ*, is that where the ſame ratio is preſerved between the firſt and ſecond, as between the ſecond and third terms; or that which exceeds in the ſame ratio, or quota of itſelf, as it is exceeded.

Thus, ſix is a geometrical *medium* between four and nine. See *Geometrical* PROPORTION.

This is a *medium* which virtue is ſuppoſed to obſerve; whence ſome call it *medium quoad nos*, as having a view to circumſtances, times, places, perſons, &c. Diſtributive juſtice obſerves a geometrical *medium*; commutative juſtice, an arithmetical one.

MEDIUM *participationis*, in the *Schools*, is that ſaid to be compounded of the two extremes. Thus, man, who is partly body, partly mind, is a *medium* by participation of the two extremes; ſo is warmth the *medium* of heat and cold, &c.

MEDIUM *negationis*, or *remotionis*, is that from which both extremes are derived; or, it is a ſubject capable of receiving both extremes, and yet not neceſſarily poſſeſſed of either.

In which latter ſenſe, the will is a *mean* with reſpect to virtue and vice; and the underſtanding, with reſpect to knowlege and ignorance.

MEDIUM *quod*, or *medium ſuppoſiti*, is ſomewhat between the agent and patient, which receives the action of the one, before it arrive at the other.

In this ſenſe, air is a *medium* between the fire and the hand heated thereby.

MEDIUM *quo*, is the form, or faculty, whereby an agent produces an effect: in which ſenſe, heat is ſaid to be the *medium* or *mean* whereby fire acts on the hand.

MEDIUM *ſub quo*, is that which renders the power to act complete, in general, without determining it to any particular object: in which ſenſe, light is the *medium* under which the eye perceives any colour.

MEDIUM *in quo*, is that, by inſpection whereof a power is produced in any thing, of knowing or perceiving another: ſuch is a ſpeculum, as it ſhews an object, an image, as it repreſents the reality, &c.

MEDIUM, in *Mechanical Philoſophy*, is that ſpace or region through which a body paſſes in its motion towards any point.

Thus ether is ſuppoſed to be the *medium* wherein the heavenly bodies move. Air the *medium* wherein bodies

move near our earth. And water is the *medium* in which fishes live and move. And glass is also a *medium* of light, as it affords a free passage.

That denſity or conſiſtence in the parts of the *medium*, whereby the motion of bodies in it is retarded, is called *the reſiſtance of the medium*; which, together with the force of gravity, is the cauſe of the ceſſation of the motion of projectiles.

MEDIUM, *ſubtile*, or *æthereal*. Sir Iſaac Newton makes it probable, that, beſide the particular aereal *medium*, wherein we live and breathe, there is another more univerſal one, which he calls an *æthereal medium*; vaſtly more rare, ſubtile, elaſtic, and active, than air; and by that means freely permeating the pores and interſtices of all other *mediums*, and diffuſing itſelf through the whole creation; and by the intervention hereof he thinks it is, that moſt of the great phenomena of nature are effected. See ÆTHER.

This *medium* he ſeems to have recourſe to, as the firſt and moſt remote phyſical ſpring; and the ultimate of all natural cauſes. By the vibrations of this *medium*, he takes heat to be propagated from lucid bodies; and the intenſeneſs of heat increaſed and preſerved in hot bodies, and from them communicated to cold ones.

By this *medium* he takes light to be reflected, inflected, refracted, and put alternately in fits of eaſy reflection and tranſmiſſion; which effects he alſo elſewhere aſcribes to the power of attraction; ſo that this *medium* appears the ſource and cauſe even of attraction.

Again, this *medium* being much rarer within the heavenly bodies than in the heavenly ſpaces, and growing denſer, as it recedes farther from them, he ſuppoſes the cauſe of the gravitation of theſe bodies towards each other, and of [illegible] towards the bodies.

[illegible] from the vibrations of this ſame *medium*, excited [illegible] from the eye by the rays of light, and thence [illegible] through the capillaments of the optic nerves [illegible] tory, he takes viſion to be performed; and ſo [illegible] from the vibrations of this or ſome other *medium*, excited in the auditory nerves by the tremors of the air, and propagated through the capillaments of thoſe nerves into the tenſory; and thus of the other ſenſes.

And again, he conceives muſcular motion to be performed by the vibrations of the ſame *medium*, excited in the brain at the command of the will, and thence propagated through the capillaments of the nerves into the muſcles; and thus contracting and dilating them.

The elaſtic force of this *medium*, he thews, muſt be prodigious. Light moves at the rate of conſiderably more than 70,000,000 miles in about ſeven minutes; yet the vibrations and pulſes of this *medium*, to cauſe the fits of eaſy reflection, and eaſy tranſmiſſion, muſt be ſwifter than light, which is yet 700,000 times ſwifter than ſound. The elaſtic force of this *medium*, therefore, in proportion to its denſity, muſt be above 490,000,000,000 times greater than the elaſtic force of the air, in proportion to its denſity; the velocities and pulſes of the elaſtic *mediums* being in a ſubduplicate ratio of the elaſticities, and the rarities of the *mediums*, taken together. And thus may the vibration of this *medium* be conceived as the cauſe alſo of the elaſticity of bodies.

Farther, the particles of this *medium* being ſuppoſed infinitely ſmall, even ſmaller than thoſe of light; if they be likewiſe ſuppoſed, like our air, to have a repelling power, whereby they recede from each other, the ſmallneſs of the particles may exceedingly contribute to the increaſe of the repelling power, and conſequently to that of the elaſticity and rarity of the *medium*, and ſo fit it for the free tranſmiſſion of light, and the free motions of the heavenly bodies. In this *medium* may the planets and comets roll without any conſiderable reſiſtance. If it be 700,000 times more elaſtic, and as many times rarer, than air, its reſiſtance will be above 600,000,000 times leſs than that of water; a reſiſtance that would make no ſenſible alteration in the motion of the planets in ten thouſand years.

And in not ſuch a *medium* better diſpoſed for the heavenly motions, than that of the Carteſians, which fills all ſpace adequately, and without leaving pores, and is vaſtly denſer than gold, and therefore muſt reſiſt more?

If any aſk how a *medium* can be ſo rare? let him tell how the air, in the upper regions of the atmoſphere, can be above a hundred thouſand times rarer than gold; how an electrical body can, by friction, emit an exhalation ſo rare and ſubtile, yet ſo potent, as though its emiſſion occaſions no ſenſible alteration in the weight of the body, yet it ſhall be diffuſed through a ſphere of two feet in diameter, and carry up leaf-copper, or leaf-gold, at the diſtance of a foot from the electrical body; or how the effluvia of a magnet can be ſo ſubtile, as to paſs a plate of glaſs without any reſiſtance or diminution of force; yet ſo potent, as to turn a magnetic needle beyond the glaſs.

That the heavens are not filled with any other, but ſuch a ſubtile æthereal *medium*, is evident from phenomena: whence elſe are thoſe laſting and regular motions of the planets and comets, in all manner of courſes and directions; and how are ſuch motions conſiſtent with that reſiſtance which muſt reſult from that denſe fluid *medium*, wherewith the Carteſians fill the heavens?

The reſiſtance of fluid *mediums* ariſes partly from the coheſion of the parts of the *medium*, and partly from the vis inertiæ of matter. The firſt, in a ſpherical body, is nearly as the diameter, or, at moſt, as the ſquare of the diameter, and the velocity of the body. The latter is as the ſquare of that factum. Thus are the two kinds of reſiſtance diſtinguiſhed in any *medium*; and, being diſtinguiſhed, it will be found, that almoſt all the [illegible] of bodies, moving in ordinary fluids, ariſes from inertiæ. The part which ariſes from the tenacity of the *medium*, may be diminiſhed, by dividing the matter into ſmaller parts, and making thoſe more ſmooth and slippery; but the other will ſtill be proportional to the denſity of the matter, and cannot be diminiſhed any other way, but by a diminution of the ſame.

Thus the reſiſtance of fluid *mediums* is nearly proportional to their denſities; and thus the air we breathe, being about nine hundred times lighter than water, muſt reſiſt about nine hundred times leſs than water; as, in effect, the ſame author has found it does by experiments on pendulums. Bodies moving in quickſilver, water, or air, do not appear to meet with any other reſiſtance but what ariſes from the denſity and tenacity of thoſe fluids; which they muſt, were their pores filled with a denſe and ſubtile fluid.

Heat, it is found, diminiſhes the tenacity of bodies very much; yet does it not decreaſe the reſiſtance of water, ſenſibly. The reſiſtance of water, therefore, ariſes chiefly from its vis inertiæ; conſequently, if the heavens were as denſe as water, or as quickſilver, they would not reſiſt much leſs: if abſolutely denſe, without any vacuum, be the particles never ſo ſubtile and fluid, they would reſiſt much more than quickſilver. A ſolid globe, in ſuch a *medium*, would loſe above half its motion, while it moves thrice the length of its own diameter; and a globe not perfectly ſolid, ſuch as the planets, would loſe more.

To make way therefore for the laſting motions of the planets and comets, the heavens muſt be empty of all matter, except, perhaps, ſome very fine effluvia, from the atmoſpheres of the earth, planets, and comets; and ſome ſuch æthereal *medium* as we have deſcribed. A denſe fluid can ſerve for no purpoſe, in the heavens, but to diſturb the celeſtial motions, and make the frame of nature languiſh; and in the pores of bodies, it can only ſerve to check the vibrating motion of their parts, wherein their heat and activity conſiſts. Such a *medium*, therefore, unleſs we had ſome evidence of its exiſtence, muſt be given up; and, that given up, the hypotheſis of light's conſiſting in a preſſion falls alſo to the ground.

MEDIUM, in *Botany*, a name given by Dioſcorides to the violet, and by Lobel to the ſea-ſtag-flower, *or lris marittima Narbonenſis*.

MEDIUM *ſeptum*. See SEPTUM.

MEDIUS *venter*, in *Anatomy*, denotes the breaſt or THORAX.

MEDIUS, *Glutæus*. See GLUTÆUS.

MEDLAR, *meſpilus*, in *Botany*, a genus of the *monandria pentagynia* claſs. Its characters are theſe: the empalement of the flower is permanent, of one leaf, cut into five ſpreading concave ſegments; the flower is compoſed of five roundiſh, concave petals, which are inſerted in the empalement; the number of ſtamina is different in the different ſpecies, from ten to twenty or more, which are alſo inſerted in the empalement; the germen is ſituated under the flower, and ſupports an uncertain number of ſtyles, from three to five; it afterward becomes a roundiſh oval berry, carrying the empalement on its top, and incloſing four or five bony ſeeds. Linnæus enumerates ſeven, and Miller twenty-two ſpecies.

We have two kinds of *medlar* propagated very frequently in orchards, for the ſake of their fruit; the one is the common *medlar*, or, as it is called by ſome, the Nottingham *medlar*; the other, the Dutch *medlar*. Miller makes theſe two varieties of the ſame ſpecies. The firſt of theſe was once almoſt the only kind known in England; but ſince the other has been introduced, it is found to much ſuperior in the ſize and flavour of the fruit, that it is now almoſt the only kind thought worth the cultivating. They are propagated by budding or grafting them upon the hawthorn, or the pear-ſtock, upon either of which they take very well, and may be afterwards tranſplanted into the fruit-garden, either as ſtandards, or trained up againſt an eſpalier, in both which methods they will ſucceed very well. If the larger ſort are trained up in an eſpalier, the fruit will be much larger; but great care muſt

must be taken in the pruning, not to shorten the bearing branches, for the fruit is almoſt all produced at the extremities of theſe. The *medlar* will grow on any ſoil; but on a moiſt and ſtrong ſoil the fruit will grow larger, and on a dry one it will, though ſmaller, be much better taſted.

The fruit ſhould be ſuffered to remain on the branches till October, at which time it will begin to fall of itſelf, and it ſhould then be gathered in the middle of a dry day, and laid up in a dry place till ſoft, and beginning to decay, which is uſually about a month after it is gathered; at this time they are fit for eating; for, till they begin to decay, they are too harſh for the palate.

Medlars are cooling, drying, and binding, eſpecially before they are ripe; and are uſeful in all kinds of fluxes. The ripe fruit eaten too freely is ſubject to bind the ſtomach, and cauſe the colic. The lapilli, or hard ſeed, are accounted good for the gravel and ſtone: they are an ingredient in the *ſyrupus myrtinus*. Miller's Bot. Off.

MEDLAR, *paſſion-bramble*. See SERVICE-*tree*.

MEDLEY. See CHANCE-*medley*.

MEDULLA *oſſium*, or *marrow of the bones*, is a ſoft fatty ſubſtance, placed in the cavities or pores of divers bones. See MARROW.

The *medulla* is incloſed in a membrane, and is devoid of ſenſe: it is red in the greater cavities, white in the leſs, and ſoft and ſucculent in ſpongy bones.

From this is ſecreted the MEDULLARY *oil*.

MEDULLA *cerebri* and *cerebelli*, denotes the white ſoft part of the brain and cerebellum, covered on the outſide with the cortical ſubſtance, which is of a more dark or aſhy colour. See the origin, ſtructure, and uſe thereof, under BRAIN, and CEREBELLUM.

MEDULLA *oblongata*, is the *medullary* part of the brain and cerebellum, joined in one; the fore-part of it coming from the brain, and the hind-part from the cerebellum. See *Tab. Anat.* (*Oſteol.*) *fig.* 5. *lit. d. d.*

It lies on the baſis of the ſkull, and is continued through the great perforation thereof into the hollow of the vertebræ of the neck, back, and loins; though only ſo much of it retains the name *oblongata*, as is included within the ſkull. After its exit thence, it is diſtinguiſhed by the name of *medulla ſpinalis*.

The ſubſtance of the *medulla oblongata*, being only an aggregate of thoſe of the brain and cerebellum, muſt, like them, be purely fibrous or nervous, and only an aſſemblage of minute tubes for the conveyance of the animal ſpirits. It ariſes, as it were, from four roots; whereof the two largeſt ſpring from the brain, and are called *crura*; the two leſſer from the cerebellum, which Dr. Willis calls *peduncuſi*.

Upon inverting it, the firſt thing that appears upon its trunk is a protuberance, ſomewhat like a ring, and for that reaſon called *protuberantia annularis*. Then follow ten pair of neſves, which have their origin here, and are hence ſent to the ſeveral parts of the body. Immediately under the firſt pair, or the olfactories, appear two ſmall arteries, or branches, of the carotides. The ſecond pair, or optics, being cut off, there appears the infundibulum, which ends in the glandula pituitaria, and, on each ſide, the carotid arteries enter the ſkull. In the lateral ventricles of the *medulla* are two prominences on each ſide, the one pair called *corpora ſtriata*, from the appearance of ſtripes, or nervous fibres, within them; their outer ſubſtance being cortical or glandulous, like the reſt of the ſurface of the brain, though not ſo deep. Betwixt the *corpora ſtriata* is a broad thin production of the *medulla*, called *fornix*; and underneath them lie two other prominences, called *thalami nervorum opticorum*. On either ſide of theſe is a plexus of blood-veſſels, called *plexus choroides*. And under the fornix a narrow aperture, called the *vimen*, which lets into the infundibulum; which is a paſſage from the third ventricle to the glandula pituitaria, through the *medulla* of the brain; being lined with the pia mater. Under this, in the ſinus called *ſella turcica*, or *turrica*, upon the os cribroſum, is the glandula pituitaria; which is ſurrounded with a plexus of veins, called *rete mirabile*, only viſible in brutes. On the hind-part of the third ventricle is a ſmall foramen, called *anus*, leading to the fourth ventricle of the cerebellum; at the orifice of this is ſeated a ſmall gland, which, from its fancied reſemblance to a pine-apple, is called *cumerium*, or *glandula pinealis*; where Deſcartes and his followers imagine the ſeat of the ſoul to be. On the backſide of the *medulla oblongata*, near the cerebellum, are four protuberances, whereof the upper and larger are called *nates*, the under and leſſer *teſtes*. Between theſe and the proceſſes of the cerebellum, is the fourth ventricle, from its figure called *calamus ſcriptorius*. On the *medulla oblongata*, near its extremity, are four other prominences, two on each ſide, called CORPORA *pyramidalia*, and OLIVARIA.

MEDULLA *ſpinalis*, or the *ſpinal marrow*, is a continuation of the *medulla oblongata*, or *medullary* part of the brain, without the ſkull.

It conſiſts, as the brain does, of two parts, a white or *medullary*, and a cineritious or glandulous one; the former without, and the other within. The ſubſtance of the exterior part is much the ſame with that of the corpus calloſum, only ſomewhat tougher, and more fibrous; which difference becomes the more apparent, as it deſcends the lower, on account of the ſtraightneſs of the cavity, which, growing gradually more narrow, preſſes the *medullary* fibres cloſer together, and renders them more compact, and gathers them into more diſtinct faſciculi, till, having deſcended the whole tract of the ſpina, they end in the cauda equina. It is the origin of moſt of the nerves of the trunk of the body: it ſends out thirty pair on each ſide to the limbs, the great cavities, and other parts; which are nothing but faſciculi of *medullary* fibres, covered with their proper membranes.

The *ſpinal marrow* is generally ſaid to be covered with four coats: the firſt, or external one, is a ſtrong nervous ligament, which ties the vertebræ together, to the inſide of which it firmly adheres. The ſecond is a production of the dura mater; it is exceedingly ſtrong, and ſerves to defend the *ſpinal marrow* from any hurt from the flexures of the vertebræ.

The third is a production of the arytænoides, and is a thin pellucid membrane, lying between the dura and pia mater, or the ſecond and fourth membranes of the *medulla*. This membrane gives a coat to the nerves that go out of the ſpina, which is the inner membrane of the nerves, as the dura mater gives the outer. The fourth coat is a continuation of the pia mater, and is an extremely fine, tranſparent membrane, ſtrictly embracing the whole ſubſtance of the *medulla*, dividing it in the middle into two tracts, and making, as it were, two columns of it. See *Tab. Anat.* (*Oſteol.*) *fig.* 6.

In ſhort, the ſpinal marrow does not run through the middle of the vertebræ, as it does in other animals, but is carried through a whole ſeries of the apophyſes, which ſtand on the upper part of the bone, and are therefore called the *apophyſes ſcandentes*, to diſtinguiſh them from the others, which their ſituation occaſions to be called the lateral and ventral. All theſe dorſal apophyſes of the vertebræ are hollow at their baſe, and by that means afford a continued channel for this marrow. The baſes of the lower apophyſes, reaching from the anus to the tail, have alſo the ſame ſort of hollow at their baſe; but this ſerves only for the paſſage of the larger blood-veſſels.

MEDULLARY *oil* is no more than the finer and more ſubtile parts of the *medulla*, or marrow of the bones. See MARROW and OIL.

This, Dr. Havers obſerves, paſſes not into the bones through ducts, but by ſmall pores formed into veſicles or glandules, which are conglomerated into diſtinct lobules, contained in ſeveral membranes inveſting the whole marrow; all which veſicles or bags are propagated from the outward coat of the arteries; and by theſe it paſſes from one to another, till it arrives at the ſides, or extreme parts, of the bone. That part of it, which is ſupplied to the interſtices of the joints, goes into them by paſſages, penetrating through the bone into thoſe cavities, and formed for that end. The uſe of this oil is either common to all the bones, whoſe temper it preſerves, and keeps from being too brittle; or more peculiarly to the joints, where it is very ſerviceable: 1. To lubricate the bones at their extremities, that they may move more eaſily and free. 2. To keep the ends of the articulated bone from growing hot with motion. 3. To preſerve the joints from wearing by attrition, and rubbing one againſt another. And, 4. To preſerve the ligaments of the joints from dryneſs and rigidity, and to lubricate thoſe parts which ſlide upon the bones, and keep the cartilages, which are joined to them, flexible.

MEDUS, or MEDINUS, a name given by the writers of the middle ages to a ſtone brought from Media, of which they ſay there were two kinds, the one black, and the other green. They attribute many ſtrange virtues to theſe ſtones; the black they ſay was a fatal poiſon when taken inwardly, but that if wetted with milk, and rubbed upon the ſkin of a woman with child, it cauſed her to bring forth a boy. This, and a number of other as probable virtues, did theſe ignorant and fanciful writers beſtow at pleaſure on ſtones never known to the world before, and of which themſelves gave no deſcriptions. This ſeems to be only a falſe hiſtory of the *media* of Pliny.

MEDUSA, in *Natural Hiſtory*, the name of a genus of inſects, of the order of GYMNARTHRIA.

The body of the *meduſa* is of an orbiculated convex figure, of a gelatinous ſubſtance, and not hairy; the tentacula, or the plicæ, which ſerve inſtead of them, are ſituated in the center of the under part of the animal.

Authors have described them under the names *urticæ marinæ*, and *pulmones marini*. See URTICA *marina*.

Mr. Banks, in his passage from Madeira to Rio de Janeiro, discovered a new species of the *medusæ*, which, when brought aboard by the casting net, had the appearance of metal violently heated, and emitted a white light. With these animals were taken small crabs of three different species, altogether new, each of which gave as much light as the glow-worm, though the creature was not so large by nine tenths. These luminous animals gave that appearance to the SEA, which has been mentioned by many navigators, and of which various reasons have been assigned. It appeared to emit flashes of light exactly resembling those of lightning, only not so considerable, but so frequent, that sometimes eight or ten were visible at the same moment.

MEDUSA'S *head*, in *Botany*. See STURDE.

MEDUSÆ *caput*, in *Natural History*, a name given by authors to the *stella marina*, called by some, from its various branchings, *stella arborescens*. Rumphius, Gesner, and many other authors, have described this strange fish in its recent state; and in the Acta Eruditorum, we have an accurate figure, and a very remarkable account of one which was found fossil, and preserved in a remarkably perfect manner in stone.

The stone in which it was found was of the fissile or flaty kind; and it was so large as to extend over a piece of this stone of four feet in length, and between three and four in breadth. The body of the fish, from which all the rest seemed originally to have arisen, lay at one corner of the stone, and the arms extended themselves lengthways in very distinct and natural manner the whole length of the stone; and from these there parted, on every side, other smaller ones, and these were finally divided into parts more minute, in such a manner as to represent the most painting. Act. Erudit. ann. 1725. p. 377.

The study of fossils is more improved by this single specimen than by thousands of others, and by the reasonings of almost as many authors. The fossils called *entrochi*, have always perplexed the writers on these subjects to account for; some having judged them a sort of stony vegetables; some, *lusus naturæ*; and others, as different things; but in this table the whole fish is so perfectly preserved, that there can remain not the least doubt of its being really the *stella arborescens*; and in this both the figure and author's words express, in the plainest manner possible, that the long arms or branches reaching from one end to the other of the stone, are composed of a number of *entrochi* as it were, tied together in the same manner as the single joints of those *entrochi*, which we meet with, are to one another; or, in plain fact, that our *entrochi*, which have perplexed us so much to account for their origin, are in reality the fragments of the arms or branches of this fish. These branches in this famous specimen, were composed of what we call *trochitæ*, and had many rudiments of smaller branches, as well as perfect ones, growing from their sides, and would have been so many common *entrochi*, if broken off.

What was most remarkable in this fossil was, however, the separating of smaller branches which ran entire to their ends, and there terminating in an infinite number of small ramifications, all growing from one head, they formed clusters of four or five inches in diameter, and of an inconceivable beauty, resembling the compound flower of some elegant plant. The matter of the large branches, when examined, appeared to be the same with that of the common *entrochi*, that is, spar. The author calls it *joculites*, but that was a word indeterminately used by authors, till of late, for all plated and bright fossils.

It is plain that this complete fish could have no way come into this stone but at the time when it was yet moist and soft; and the author calls it *novum diluvii monumentum, a new remembrancer of the deluge*.

MEDUSA *caput*, or MEDUSA'S *head*, in *Ancient Mythology*, occurs frequently both on the breast-plates and shield of MINERVA; in some of which it is the most beautiful, and in others the most shocking object. In some figures the face is represented as dead, but with the most perfect features that can be conceived; in others, her face is full of passion, and her eyes convulsed; and in many others, the look is altogether frightful, and formed on purpose to inspire terror. The beauties and horrors of *Medusa*'s face are mentioned by the Roman poets. Ov. Met. iv. ver. 793. Lucan, lib. ix. ver. 680. Virg. Æn. viii ver. 438. Spence's Polymetis, p. 61.

MEEKNESS, in *Ethics*, is a virtue which consists in bearing affronts, reproaches, and injuries, with a due composure of mind. Its opposite vice is *revenge*.

MEER, in *Mining*, a space containing twenty-nine yards in length in any vein.

MEER-*scale*, in *Mining*, is a pin of wood drove into the superficies of the earth, to shew the extent or end of a *meer* of ground.

MEER-*swine*, in *Zoology*, a name given by some to a sea-fish, more usually known by the name of *caprisicus*. See GOAT-*fish*.

MEETER. See METRE.

MEGADOMESTICUS. See DOMESTIC.

MEGÆRA, in *Mythology*, one of the three FURIES. She is represented with serpents on her head, and two distinguished ones over her forehead, as her sisters have, and, like them, with torches. She is not mentioned so frequently by the Roman poets as the others are. Virgil gives us a descriptive picture of her, where he is speaking of the punishment of the Lapithæ; who were said to be always placed round a table very richly and plentifully set out, with a loose piece of rock hanging over their heads, as just ready to fall; and this Fury attending close by, to watch and menace them, the moment they endeavoured to taste any one of the tempting things set before them. Æn. vi. ver. 607.

MEGALARTIA, Μεγαλαρτια, in *Antiquity*, a festival in honour of Ceres, being the same with THESMOPHORIA.

MEGALASCLEPIA, Μεγαλασκληπια, in *Antiquity*, a festival in honour of Æsculapius. See ASCLEPIA.

MEGALENSIA, or MEGALESIA, in *Antiquity*, solemn feasts celebrated among the Romans on the twelfth of April, in honour of the great mother of the gods, that is, Cybele or Rhea; wherein were sports or combats held before the temple of that goddess.

They were called *megalensia*, from the Greek μεγαλη, *great*; Cybele being accounted the great goddess.

MEGAMETER. See MICROMETER.

MEI *missura*. See MISERERE.

MEIDANS, in the *Eastern Nations*, are a sort of country-seats, where the greater people have often summer-houses, to which they retire on the three days of the week in which they do not attend the *pasha*'s divan, and where they divert themselves with seeing their slaves ride, shoot, and throw the dart, while they are regaling with their pipe and coffee.

MEINOR. See MAINOUR.

MEIOSIS, in *Rhetoric*, is a figure, which is a species of the HYPERBOLE.

MEL. See HONEY.

MEL *cedrinum*, in the *Materia Medica of the Ancients*, a term used to express a sort of liquid manna, used rather as a pleasant sweet in foods than as a medicine, and which seems to have been the same with the *mel roscidum* of Galen, and with the liquid manna of mount Sinai; that mountain having been the place where it was annually collected in large quantities, even in Galen's time; and the account Bellonius gives of the manner of collecting it in his time, agreeing very well with what Galen has left about it. It is, however, an error in Bellonius, to suppose this to be the *terenjabin* of the Arabians, that being evidently a solid, not a liquid substance, and being from all accounts the same with what is now called MANNA *Persicum*, or Persian manna.

The *mel cedrinum* is a term used only by Hippocrates for this substance, and seems so odd, that many are apt to believe there is an error in the text, and that the author never meant any such thing. Foesius is of opinion, that these ought to be read as two distinct names, with a comma between them, and that the author only meant by them two substances very well known in his time, which were common honey, and the liquid substance called *cedrinum*, or CEDRIA.

MEL *roscidum*, in the *Materia Medica of the Ancients*, a name given to a kind of liquid manna collected in their time, as it is at present, in considerable quantities, on mount Sinai. The monks who collect it call it *terenjabin*, after the name of a kind of manna, common among the Arabians. But this is an error, the terenjabin of those authors not being a liquid manna, but the small round kind, collected from the *albagi maurorum*, and now called *manna Persicum*. It does not appear that the *mel roscidum*, or any other species of manna, was used in medicine by the ancients; this was esteemed a curiosity, rather than a thing of any use, by Galen; and other authors say, it was sweeter than honey itself, with no farther account; whence it seems rather to have been used as a delicacy than as a medicine. See TERENJABIN, and MANNA *Persicum*.

MELA, a surgeon's instrument, called also SPECULUM, and by the vulgar, a PROBE.

Its use is to probe ulcers, or draw a stone out of the penis: its form is various, according to the use it is intended for.

MELALEUCA, in *Botany*, a genus of the *polyadelphia pentandria* class: the characters of which are, that the empalement is divided into five segments; the flower has five petals, and many filaments joined together in five bodies; the style is single, and the fruit is a three-celled capsule, containing three cells, and half covered with a berried empalement. There is only one species.

MELAM-

MELAMPODIUM, in *Botany*, a genus of the *syngenesia polygamia necessaria* class: its characters are, that the receptacle is chaffy and conical; the down is single-leaved and concave, and the empalement is composed of five leaves. There are two species.

MELAMPYRUM. See *Cow-Wheat*.

MELAN *pharmacon*, a word used by Hippocrates, and by some supposed to mean common writing ink. He orders this to be poured upon the cranium, in case of a fissure, in order to discover how far it has penetrated. Galen seems to refer to this, in some places, and mentions his having treated of it in his book of ulcers; but as no such medicine is found prescribed there, it is probably one of the lost compositions of the ancients. In the spurious edition of Hippocrates his book treating on the diseases of women, there is a black medicine ordered to be made of the squamæ and flos æris.

MELANAETOS, in *Ornithology*. See *Black* EAGLE.

MELANCHOLY, formed from μελας, *black*, and χολη, *bile*, in *Medicine*, a low kind of delirium, without a fever; usually attended with fear, heaviness, and sorrow, without an apparent occasion. Or, as some define it, a disease which consists in the perturbation or injury of the imagination, which prevents it from forming a regular and determinate idea of things, as at other times; so that its due operations are interrupted, and often fecond ideas, having no connection with the first, crowd in, and are succeeded by actions no way analogous to that first idea, and therefore appearing irrational.

The ancients attributed this disease to black and cloudy spirits, arising as vapours from a redundant atrabilary humour.

Some of the moderns ascribe it to the irregular motion of the spirits, and their acid constitution; and others, who seem to know it better, to too heavy and viscid a blood, which permits not a sufficiency of spirits to be separated in the brain, to animate and invigorate the nerves and muscles: lastly, others attribute it to a thinefs of the meninges of the brain.

Some enumerate two species of *melancholy*; the erratic, and the apoplectic.

The erratic *melancholy* is that species of the disorder, which most generally seizes patients in the month of February. It is so called, because those who labour under it cannot remain for an hour in one place, but continually wander about, without knowing where they go. It is by the Arabians called *kunbuth*, from an animal, which, as they inform us, perpetually moves up and down on the surface of stagnant waters.

The opposite of this erratic *melancholy* is the apoplectic *melancholy*; for as in the former the patients are restless, and wander about from one place to another, so in the latter every circumstance is reversed; for the patients appear stupid, and, being apparently destitute of a locomotive faculty, seem to be fixed to a particular place.

Authors distinguish *melancholy* into three kinds; the sad, the merry, and the mixt, partaking of the nature of both; but in all these the cause is the same, and the difference is only owing to the temperament and habit of the patient.

This distemper has, however, its more essential differences, on account of the causes from which it is produced. In some people, it seems wholly to depend upon a false prefiguration and judgment of things in the mind; and in this case it is usually habitual and incurable. In others it arises from injuries of the body; and in these it always is observed to bear a proportion to the injury or debility of the parts. This peculiar species is called hypochondriac *melancholy*; and finally, in others, it seems of a mixt nature; as when it has taken its first origin from distemperatures in the body, but is afterwards so increased by mental disorders, that even after the total removal of the corporeal ones, it still remains in all its force upon the mind. This is a too common, and very unhappy case.

This disease is varied an infinite number of ways, according to the temperament and ideas of the person affected with it. It is a species of madness, and only differs from a downright mania in degree.

Signs of it. These are a perpetual anxiety of mind, without any rational cause; a distaste and dislike to every thing, even before it comes in sight, and often a weariness even of life itself. A frequent weeping for imaginary causes, or for no cause at all. Many people, in this case, seem always to want room; they are for opening all the windows they can, and for running out into the streets or fields, thinking themselves every where imprisoned; others leave their houses, and dread being taken up for capital offences, though never guilty of any; and in others, these distemperatures of the mind are evidently joined with others of the body, such as palpitations of the heart, sighing very deeply, painful respiration, strictures of the tonic motions of the parts, tremblings, paleness of the countenance, and extenuation of the body. Sometimes, instead of these restrictions, there are frequent remissions of the same tonic motions, whence arise sudden flushings of the face, uncertain heats in the body, and a general lassitude and loss of strength. In most cases of this kind, there is an obstinate costiveness of the bowels, and the affections of the mind are increased by terrible watchfulness; and if the persons sleep a little, they are terrified with troublesome dreams all the while; if of sanguine habits, they are continually dreaming of blood, of battles, and of fires; and if of phlegmatic constitutions, of water and drowning. Dreadful apprehensions happen also between sleeping and waking, and they usually awake in agonies, with violent tremblings, and difficulty of respiration. In the merry *melancholy*, the alienations of the patient's mind are employed about chearful, and often obscene ideas; and sometimes their fancy exalts them to the state of kings and princes.

Persons subject to melancholy. These are principally men of great learning, and of sedentary lives, hypochondriac people, and such as are troubled with disorders of the spleen; and to these are to be added women subject to hysteric complaints.

Causes of it. These are principally a spissitude of the blood, and a detention of it about the vena portæ; a bad disposition of the internal parts, as a schirrous or ulcerous constitution in them, or an actually ulcerated state. Persons who are afflicted with *melancholy* from these causes, are usually subject to very unruly passions, and those of various kinds; love, fear, dejection of spirits, despair, and anger, are often very predominant in them.

A suppression of the hæmorrhoidal discharges in men, and of the menstrual ones in women, will also frequently throw them into this distemper; as will also an over-great application to study, especially on abstruse subjects; a conscientious dread from past crimes; continual disappointment in the expectations; and sometimes a timorous disposition, brought on in infancy, by the folly of nurses.

Prognostics in it. That kind of *melancholy* which is brought on by immaterial causes alone, such as that arising from too intense study, or other imaginations or effects of the mind, is always much more obstinate and difficult of cure than that which depends upon material causes, and has its origin in a distempered state of the body. The hypochondriac *melancholy* is the most easy of all to be cured, especially if the hæmorrhoidal discharges can be brought on regularly again; yet even these cases must be taken in time; for when the *melancholy*, even from such causes, is become habitual, it will remain after the cause is removed which gave them origin.

Method of treatment. Melancholy, when it depends on immaterial causes, requires physic for the mind rather than for the body; and the frequent conversation with an ingenious friend, of a calm and quiet disposition, will go farther towards a cure than a thousand medicines. Persons in this state must be as little thwarted or contradicted as possible; and whips and chains are to be avoided, unless in cases of the most extreme necessity: this is also a method equally necessary in those cases where habit has confirmed upon the mind that disorder, which at first arose merely from material causes. But when the disease not only arises, but as yet depends entirely upon material causes, the cure is easy, and is to be performed in the following manner. The primæ viæ are to be cleansed by purges, particularly those made of black hellebore; and after this the patient is to be blooded in the foot, taking away about six ounces; then the blood is to be attempered by giving, three or four times a day, powders composed of purified nitre, and the common abstorients; and after a due use of these, the parts are to be restored to their pristine tone and vigour by the milder chalybeates; the greatest care must also be taken to bring the hæmorrhoidal discharges in men, and the menstrual ones in women, to a natural and proper state; and then a sufficient quantity of weak liquors drank at meals, and a moderate degree of exercise, will bring the patient usually to an absolute state of *health*.

Hypochondriac *melancholy* always is more relieved by bleeding than by any other practice; and indeed all attempts of a cure are vain, if this be not first done; purified nitre, dissolved in small quantities in all the patient's drink, will, *in time*, be found to do great things alone, as to a cure. It is the practice of some persons to give vomits in these cases; but they often turn *melancholy* into a true MANIA.

There is a lower species of *melancholy*, called low spirits, to which persons of weak nerves are more or less subject. Generous diet, the cold bath, exercise, and amusements, are the most likely means to remove this complaint. It is much increased by solitude, and indulging gloomy

ideas, but may often be relieved by chearful company and ſprightly amuſements. When low ſpirits are owing to a weak, relaxed ſtate of the ſtomach and bowels, an infuſion of the Peruvian bark, with cinnamon or nutmeg, will be proper. Steel joined with aromatics may likewiſe be beneficial; but the greateſt advantage is to be expected from riding, and a proper diet. When this diſorder ariſes from a foulneſs of the ſtomach and inteſtines, or obſtructions in the hypochondriac viſcera, aloetic purges will be proper. The Harrowgate ſulphur has been ſometimes ſerviceable in this caſe. When low ſpirits proceed from a ſuppreſſion of the menſtrual or hæmorrhoidal flux, theſe evacuations may be reſtored, or others, as iſſues, ſetons, &c. ſubſtituted in their place. Dr. Whytt obſerves, that nothing has ſuch ſudden good effects in this caſe as bleeding. When low ſpirits have been occaſioned by long continued grief, anxiety, or diſtreſs of mind, relief muſt be ſought from agreeable company, variety of amuſements, and change of place. Perſons afflicted with this diſorder ſhould avoid every kind of exceſs, eſpecially of venery, and ſtrong liquors. Buchan's Dom. Med. p. 485, &c.

MELANCHOLY *thiſtle*. See THISTLE.

MELANCHOLY *tree*, *myſtanthus*. See *Arabian* JESSMIN.

MELANCHORYPHUS, in *Natural Hiſtory*, the name of a bird, in the neſts of which, the ancients tell us they found the caſſais or turquoiſe. This ſeems a very ridiculous ſtory, and the whole to be only founded on the reſemblance of colour between that ſtone and the eggs of this bird. It has been alſo diſputed among authors, what was meant by the *melancoryphos* of the ancients; the general opinion is, that it was that little bird which, from the blackneſs at the top of the head, we call the *black-cap*. But the ancients themſelves ſeem to have meant ſomewhat larger bird by it; for they tell us, that the ſiccdula, at a certain time of the year, changed colour, and became the *melancoryphos*, or black-crown. There is no great foundation for ſuch an opinion as this, but it may, however, ſerve to ſhew, that theſe two birds were much of a ſize.

MELANOCERASUS, a name given by ſome botanical authors to the *ſolanum lethale, or bella-donna*, a poiſonous ſort of nightſhade, with a beautiful berry, reſembling a large black cherry.

MELANOGOGUES, Μελανωγωγα, formed from μελας, *black*, and αγω, *to draw*, are ſuch medicines as are ſuppoſed particularly to purge off atra bilis or black choler. But there is no ſuch ſpecies of choler now regarded; and conſequently this diſtinction of evacuants is but little uſed.

MELANOPIPER, in the *Materia Medica*, a name given by ſome writers to the common black PEPPER.

MELANTERIA, in *Natural Hiſtory*, the name of a foſſil ſubſtance, much talked of by the ancient writers in medicine, and ſuppoſed by moſt of the moderns to have been loſt among the later ages. This, however, is an erroneous opinion; for it is really produced at this time in many parts of the world, though its reſemblance to ſome of the other foſſils, in its external appearance, has made it almoſt univerſally overlooked by the writers on theſe ſubjects. It is, in its moſt perfect ſtate, a very beautiful ſubſtance, of a cloſe, even, and regular texture, moderately heavy, and of a very beautiful yellow, like that of the fineſt gold. It is, in this ſtate, found in looſe irregular lumps, never very large, being uſually only from an ounce to two ounces in weight, and of a ſmooth, even, and poliſhed ſurface. This is the caſe when it is pure and ſolid, and it is then alſo of as bright and fine a colour on the outſide as within.

This is a ſtate, however, in which it is very rarely found; we uſually meet with it either in the form of a downy efflorescence on various ſpecies of vitriolic minerals, particularly on the common marcaſites and pyrites; or elſe in looſe, ſhattery, and friable maſſes, of rough ſurfaces, of a ſpongy texture, and of a coarſe duſky yellow; in either of theſe ſtates, however, it ſo much reſembles a more or leſs pure native ſulphur, that it is generally miſtaken for that body. It makes no effervescence with acid menſtruums; and when put into the fire, is found not to be inflammable, but calcines firſt to a whitiſh, and finally to a ſtrong red colour.

Water diſſolves a part of its ſubſtance, and this may again be procured ſeparate from the liquor, by evaporation and cryſtallization, and then it appears in form of rhomboidal bluiſh-green cryſtals.

It is found in the mines of ſome parts of the Hartz-foreſt in Germany, and is often met with on the ſides of hills in many parts of the Eaſt Indies, and in America; it is uſually miſtaken in all theſe places for a native ſulphur. Hill's Hiſt. of Foſſ. p. 627.

MELANTZANA, in *Botany*, a name given by many authors to the MAD-*apple*, called more uſually *melangena*.

MELANTHIUM, in *Botany*, a genus of the *hexandria trigynia* claſs: its characters are, that the flower has ſix petals, and that the filaments proceed from the elongated claws of the flower.

MELANURUS, in *Ichthyology*, the name of a fiſh caught in the Mediterranean, and ſometimes, though rarely, in the Britiſh ſeas, and called by ſome writers *oculata*, and *ocellata*.

It is of an oblong and rounded body, and its back very little prominent, and of a bluiſh-black; its ſides are of a ſilvery-white, but are variegated with duſky tranſverſe ſtreaks; it ſeldom exceeds five or ſix inches in length; and its tail has a remarkable black ſpot in it, whence it has its name, as it has that of *ocellatus*, from the likeneſs of its eyes.

MELAGNES, a word uſed by certain authors for a black kind of worm found in meadows, in the month of *May*, which, when bruiſed, emits an agreeable ſmell. Some alſo have called a ſmall ſpecies of beetle by the ſame name.

MELAS, μελας, *black*, is an epithet applied by ancient authors in medicine, in a peculiar ſenſe, to the colour of the ſkin; and alſo, to ſome particular remedies. In conformity hereto, in the firſt place, a perſon who has a black or fable colour preternaturally diffuſed over his ſkin, as in the black jaundice, is called *melanchrous*, or *melanchroi*.

MELASMA, a fugillation, or black mark, from a bruiſe.

MELASSES. See MOLOSSES.

MELASTOMA, in *Botany*. See *American* GOOSEBERRY-*tree*.

MELCHITES, in *Eccleſiaſtical Hiſtory*, were thoſe Chriſtians in Syria, Egypt, and the Levant, who, in the ſeventh century, though not Greeks, followed the doctrines and ceremonies of the Greek church. They were called *melchites*, i. e. *Royaliſts*, from the Hebrew *Melech*, *king*, by their adverſaries, by way of reproach, on account of their implicit ſubmiſſion to the edict of the emperor Marcian, in favour of the council of Chalcedon. For the ſame reaſon the emperor Juſtinian had the epithet Chalcedonenſis given him.

MELCHIZEDECHIANS, or MELCHISEDEKIANS, ancient ſectaries, ſo called, becauſe they raiſed *Melchizedec* above all creatures, and even above Jeſus Chriſt.

The author of this ſect was one Theodotus; whence the *Melchizedechians* become more commonly known by the name of Theodotians; all the difference between thoſe and the ſtrict Theodotians, conſiſting in that particular article relating to *Melchizedec*; who, according to them, was the great and ſupreme virtue.

This ſect was revived in Egypt towards the cloſe of the third century by Hierax. See HIERACITES. Thoſe alſo in later times, who have maintained, that *Melchizedech* was the ſon of God in a human form, may be diſtinguiſhed by this appellation. See Cunæus de Rep. Hebræorum.

MELDFEE, in our *Old Writers*, a recompence due and given to him that made the diſcovery of any breach of penal laws, committed by another perſon, called the promoter's or informer's fee.

The word is Saxon, from *meldfeoh*.

MELEAGRIS, in *Ornithology*. See TURKEY.

MELEAGRIS *Nicandri*. See GUINEA-*hen*.

MELECH, a word uſed by ſome of the chemical writers to expreſs SALT.

MELECHIL, a word ſometimes uſed as the name of the gum BDELLIUM, and ſometimes as that of the fruit of a tree of the palm-kind, much uſed by the ancients as a cordial and reſtorative. The word *melech* has the ſame double ſenſe, and both are, by the more accurate writers, determined in their meaning by the epithets annexed to them, the gum *bdellium* being called *melechil*, or *melech Judaicum*, and the fruit *melech methaſe*; yet the conſequence even of this has been more confuſion: for the later writers ſuppoſed, that the fruit was not produced by a palm-tree, but by the ſame tree which produced the gum.

MELEGEION, a word uſed by ſome writers in medicine to expreſs a fetid matter, of the conſiſtence of honey, diſcharged from old ulcers.

MELES, in *Zoology*. See BADGER.

MELET, in *Ichthyology*, a name uſed by ſome for a ſmall tranſparent ſea-fiſh, called by authors, HEPSETUS and *anguilla*, and by ſome ATHERINA.

MELETIANS, in *Eccleſiaſtical Hiſtory*, the name of a conſiderable party, who adhered to the cauſe of *Meletius*, biſhop of Lycopolis, in Upper Egypt, after he was depoſed about the year 306, by Peter, biſhop of Alexandria, upon the charge of his having ſacrificed to the gods, and having been guilty of other heinous crimes; though Epiphanius makes his only failing to have been an exceſſive levity againſt the lapſed. This diſpute, which was at firſt a pet-

personal difference between Meletius and Peter, became a religious controversy; and the *Melitian* party subsisted in the fifth century, but was condemned by the first council of Nice.

MELIA, *Μηλέα*, of the Greek writers, the name of a vegetable that often occurs in the Greek naturalists, and which has so many significations, that it is not easy to understand the authors, without being well acquainted with them. All late writers have perplexed the world by miscalling things, and thence rendering names synonymous and confused, which were at first clear and distinct; but the confusion of the senses of the word *melia* is as old as the earliest writers we are acquainted with: Theophrastus complains of it in his time.

The most common use of the word is for the *fraxinus*, or ash-tree. The ancients used to make the handles of their spears and darts of this, and therefore they sometimes called them *melea*. This word was also used as the name of a seed, called also by some, *meline*. This was of the nature of panic, and by some confounded with the panic. Suidas mentions this as different from the panic; but Diocles seems to have made them the same seed. Pliny has translated the passage from Diocles, and by an unaccountable error, has called the plant *melfrugum*, and says, that it has the same virtues with millet.

MELIA, in *Botany*, the name by which Linnæus calls the AZEDARACH, or BEAD-tree.

MELIA *terra*, in *Natural History*, a name given by some authors to the *melinum*, or white earth of the island of Melos, used among the ancients in painting; but in the works of Dioscorides and Galen signifying a substance of a very different kind; the MELINUM of the painters having been a *marle*, and the *melia terra* of the physicians a tripela.

The *terra melia* of Dioscorides, and the ancient physicians, is a dry loose and harsh earth, found in masses of different size, and lodged among the looser strata of other matter, never making a stratum of itself. It is very firm and hard, of a pale greyish white or light ash-colour, very heavy, of a loose, open, and spungy texture, and of a rough, uneven, and dusty surface. It adheres slightly to the tongue, and does not stain the hands, and leaves a dust after the handling, which is so harsh as to make a grating noise, when the fingers are afterwards rubbed together. It makes no effervescence with acids. It is found in all the islands of the Archipelago, and was used by the ancients for the same purposes with the pumices. Hill's Hist. of Foss. p. 68.

MELIANTHUS, in *Botany*. See HONEY-*Flower*.

MELICA, in *Botany*, a name given by some authors to the plant which produces the *furgum*, or *Indian* MILLET.

MELICA, in the Linnæan system of *Botany*, a genus of the *triandria digynia* class: the characters of which are, that the empalement has two valves, and is composed of two flowers; and that the rudiment of the flower is lodged among the small flowers. There are five species.

MELICA is also a word used by the ancients as the name of a food of a refrigerating and moistening quality. It seems to have been a kind of *ptisana*; for Galen, when he directs persons of a hot habit to use a refrigerating diet, among other aliments of that kind, directs the eating of *melica*, which, he says, is prepared of milk. Constantine, in his book of Agriculture, mentions *melica*, and says it was made by pouring milk into an earthen vessel, first well impregnated with boiling hot vinegar, by means of which there was a separation of the milk into whey and curd.

MELICERIOLA, a diminutive of the word MELICERIS, a small encysted tumour.

MELICERIS, *Μηλίκηρις*, a tumor, or abscess, inclosed in a cystis; consisting of matter not unlike honey: whence its name. The *meliceris* is otherwise called ATHEROMA. It gathers without pain, and gives way upon pressure, but returns again: it is to be cured by warm discutients.

MELICHLORUM, in *Natural History*, a name given by some of the ancient writers to a species of jasper, of a greenish-yellow, usually found variegated with other colours.

MELICOCCA, in *Botany*, a genus of the *octandria monogynia* class: its characters are, that the empalement is divided into four segments; that the four petals are reflexed below the calyx; that the stigma is subpeltated, and the fruit a coriaceous drupe. There is only one species.

MELILOT, in *Botany*, a species of TREFOIL: *melilot* grows naturally among corn in many parts of England, where it is a troublesome weed; and ripening about the same time with the corn, is often ground with it, being difficult to separate from it: in such case it spoils the bread, or whatever the flour is used for, by giving it a strong taste, like the plaster made from it.

Melilot is scarce ever given internally; but used externally, it is a great emollient, resolvent, and digestive. It is a good ingredient in glysters, cataplasms, and fomentations of this intention. The flowers are recommended by some in infusion, in the manner of those of chamomile, as a remedy for the *fluor albus*. It formerly gave the name to one of the officinal plasters, which received from the *melilot* a green colour and an unpleasant smell, without any addition to its efficacy.

MELINTZANIUM, in *Botany*, a name given by the later Greek writers to the plant called *strychnos* by the earlier writers of that nation. Theophrastus and all the old Greeks, use the word *strychnos*, and say there are three kinds, two of which are poisonous, and the other not. The first causing madness, the second causing sleep, and the third bearing an efculent fruit. This last is the plant we call *pomum amoris*, the fruit of which is at this time eaten by many people.

Fuchsius confesses that he does not know what to make of the word; but it is wonderful that the similitude of sound between this and the *melangcana* and *melongena* did not lead him to the knowlege of what it was, as he was acquainted with those words.

MELINUM, in *Natural History*, the name of an earth, famous in the earliest ages of painting, being the only white of the great painters of antiquity; and, according to Pliny's account, one of the colours with which alone they performed all their works.

It is a fine white marly earth, of a very compact texture, yet remarkably light; a sort of texture which must render any earth fit for the painter's use, that is of a proper colour. It is frequently found forming a stratum in the earth, lying immediately under the vegetable mould. It is of a very smooth, but not glossy surface; is very soft to the touch, adheres firmly to the tongue, is easily broken between the fingers, and stains the skin in handling. It melts readily in the mouth, and is perfectly fine, leaving not the least gritiness between the teeth. Thrown into water, it makes a great bubbling and loud hissing noise, and moulders away into a fine powder. It does not ferment with acids, and suffers no change in the fire. These are the characters by which the *melinum* of the ancients is distinguished from all the other white earths. It is still found in the same place from whence the painters of old had it, which is that from whence it has its name, the island of Milo, called Melos by the Greeks, and is common in most of the adjacent islands. It has been of late tried here as a paint, and is found not to make so bright a white as the other substances now in use among the painters, but seems not liable, like them, to turn yellow; and if so, would be worth the consideration of persons in the colour-trade, especially as it may be had in any quantities for carriage. Hill's Hist. of Fossils, p. 45.

MELINUS *color*, *Μήλινος χρώμα*, in *Antiquity*, a colour often mentioned in speaking of the habits of players. It was a reddish yellow, or the colour of ripe apples, in Greek called *μῆλα*, and their colour *μηλινος χρώμα*.

MELISSMATICO *ſpiti*. See SPITE.

MELISSA, in *Botany*. See BALM.

MELITENSIS *terra*, *earth of Malta*, in the *Materia Medica*, an earth of which there are two very different kinds, the one of the genus of the bole, the other of the marles. The latter is that known by medicinal authors under this name: the former is the Malta earth now in use: but both being brought from the same place, are confusedly called by the same name.

The Maltese bole, which is what we use now, is a fine earth, of a close compact texture, and very heavy; when dug, it is of a very pure white, but it is apt to contract a yellowness in drying, and become of a cream colour. It is of a very smooth and shining surface, scarce at all stains the skin in handling, adheres strongly to the tongue, and melts into a butter-like substance in the mouth. It makes no effervescence with aqua fortis, or any other acid menstruums, and suffers no change of colour in the fire. Hill. The Maltese marle, which is the *terra Melitensis* of medicinal authors, is a loose, crumbly, and very light earth, of an unequal and irregular texture, and, when exposed to the weather, soon falls into fine soft powder; but when preserved and dried, it becomes a loose light mass, of a dirty white colour, with a greyish cast: it is rough to the touch, adheres firmly to the tongue, is very easily crumbled to powder between the fingers, and stains the hands. Thrown into water it swells, and afterwards moulders away into a fine powder. It ferments very violently with acid menstruums.

Both kinds are found in great abundance in the island of Malta, and the latter has been much esteemed as a remedy against the bites of venomous animals, but with how much justice we cannot say. The other has supplied its place in the German shops, and is used there as a cordial, a sudorific, and astringent. Hill.

MELITTES, *Μελίτης*, in *Natural History*, an indurated clay, of a yellowish colour, but in many respects approaching to the nature of the moroctbus or French chalk;

which, when pulverized, yields with water a milky liquor, of a taſte ſomewhat like honey: whence it takes its name.

It is a ſmooth ſubſtance, of a compact texture and great weight, of a fine, even, gloſſy ſurface, ſmooth and ſoft to the touch, does not adhere to the tongue, nor ſtain the fingers; but drawn along a rough ſurface, leaves a fine ſlender white line, and ſhaved into very thin pieces, has ſome degree of tranſparence. It does not ferment with acids, and burns to a pure white.

It is found in mines of metals, and ſeems to partake pretty much of the nature of lead; having a ſweetneſs ſomewhat like that of the ſal ſaturni, but much fainter. It only differs from the galactite, in that it is milder to the taſte. See GALACTITES. The ancients uſed it in inflammations of the eyes, and to dry ulcers.

They alſo applied it externally in ulcers, and gave it inwardly as a ſpecific to people who were to ſuffer pain, ſuppoſing it would make them leſs ſenſible of it. It is at preſent very common in Italy, and probably in many other places, but is not known or regarded.

MELILITES *lapis*, a name given by ſome authors to ſome of the rounder ſpecies of *echinitæ*, from their reſembling an apple in their ſhape.

MELILTIS, *baſtard baum*, or *baum-leaved archangel*, in *Botany*, a genus of the *didynamia gymnoſpermia* claſs: its characters are, that the empalement is broader than the tube of the flower; the upper lip of the flower is plane, the lower crenated, and the antheræ cruciated. There is only one ſpecies.

MELITTOMA, a word uſed by the ancients to expreſs a ſort of ſweet-meat, or confection, made with pleaſant ingredients mixed in honey.

MELIUS *inquirendum*, in *Law*, a writ which lieth for a ſecond inquiry to be made of what lands and tenements a man died ſeiſed, where partiality is ſuſpected upon the writ called *diem clauſit extremum*.

MELLAGO, a word uſed by medicinal writers to expreſs any medicine that has the conſiſtence and ſweet taſte of honey. It is often applied to the rob, or inſpiſſated juice of fruits, mixed with ſugar in the making.

MELLE, or MULLI. The Peruvians, by gently rubbing the fruit of this tree between their hands in warm water, deprive it of all its ſweetneſs; after which they ſtrain the liquor, and leaving it a few days to ſubſide, it becomes a very tranſparent drink, and by boiling becomes an excellent kind of honey.

MELLEGUETTA, in the *Materia Medica*, a name uſed by ſome authors for the great cardamom, commonly called grain of paradiſe.

MELLINE, in *Botany*, a name given by many of the ancient writers to the garden-plant we call BAUM. It had the name *melline* from its yielding honey to the bees.

It has many other names, derived from the ſame ſource; ſuch as *apiaſtrum*, from *apis*, the bee, *melliphyllum*, the honey leaf, and from this, *melliſſophyllum*. Many alſo are of opinion, that the *amello* of Virgil is the ſame plant.

MELLISODIUM, a word uſed by ſome chemical writers to expreſs burnt lead.

MELLITTA, in *Natural Hiſtory*, the name of a genus of the *echini marini*, of the general claſs of the placentæ. The characters of the *mellita* are, that they are plain and flatted ſhells, with their edges arched and waved, and have on their ſuperficies two or more oblong apertures, which reach to the baſe. Of this genus there are two known ſpecies: 1. A ſmooth one with a circular vertex. 2. A ſcutellated kind, reſembling the ſhell of the tortoiſe, and with a pentagonal vertex. See *Tab. of Teſtaceous Animals*, N° 9.

MELOCARPUS, a word uſed by ſome of the old authors to expreſs the fruit of the ARISTOLOCHIA, or *birthwort*, uſed in ſome external applications.

MELOCHIA, in *Botany*, a genus of the *monadelphia pentandria* claſs: its characters are, that it is pentagynous, and that the fruit is a five-celled ſingle-ſeeded capſule. Linnæus reckons ſix ſpecies: Miller makes this genus a ſpecies of the corchorus or *Jew's*-MALLOW.

MELODY, *Melodia*, compounded of *μελος*, *honey*, and *ᾠδη*, *ſinging*, in *Muſic*, is the agreeable effect of different muſical ſounds, ranged or diſpoſed in a proper ſucceſſion.

Melody is the effect only of one ſingle part, voice, or inſtrument; by which it is diſtinguiſhed from *harmony*; though in common ſpeech, theſe two are frequently confounded.

Harmony is properly the agreeable reſult of the union of two or more concording muſical ſounds heard in conſonance, i. e. at one and the ſame time; ſo that harmony is the effect of two parts at leaſt: as therefore a continued ſucceſſion of muſical ſounds produces *melody*, ſo does a continued combination of theſe produce harmony.

Though the term melody be chiefly applicable to the treble, as the treble is chiefly diſtinguiſhed by its air; yet ſo far as the baſs may be made *airy*, and to ſing well, it may be alſo properly ſaid to be *melodious*. Of the twelve harmonical intervals of muſical ſounds, diſtinguiſhed by the names of *ſecond leſſer*, *ſecond greater*; *third leſſer*, *third greater*; *fourth*; *falſe fifth*, *fifth*; *ſixth leſſer*; *ſixth greater*; *ſeventh leſſer*, *ſeventh greater*, and *octave*; all *melody*, as well as harmony, are compoſed: for the octaves of each of theſe are but replications of the ſame ſound; and whatever is ſaid of any or all of theſe ſounds, is to be underſtood alſo of their octaves.

MELODY, *for the rules of*. See COMPOSITION.

MELOE, in *Botany*. See *Oil* BEETLE.

MELOLANTHUS, the name of a peculiar ſort of beetle, which is found in all parts of England, and in many other countries among trees and hedges. The French call them *hannetons*, and we *cock-cheſters*, *dorrs*, and by many other names. The name *melolanthus* is as old as Ariſtotle, and is given this creature from its feeding on the bloſſoms of the crab or wild apple. We have, of late years, had great damages done by the grubs of theſe beetles working under ground; but in Ireland they have been uſed to come in ſwarms, in certain years, in the beetle ſtate, and have been ſo terrible to that country, that the people have called them locuſts.

The firſt time they are remembered by authors to have appeared in this vaſt abundance, in that country, was in the year 1683. They then appeared in the ſouth-weſt part of the county of Galway; they appeared firſt upon the coaſt, and were brought by a ſouth weſt wind, a wind ſo common there, that it may almoſt be called the trade-wind of Iceland; from the coaſt they ſoon ſpread over the inland parts of the county, and were ſeen every where in ſuch numbers, as were ſcarce to be conceived. They never ſtirred in the day time, but were ſeen covering the leaves and branches of trees and hedges, and in many places hanging down in prodigious cluſters on one another's backs, in the manner of bees when they ſwarm. As ſoon as the ſun ſet, they uſed to leave the hedges, &c. and take wing, gathering in bodies, and making a humming confuſed noiſe like that of drums at a diſtance. They ſometimes formed bodies together, that darkened the air for three or four miles ſquare. They flew ſo low ſometimes, that it was ſcarce poſſible for a perſon going along, to make his way through them; and by ſtriking againſt the faces and necks of women and children, they did much miſchief, every one leaving a mark behind it; and thoſe of this ſex or age, who had been among them, came home all over bruiſes.

This, however, was little to the miſchief they did the fields; for though the middle of the ſummer was the ſeaſon in which they came, they had, in a few days eaten up all the leaves of the trees ſo completely, that they all looked as bare as in the depth of winter. The noiſe they made, while eating in vaſt numbers together, was like that of ſawing timber. The gardens fared no better than the hedges, for they eat up leaves, young ſtalks, and fruit, and every thing that was green and ſoft there, and left only a parcel of naked ſticks behind them. Many of the trees, thus ſtripped, wholly periſhed. Phil. Tranſ. N° 234.

MELOMELI, a word uſed by the ancients, to expreſs honey impregnated with quinces.

MELON, *melo*, in *Botany*, a ſpecies of the CUCUMBER, the Linnæan ſyſtem. Its characters are theſe: it hath male and female flowers on the ſame plant; the male flowers have a bell-ſhaped empalement of one leaf, whoſe border is terminated by five awl-ſhaped briſtles, and one bell-ſhaped petal, faſtened to the empalement, and cut into five ſegments at the brim; it hath three ſhort ſtamina inſerted in the empale-ment, joined together; two of which have bifid points: the female flowers have no ſtamina or ſummits, but have a very large oval germen, ſituated below the flower, which turns to an oval fruit with ſeveral cells, filled with oval, acute-pointed, compreſſed ſeeds, incloſed in a ſoft pulp. There is a great variety of this fruit cultivated in different parts of the world, many of them of no value, ſize being regarded too much in the markets. That ſort called the Cantaleupe *melon*, ſo called from a place in the neighbourhood of Rome, where this fruit has been long cultivated, and whither it was brought from Armenia, is in the greateſt eſteem among the curious in every part of Europe.

Beſides this, there are alſo the Romana, the Succado, the Zatte, the ſmall Portugal or Dormer, and the black Galloway *melons*, moſt of which are cultivated for an early crop.

The proper management and culture of *melons* are as follow: the ſeeds ſhould be procured from good *melons*, of the ſoundeſt ſort and higheſt flavour, produced, as ſome have adviſed, in a diſtant garden; for if ſowed on the place where it was raiſed and ripened, it is very apt to degenerate. This ſeed ſhould be kept three years before it is ſowed, but not more than ſix, and it ſhould be ſowed at two ſeaſons, or if at three, it will be ſtill better: the firſt for

for the early crop, to be raised under frames, ſhould be ſown about the middle of February; the ſecond to be raiſed in the ſame manner, is to be ſowed about the middle of March; and thoſe which are deſigned for hand or bell-glaſſes, or to be covered with oil-papers, ſhould not be ſown till about a week in April.

For thoſe of the firſt ſeaſon, the ſeeds may be ſown on the upper ſide of a cucumber-bed, if there be any; or, a proper quantity of new looſe dung muſt be provided, and thrown on a heap to ferment, and turned over, that it may acquire an equal heat, and the plants muſt be raiſed and managed like CUCUMBERS, until they are planted where they are to remain. The beds or ridges, where the plants are to remain, ſhould be placed in a warm ſituation, ſo that they may be defended from all cold and ſtrong winds, and incloſed in a good reed fence. In preparing the earth for theſe plants, the Dutch and German gardeners form a mixture of a third part of hazel loam, a third part of the ſcouring of ditches and ponds, and the ſame quantity of very rotten dung; which they mix up at leaſt one, and often two years, before they make uſe of it, frequently turning it over, ſo that the parts may be well incorporated; but the compoſt in which Mr. Miller has found *melon* plants to ſucceed beſt in England is two-thirds of freſh gentle loam, and one-third of rotten neat's dung: if theſe are mixed together one year before it is wanted, ſo as to have the benefit of a winter's froſt and ſummer's heat, obſerving to turn it over often, and never ſuffering weeds to grow upon it, this will be found equal to any compoſt whatever. Before the plants appear, there ſhould be a quantity of new dung thrown in a heap, allowing about fifteen wheelbarrows full to each light; which muſt be turned over two or three times, and in a fortnight it will be fit for uſe; when the trench muſt be dug to receive the dung, where the bed is deſigned to be made, which in a dry ground ſhould not be leſs than a foot, or a foot and a half deep. The frames ſhould then be placed over the bed to keep out the wet; but no earth ſhould be laid upon it for three or four days, till it is found of a proper temperature of heat. When this is the caſe, the earth may be laid upon it, about two inches thick, except in the middle of each light, where the plants are to be pinced, which muſt be raiſed into a hill, fifteen inches high or more, terminating in a flat cone: in two or three days after the earth is put on the bed, it will be of a proper temper to receive the plants; which ſhould be carefully taken up with a trowel, ſo as to preſerve all the fibres of their roots; or, if the beds cannot be ready for them in time, ſoon after the third or rough leaf is put out, it will be a good method to put each plant into a ſmall pot while they are young, and theſe may be plunged into the hot bed where they were raiſed, or in a cucumber-bed, where there is room; and when the bed is ready, the plants may be turned out of the pots, with the whole ball of earth to their roots: and this is the beſt method for the Cantaleupe *melon*. When the plants are placed on the top of the hills, they ſhould be gently watered once or twice, till they have taken good root; and when they are well fixed in the new beds, a greater quantity of earth ſhould be laid on the beds, preſſed down as cloſe as poſſible, and raiſed at leaſt a foot and a half thick upon the dung all over the bed; obſerving alſo to raiſe the frames, that the glaſſes may not be too near the plants, leſt the ſun ſhould ſcorch them. When the plants have four leaves, the top of the plants ſhould be pinched off with the finger and thumb, that they may put out lateral branches for producing the fruit; and when two or more of theſe lateral ſhoots are produced, they muſt alſo be pinched to force out more. The management of theſe beds is much the ſame as that of cucumbers; except that *melons* require more air, and very little water. In five or ſix weeks the plants will ſpread over the bed, and reach to the frames, when the alleys between the beds ſhould be dug out; or in caſe of one bed, a trench ſhould be made on each ſide, about four feet wide, as low as the bottom of the bed; and hot dung wheeled in for a lining, to the ſame height as the dung of the bed; this ſhould be trodden down cloſe, and covered with the ſame earth that was laid on the bed, to the thickneſs of a foot and a half or more, treading it down as cloſe as poſſible. In this way the bed will be extended to the width of twelve feet, that the roots of the plants may ſpread quite through it; and the beds will alſo require a freſh warmth, which will be of great ſervice in ſetting of the fruit. When the vines have extended ſo as to fill the frames, and want more room, the frames ſhould be raiſed up with bricks about three inches high, to admit the ſhoots of the vines to run out under them. When the fruit appears, the vines ſhould be carefully looked over three times a week; and one ſhould be choſen upon each runner, that is ſituated neareſt the ſtem, having the largeſt foot ſtalk, and appearing to be the ſtrongeſt fruit; then pinch off all the other fruit which may appear upon the ſame runner; and pinch off the end of the runner at the third joint above the fruit; and if the runner is gently pinched at the next joint above the fruit, it will ſtop the ſap, and ſet the fruit. There is alſo another method practiſed by ſome gardeners to ſet this fruit, which is the taking off ſome of the male flowers, whoſe farina is juſt ripe and fit for the purpoſe, laying them over the female fruit, and gently ſtriking with the naile the male flowers, to ſhake the farina into the female flowers; whereby they are impregnated, and the fruit will ſoon after ſwell, and manifeſt viſible ſigns of being perfectly ſet; ſo that where the plants are under frames, and the wind excluded from them, which is wanted to convey the farina from the male to the female flowers, this practice may be very neceſſary. The glaſſes of the hot-bed ſhould alſo be raiſed high, to admit a large ſhare of air to the plants, otherwiſe the fruit will not ſet; and if the ſeaſon ſhould prove very warm, the glaſſes may be frequently drawn off, eſpecially in an evening, to receive the dews, provided there is little wind ſtirring: but they ſhould not remain off the whole night, leſt the cold ſhould prove too great. When the plants have extended themſelves from under the frames, in cold weather their extremities ſhould be covered every night with mats, and the plants ſhould be watered once in a week in dry warm weather, in the alleys between the beds.

For thoſe *melons* that are raiſed under bell or hand-glaſſes, the plants ſhould be raiſed in the manner already directed, and about the latter end of April, in a forward ſeaſon, the beds may be made. For this purpoſe, a ſufficient quantity of hot dung ſhould be provided, allowing eight or nine good wheelbarrows of dung to each glaſs. For one bed extended in length, the trench ſhould be dug out three one-half feet wide, and of ſuch a length that the glaſſes may not be placed nearer than four feet to each other: in digging the trench, it ſhould be ſo ſituated, as to allow for the widening of the bed three or four feet on each ſide; the depth muſt depend on the nature of the ſoil, and when there is no danger of the beds being injured by the wet, the lower it is made, the better. When the dung, prepared as before, is laid on the bed, there ſhould be a hill for each plant, one foot and a half high, and the other part need not be covered more than four inches thick; the glaſſes ſhould then be placed over the hills, and in two or three days after the beds are made they will be fit for receiving the plants, which ſhould be removed in the manner already directed. Theſe plants muſt be watered at firſt, to ſettle the earth to their roots, and ſhaded every day, till they have taken new root; and if the nights prove cold, it will be proper to cover the glaſſes with mats, in order to preſerve the warmth of the bed. If ſeveral beds are made, they ſhould be placed at eight feet diſtance from each other. When the plants have taken good root, their tops muſt be pinched off, and the pruning muſt be the ſame as for thoſe under frames. In the day-time, when the weather is warm, the glaſſes ſhould be raiſed on the oppoſite ſide to the wind, to admit freſh air to the plants; and when they reach the ſides of the glaſſes, in favourable weather, the glaſſes muſt be ſet up on three bricks, that the vines may have room to run out under them; but when this is done, the beds ſhould be covered all over with earth to the depth of one foot and a half, and trod down as cloſe as poſſible; and in cold nights, the beds ſhould be covered with mats. And as the vines of the Cantaleupe *melons* cannot bear wet without injury, it will be neceſſary to arch the beds over with props, to ſupport the mats, that they may be ready for covering at all times when they require it. If the weather ſhould prove cold, hot dung may be laid to theſe beds in the manner directed for thoſe under frames. Some have lately raiſed their *melons* with conſiderable ſucceſs, under oiled paper; but great care muſt be taken not to keep theſe coverings too cloſe over them. And Miller adviſes to bring up the plants under hand or bell-glaſſes, till they begin to extend themſelves under the glaſſes, and, then, inſtead of the covering of mats, to put over them the paper, done over with linſeed oil.

The farther management of *melons*, after their fruit is ſet, is to keep pulling off all the ſuperfluous fruit, and to pinch off all weak runners; and alſo to turn the fruit gently twice a week, that each ſide may have equal benefit of the ſun and air. When the fruit is fully grown, care ſhould be taken to cut it at a proper time; for if it is left a few hours upon the vines, it will loſe much of its delicacy; therefore the vines ſhould be looked over at leaſt twice in a day: and if the fruit intended for the table is cut early in the morning, before the ſun has warmed it, it will be much better flavoured. but if it ſhould be neceſſary to cut any afterwards, it ſhould be put into cold ſpring water or ice, to cool it, before it is brought to table; and that cut in the morning ſhould be

kept

kept in the coolest place till it is used. The signs of this fruit's maturity are, its beginning to crack near the foot stalk, and its beginning to smell, which never fail: but the Cantaleupe *melons* seldom change their colour till they are too ripe. Miller.

Mr. Reynolds has communicated to the Society of Arts, the following method of raising *melons*, without earth, dung, or water. About a month before the seeds are sown, he prepares a bed of cast-off tanner's bark, four feet deep, six feet wide, and twelve feet in length: this he covers with four lights, so as not to admit rain or water. Marcl, he says, is a proper season for this purpose. When the bed becomes warm, which generally happens in about twenty days, a few *melon*-seeds are put into warm milk, in an earthen vessel, which is pressed down into the bark-bed, where it remains thirty-six hours, in order to promote the vegetation of the seeds. Then at equal distances he directs to open four holes in the bed, each nine inches in diameter, and five inches deep: having in readiness about a peck of pounded bark, like saw-dust, some of it to be put at the bottom of the holes, to the thickness of three inches: on this bark some of the seeds are to be placed, and pressed down with the fingers; then the seeds are covered with two inches more of the powdered bark, pressing the whole down with the hand. When the plants are advanced to a proper size, the best are chosen, and the others cast away; those that are reserved are ordered to be properly pruned, and to have as much warm air as possible during the summer. In this way, he says, he has raised as good *melons* as can be desired.

When a *melon* is perfectly fine, it is full, without any vacuity: this is known by knocking upon it; and when cut, the flesh must be dry, no water running out, only a little dew, which is to be of a fine red colour. Large *melons* are not to be coveted, but firm and well-flavoured ones. Our gardeners who raise *melons* for sale, sow the seeds of the larger rather than the good kinds, and they increase the size of these by much watering the roots; but this spoils the taste. Some of the French raise at this time particularly fine *melons*, by a method kept as a secret, but which we find, on a strict inquiry, is no other than the ingenious Mr. Quintiny's, of that nation, published near eighty years ago in our Philosophical Transactions.

The *melons* particularly proper to be treated in this manner, are those which have a thin and somewhat embroidered skin, not divided by ribs, and have a red pulp, dry and melting on the tongue, not mealy, and of a high flavour. These are what succeed in the following method, and are greatly improved in size and flavour by it.

When the seeds of this *melon* are placed in the ground, the first thing that appears is a pair of seminal leaves, or ears, as the gardeners call them. Between these two leaves there shoots, some days after, a leaf called the first leaf, or knot; and out of the same place, after some days more, there shoots another leaf, called the second knot. Out of the midst of this stalk of the second knot, there shoots a third knot: this third knot must be cut off at its insertion, without hurting the branch of the second knot from whence it grows. Out of this place there will grow, after this cutting, a branch, which will be what the gardeners call the first arm; and this arm will, in the same manner as the first plant, shoot out, first one, then a second, then a third knot; this third knot must be cut again as before, and thus the third knots are all along to be cut off, and arms or branches will grow up in the places of them, all the way in the same manner as the first; and it is at those arms that the *melons* will be produced; and they will be always good, if the foot or root be well nourished in good earth, and cherished by a good hot bed and the sun. The foot of the *melon* must never be suffered to pass into the dung, and the earth must not be watered but moderately, when it is seen to grow too dry; but in this case, it must be moderately moistened in time, lest the shoot suffer by it. Twice or three times a week is often enough to water in the driest weather, and this must always be done about sunset; and when the heat of the sun is too violent, the *melons* must be covered with straw-mats from eleven in the morning to about two in the afternoon. When it rains much, the *melons* must also be covered, lest it hurt them by too much moisture. Phil. Trans. N° 45.

If the root produce too many branches, the weakest are to be cut off, and only three or four left; and those which are left are to be such as have their knots closest to one another. When the plants are removed from the seed-bed to the place where they are to stand, if they are very strong, they should be planted single; but if otherwise, two are to be set in each hole.

When they are planted single, the two branches, which always grow on each side from the base of the seed-leaves, are to be left on; but when two plants are set together, these branches are to be cut off, otherwise all the branches will be too numerous, and they will entangle and spoil one another.

When the *melons* are knit, two of them only are to be left upon each foot, choosing those which are best placed, and next to the first and principal stalk, that is, to the heart of the foot. None but fair fruits are to be left, and such as have a thick and short tail; and the foot of the *melon* must be short, well trussed, and not far distant from the ground. *Melons* of a long stem, and having the stalk of the leaf too long and slender, are never vigorous.

All the superfluous branches must be cut off from time to time, as they shoot out.

There sometimes shoots out a branch more than is here mentioned, between the two seed-leaves or ears. If this is strong and vigorous it is to be kept on, but if weakly, it is best to take it off, for it will never bear good fruit.

MELON-*seed*. We read of *melon*-seeds thirty-three years old, vegetating and producing a fine number of plants. Phil. Trans. N° 475. sect. 6. and in N° 464. we read of *melon*-seeds forty-three years old, producing fruit.

Melon-seed is cooling and diuretic, and has the same virtues with the other cold seeds, as they are called. See GOURD.

MELONS, *petrified*, a name given by the people who have written books of travels, &c. to certain stones found on mount Carmel. The monks who inhabit that mountain at this time, and who pretend to be the followers of Elias the prophet, tell a legendary story about these stones, which has given occasion to the name. They say, that when Elias lived on that mount, a certain gardener passing by his cave with *melons*, the prophet asked one of them; but the fellow replying, that they were not *melons*, but stones that he carried, the prophet miraculously fulfilled the saying, and converted them into stones. Travellers who are fond of these stories were usually glad to pick up one of these sacred stones as they went on; and the monks have been careful enough to gather all they could find for the better opportunity of obliging their visiters; so that though they were once very common, they are now only to be had by the favour of these people.

Breynius is the only author who has given a good account of them; he says, that they are spheric or spheroidal stones, of various sizes, from that of a hen's egg to that of the largest *melon*, or even more than that. They are generally found bedded in a very hard sand-stone, of a grey-ish or ash-colour; but they come out whole on breaking the stone, and are of a smooth surface; a grey-ish colour, or sometimes a brownish ferruginous hue. When they are broken, there is always a cavity found in them, sometimes regular and even, sometimes very irregular, and generally proportioned to the bigness of the stone. This cavity is lined on both sides with minute crystals, which are very bright and pellucid, and have their points standing toward the centre of the cavity. The substance of the *stone* itself approaches to the nature of marble, of a yellowish colour, and capable of a good polish; when wrought looking very like the Florentine marble. This is a cruft of about half an inch or an inch in thickness, according to the bigness of the stone, and sometimes this is covered with a paler-coloured cruft, of the thickness of a straw, which in some degree resembles the bark or rind of the fruit. These stones are truly a sort of concave natural nodules, of the nature of our hollow flints. They have had no fruit for their matrix, nor have ever had any of the ribs and furrows which the *melon* has, nor any mark of the stalk; and within they have neither the natural divisions of the *melon*, nor any thing resembling the seeds. It is not only the want of many parts absolutely essential to the fruit supposed to be petrified, which shews that opinion to be erroneous; but the course of nature, in petrifactions in general, argues also greatly against it.

The things we meet with, in this state, are all of them such as are naturally hard, dry, and permanent, and none of the tender and succulent bodies, such as the *melon*, and the like fleshy fruits, which must necessarily rot in the water that conveys the stony matter, before it could at all enter their pores. And the stones are certainly analogous to those concave nodules of a ferruginous colour, in the cavities of which amethysts are produced; and to that genus of stones which Woodward calls concave crystalline balls, common in many parts of the world.

The fallacy of an extravagant opinion in regard to fossils of any particular form, is not peculiar to these stones, as witness the fossil shells petrified and found [illegible] which from their flat and roundish shape, are [illegible] the lentiles, which the children of Israel eat [illegible] ing the pyramids: the *cornua Ammonis*, which [illegible] mains of a sea-shell, and yet is supposed to [illegible] serpent; the *autumi miracules*, which are the [illegible] of shell-fish, but are generally supposed by the vulgar, about

about the places where they are found, to be medals and coins petrified with lying in the earth, and many the like follies. Breyn. de Melon. Petr. Mont. Caran.

MELON-*thistle*. See *Melon* THISTLE.

MELON, *water*, or CITRUL, *anguria*, in *Botany*. Its characters are these: it has male and female flowers on the same plant; which are both of them of the open bell-shaped kind, of one leaf; the male flowers have three short stamina joined together; the female flowers rest upon an oval germen, which becomes an oblong fleshy fruit; having five cells filled with compressed seeds, rounded at the extremities. There is one species which is cultivated in warm countries, and is much esteemed for its cooling fruit.

Linnæus has joined the citrul to the GOURD; and the *anguria* to the CUCUMBER, and made a distinct genus of the *anguria*, in the class of *monœcia diandria*, having male and female flowers, the empalement of each being divided into five segments, and the flower bearing five petals; the fruit is a double-celled polyspermous apple. Of this genus he reckons three species.

There is little difference in cultivation required between this and the musk *melon*.

The seeds have the same medicinal qualities ascribed to them, as those of the gourd.

MELONGENA, in *Botany*, a species of the solanum or NIGHT-SHADE. See MAD-*Apple*.

MELOPŒIA, a name given by the ancients to that part of MUSIC, which answers to the HARMONICA.

MELOPEPO, *calabash*, in *Botany*, a species of the *cucurbita* or GOURD. Some make this a distinct genus of plants, of a middle nature, as their name expresses, between the melon and the pompion.

The species of this genus, enumerated by Mr. Tournefort, are fourteen.

MELOTIS, a word used by the chirurgical writers to express a small probe, properly one intended to be used only to the ear.

MELOTHRIA, *small creeping cucumber*, in *Botany*, a genus of the *triandria monogynia* class: its characters are, that the empalement is of one leaf, bell-shaped, and cut slightly at the brim into five parts; the flower is wheel-shaped, having a tube of the length of the empalement; in the centre of the flower is situated the pointal, supporting a cylindrical style, accompanied by three conical stamina, inserted in the tube of the flower, and extended to the same length; the pointal becomes an oval small berry, having three divisions, in which are lodged small flat seeds. There is only one species.

MELPOMENE, the name of one of the nine MUSES; who is represented with a mask to denote her presiding over the stage; and distinguished from THALIA, the comic Muse, by greater dignity in her look, stature, and dress. *Melpomene* was supposed to preside over all melancholy subjects, as well as tragedy. See Horace, lib. i. od. 24. v. 4. lib. iii. od. 30. v. ult.

MELT. See MILT.

MELTING-*cone*, in *Assaying*, is a small vessel made of copper or brass, of a conic figure, and of a nicely polished surface within. Its use is to receive melted metals, and serve for their precipitation, which is effected, when two bodies melted together, and yet not mixing perfectly with one another in the fusion, separate in the cooling into two strata, on account of their different specific gravity. This precipitation might be made in the same vessel in which the fusion is performed; but then the melting-pot or crucible must be broken every time to get it out, whereas the conic shape, and polished surface of this vessel, makes it easily got out without violence. The shape of this vessel is also of another use in the operation; for by means of it, the heavy matter subsiding to a point, is formed into a perfect and separate regulus, even where the whole quantity, as is very frequently the case, has been but very small.

When the quantity of the melted matter is great, it is common to use, instead of this cone, a large brass or iron mortar, or any other conveniently shaped brass or iron vessel. It is necessary, when the cone is of brass, to be cautious that it be not made too hot; for the brittleness of that metal, when hot, makes it easily break on the striking with any force on that occasion, to make the melted mass fall out.

These, and all other moulds for the receiving melted metals, must always be well heated before the mass is poured into them, lest they should have contracted a moisture from the air, or have been wetted by accident; in which case the melted metal will be thrown out of them with great violence and danger. They ought also to be smeared over with tallow on their inside, that the regulus may be the more easily taken out of them, and the surface of the mould not corroded by the melted mass poured in.

If a very large quantity of a metal is, however, to be received into them, and especially if any thing sulphureous have place among it, this caution of tallowing the moulds does not prove sufficient; for the large quantity of the mass makes it continue hot so long, that this becomes but a slight defence to the surface of the mould. In this case the assayer has recourse to a lute, reduced to a thin pap with water, which being applied in form of a very thin crust, all over the inside of the cone, or mould, soon dries up indeed, but always preserves the sides of the vessel from the corrosion of the mass. And this caution is found necessary, even when pure copper is melted alone, without any mixture of sulphur. See *Tab.* II. *of Chemistry*, N° 25.

MELTING *fire*. See FIRE.

MELTING, *surveyor of*. See SURVEYOR.

MEMECYLON, in *Botany*, a name by which some authors have called the *arbutus*, or strawberry-tree, a shrub preserved in the gardens of the curious. Ger. Emac. Ind. 2.

MEMECYLON, in the Linnæan system of *Botany*, is a distinct genus of the *octandria monogynia* class: its characters are, that the empalement has an entire margin, and the flower a single petal; the fruit is a berry crowned with a cylindric empalement. There is only one species.

MEMAICULA, in the *Materia Medica of the Ancients*, a name given to a fruit, ordered in some compositions as an astringent and a cooler. When the Greek writers use this word, their Latin translators usually render it by the word *unedo*. Pliny says, that *unedo* is the name of the fruit of the *arbutus*, or strawberry-tree; but we find the earliest Latin writers do not countenance this. Varro calls the fruit of the *arbutus* by the name *arbutus*, as he does the fruit of the mulberry or morus, by the name *morus*. And it seems to have been contrary to the general custom of the times to have imposed a name upon a fruit, different from that of the tree which bore it. Some of the commentators say that the *memaicula*, or *unedo* was no other than the common wood-strawberry; and Ægineta in one place says, that the fruit of the *camarus*, that is, of the *arbutus*, was called *memaicula*; but in another place he gives a much better explication of the word, saying, that some of the Greeks used it as the name of the fruit of the CORNUS *mas*, or male cornel-tree.

MEMBERS, in *Anatomy*, the exterior parts, arising from the trunk or body of an animal, like the boughs from the trunk of a tree.

In which sense, *members*, *membra*, amount to much the same with *limbs*, *artus*: though some make a difference between the two; restraining *members* more immediately to the fleshy parts which cover the limbs, and artus to the bones and nerves. Physicians divide the body into three regions or venters; the head, the breast, and the lower ventricle; and the extremities, which are the *members*.

MEMBER, in *Architecture*, denotes any part of a building; as a frieze, cornice, or the like.

MEMBER is sometimes also used for MOULDING.

MEMBER, in *Grammar*, is applied to the parts of a period, or sentence.

MEMBER is also used to denote some particular order or rank in a state or government: thus we say, *member* of a corporation, *member* of parliament, *member* of the council, &c.

MEMBERED, or MEMBRED, in *Heraldry*, is when the beak, or legs, or feet of an eagle, griffin, or other bird, are of a different colour from the rest of the body.

MEMBRANA, in *Anatomy*. See MEMBRANE.

MEMBRANA *carnosa*. See PANNICULUS, &c.

MEMBRANA *nictitans*. See NICTITATING.

MEMBRANA *tympani*. See TYMPANUM and FORAMEN.

MEMBRANA *urinaria*. See ALLANTOIS.

MEMBRANE, MEMBRANA, in *Anatomy*, a similar part of an animal body; being a thin, white, flexible, expanded skin, formed of several sorts of fibres interwoven together, and serving to cover, or wrap up, certain parts of the body.

The *membranes* of the body are various; and variously denominated. Such are the periosteum pleura, pericardium, peritonæum, &c. which see under their proper articles. Such also are the *adiposa*, *carnosa*, and *nictitating*.

Those *membranes* which serve as integuments or covers of vessels, are called *coats*, or *tunics*; and those which cover the brain, are, by a peculiar name, called *meninges*. The fibres of *membranes* give them an elasticity, whereby they can contract, and closely grasp the parts they contain; and their nervous fibres give them also an exquisite sense, which is the cause of their contractions. They can therefore scarcely suffer the sharpness of medicines, and they are difficultly united, when wounded. In their texture, there is a number of small glands, which separate

an humour, fit for moiſtening the parts they contain. By reaſon of the fineneſs and tranſparency of the *membranes*, the ramifications of the blood-veſſels are more apparently ſeen in them, than in any other part of the body: here the innumerable diviſions, windings and turnings, ſerpentine progreſſions, and frequent inoculations, not only of veins and arteries together, but alſo of veins with veins, and arteries with arteries, make a moſt agreeable embroidery, and delicate net-work, covering the whole *membrane*.

The uſe of the *membranes* is to cover and wrap up the parts, and ſtrengthen them; to ſave them from external injuries; to preſerve the natural heat; to join one part to another; to ſuſtain ſmall veſſels, and the nerves which run through their duplicatures; to ſtop the returning of the humours in their veſſels, as the valves ſtop the returning of the blood in the veins and heart; of the chyle in the thoracic duct; and of the lympha in the lymphatic veſſels.

Anatomiſts generally aſſert, that there is a *membrana communis muſculorum*, or *membrane* common to all the muſcles; being led into that miſtake by the aponeuroſis of ſeveral; whereas, upon ſtricter obſervation, there is no ſuch thing to be found.

The *membrana propria muſculorum* is that which immediately covers all and every one of the fibres of a muſcle, and is cloſely tacked to them. There is another common *membrane*, called *membrana communis faſciculorum*; which is a thin *membrane*, accompanying almoſt all the veſſels of the body. See MUSCULAR *Membrane*.

All theſe *membranes* receive veins, arteries, and nerves, from the parts which are neareſt to them.

Mr. Leewenhoeck has been at the pains of examining with great nicety, the fine *membranes* which incloſe the faſciculi or ſmall bundles of fibres of which a muſcle is compoſed. Between theſe faſciculi the *membrane* is of a conſiderable thickneſs, but it divides itſelf every way into very fine and ſmall branches. This *membrane* is evidently compoſed of a number of ſmall veſſels, and theſe may be diſtinguiſhed not only in its thick parts, but even where it is ever ſo ſmall and fine, ſo far as the microſcope can trace it; but this is not ſo far as might be wiſhed; for the *membrane* ſtill divides itſelf in its progreſs into more and more ramifications, and where it envelopes only a ſingle fibre, is not to be diſtinguiſhed with any degree of preciſion, even with the beſt microſcopes. The ſmall veſſels extended through this *membrane*, are doubtleſs intended to convey nouriſhment to it; but it is very certain that the globules of blood can never paſs into ſuch ſmall canals. Phil. Tranſ. N° 322. p. 140.

MEMBRANE, *adipoſe*, in *Anatomy*, denotes a membrane inveſting the body, immediately under the cutis; ſuppoſed to be the baſis of the fat, which is lodged in the ſpaces between its fibres, and in peculiar cells formed herein.

Anatomiſts are divided as to the reality of this *membrane*; moſt of the later writers taking it to be no other than the exterior *membrane* of the membrana carnoſa, or muſculorum communis.

It was the opinion of Boerhaave, that the ſeat of the *lues venerea*, or pox, was in the *membrana adipoſa*. There are many ſeeming difficulties which have prevented the generality of the learned world from giving into this; but there have been ſeveral particular caſes, the ſymptoms of which ſeem to prove it really to be ſo.

Of theſe Dr. Huxham gives one, which alone may ſeem ſufficient to prove the reality of it. This is of a gentleman of about twenty-ſeven years of age, and of a hot bilious conſtitution, who ſome years before his death had got a gonorrhœa, and before that was cured, a ſecond, and after that a third; and after all theſe, had frequent impure converſations with the negro women in the Weſt Indies, who probably had that worſt ſpecies of pox, the yaws. He had, after this, a terrible itching under his ſkin, and a very ſtinking breath, and ſpit corrupt matter, but had no running ulcer, bubo, node, or other of the common ſymptoms of a confirmed pox; but after repeating his raſh conduct with ſome women in England, he had a gonorrhœa, of which he could not get cured, for a bubo appeared in the groin, and verrucoſe ſwellings about the anus.

One of theſe breaking diſcharged a great quantity of matter, and after that others appeared, the bubo would not ſuppurate, and ſcabs appeared in ſeveral parts of his body. He was fumigated with cinnabar, and a ſalivation propoſed; but after taking at three ſive drams of calomel, he had not the leaſt ſoreneſs of the gums, though that medicine had not purged nor vomited him. At length turbith vomits, and large doſes of mercurials, to which he had been much accuſtomed before, brought on a ſoreneſs of the mouth; but the ſpitting was tough, and did not amount to a pint a day. During this courſe the ſcaly eruptions increaſed, and he was at length covered with them all over, and his limbs ſwelled, and even burſt in many places, the fiſſures diſcharging a ſtinking ichorous matter.

Hot baths and mercurial ointments were uſed on this, but the diſeaſe ſtill increaſed under theſe means; the ſcales grew ſo ſtiff, that he could not move his limbs, and ulcers appeared in many parts, particularly a large tumor on each breaſt, which diſcharged vaſt quantities of an oily ſtinking matter. It was obſervable, that where theſe tumors and ulcers appeared, they only ran under the ſkin, being entirely ſeated in and feeding on the *membrana adipoſa*, ſo that the muſcles and tendons underneath appeared as fair and florid as in the moſt healthy conſtitution.

It was now plain, that mercury could do nothing toward a cure in any form, and the old method of ſweating was attempted with warm baths, to looſen the ſcales; by this means they came off apace in the manner of thoſe of the confluent ſmall-pox, but larger, ſome of theſe being four or five inches over. In a week's time, the coat of mail was cleared off, and his breath became ſweet; but the ulcers ſtill diſcharging great quantities, and notwithſtanding all that had been done, two large ſhankers appeared on the glans, and a bubo in each groin: he was alſo ſeized with a cough, and ſpit purulent and bloody matter. It was evident that the whole *membrana adipoſa* had been conſumed from the external part of the body, and the diſeaſe now began to ſeize on that part of it which inveſted the more vital parts; but nature could ſupport it no longer, and he died in the moſt extreme degree of a pocky conſumption. It is obſervable that not one bone in the whole body appeared to be touched, though he died with more than forty ulcers upon him. Phil. Tranſ. N° 460. p. 671.

MEMBRANES *of the eye*. See EYE.

MEMBRANE, *nictitating*. See NICTITATING.

MEMBRANACEOUS *leaf*. See LEAF.

MEMBRANOSA *armilla*. See ARMILLA.

MEMBRANOSUS, or *muſculus faſciæ latæ*, in *Anatomy*, is a ſmall and pretty long muſcle, ſituated a little obliquely upward and downward on the fore part of the hip. It is fixed above to the outſide of the anterior ſuperior ſpine of the os ilium, between the inſertions of the glutæus medius, and ſartorius. From thence its fleſhy fibres run down a little obliquely backward, forming a very flat body, four fingers breadth in length, and two in breadth, which lies between two lamine of the FASCIA *lata*, and is inſerted therein by ſhort tendinous fibres. Winſlow. See *Tab. Anat. Muſcul. fig.* 2. *n.* 34. *fig.* 1. *n.* 48. *fig.* 6. *n.* 34.

MEMBRAS, in *Ichthyology*, a name given by Rondeletius, Aldrovand, and other writers, to the HERRING.

MEMBRED. See MENBRED.

MEME. *Queſt of* MEME. See QUE.

MEMIREN, in the *Materia Medica*, the name by which Scraphion and ſome other authors have called the pilewort, or ſmall celandine.

MEMITHA, in the *Materia Medica of the Ancients*, the name of a plant which ſome have ſuppoſed to be our cerinthe, but others the glaucium, or yellow-horned poppy.

MEMOIRS, or MEMORIALS, a term now much in uſe for hiſtories compoſed by perſons who had ſome ſhare or concern in the tranſactions they relate, or who were eye-witneſſes of them; anſwering to what the Latins called *commentarii*.

The French are great dealers in this way of writing, and have an infinite number of books of *memoirs*, containing, for the generality, the lives, actions, intrigues, amours, &c. of the writers.

MEMOIRS is alſo uſed for a journal of the acts and proceedings of a ſociety; or a collection of the matters debated, tranſacted, &c. therein. Such are the *Memoirs* of the Royal Academy of Sciences, &c.

MEMORY, *ſubſt.* a power or faculty of the mind, which receives, retains, and exhibits again, as occaſion requires, all ſorts of ideas preſented to the underſtanding.

Of all the faculties, there is none harder to account for, or that has perplexed philoſophers more, than the *memory*. Some will have it a mere organ, as the eye, ear, &c. Dr. Hook, in an *Eſſay towards a mechanical Account of Memory*, makes it to conſiſt in a ſtock of ideas or images, formed occaſionally by the mind, out of the fine parts of the brain, and diſpoſed or laid by in order.

Deſcartes, and his followers, maintain, that the animal ſpirits, exciting a motion in the moſt delicate fibres of the brain, leave a kind of traces or footſteps, which they call *reverberance*. Hence it happens, that by paſſing ſeveral times over the ſame things, the ſpirits, becoming accuſtomed to the ſame paſſages, leave them open, ſo as to make their way without any effort or labour; and in this conſiſts the eaſe wherewith we recollect ſuch things. Thus when it is found to ſharpen the *memory*, it regard the ſpirits

spirits of the wine put the animal spirits in motion, and agitate the fibres of the brain more briskly.

Father Malebranche expresses his notion of *memory* thus: "It being granted, that all our different perceptions are "owing to changes happening in the fibres of the prin- "cipal part of the brain, wherein the soul more imme- "diately resides, the nature of the *memory* is obvious: "for as the leaves of a tree, that have been folded for "some time in a certain manner, preserve a facility or "disposition to be folded again in the same manner; so "the fibres of the brain, having once received certain "impressions by the courses of the animal spirits, and "by the action of objects, preserve, for some time, a "facility to receive the same disposition. Now it is in "this facility that *memory* consists; for we think the same "things, when the brain receives the same disposi- "tions.

"Further, as the animal spirits act sometimes more briskly, and sometimes more languidly, on the sub- "stance of the brain; and as sensible objects make much "deeper, and more lasting impressions, than the imagi- "nation alone; it is easy, on this scheme, to conceive "why we do not remember all things alike: why a "thing, for instance, seen twice, is represented more "vividly to the mind, than another seen but once: and "why things that have been seen, are usually remem- "bered more distinctly, than those that have been only "imagined, &c.

"Old men are defective in *memory*, and cannot learn any "thing without much difficulty, because they want ani- "mal spirits to make new traces, and because the fibres "of the brain are become too hard to receive, or too "moist to retain, such impressions. For the same rea- "son, those who learn with the greatest ease, forget "the soonest: in regard when the fibres are soft and "flexible, objects make a slight impression, which the "continual course of animal spirits easily wears off. On "the contrary, the fibres of those who learn slowly, "being less flexible, and less subject to be broken, the "traces are more deeply engraven, and last the longer. "From all which observations it follows, that the *memory* "is absolutely dependent on the body; being impaired "or strengthened, according to the changes that befal "the body; a fall, the transports of a fever, &c. being "frequently found to erase or blot out all the traces, to "bear away all the ideas, and to cause an universal for- "getfulness."

The chief difficulty that clogs this doctrine of *memory* is, to conceive how such an infinite number of things, as the head is stored with, should be ranged in so much order in the *memory*, as that the one should not efface the other; and how, in such a prodigious assemblage of traces im- pressed on the brain, the animal spirits should awake pre- cisely those which the mind has occasion for.

Memory, according to Mr. Locke, is, as it were, the store- house of our ideas. For the narrow mind of man not being capable of having many ideas under view and con- sideration at once, it was necessary to have a repository, in which to lay up those ideas which it may afterwards have use of. But our ideas being nothing but actual per- ceptions in the mind, which cease to be any thing when there is no perception of them; this laying up of our ideas in the repository of the *memory*, signifies no more than this; that the mind has a power, in many cases, to revive perceptions it has once had, with this additional perception annexed to them, that it has had them before. And it is by the assistance of this faculty, that we are said to have all those ideas in our understandings, which we can bring to sight, and make the objects of our thoughts, without the help of those sensible qualities which first imprinted them there.

Attention and repetition help much to the fixing ideas in our *memories*: but those which make the deepest and most lasting impressions, are those which are accompanied with pleasure and pain. Ideas but once taken in and never again repeated, are soon lost; as those of colours in such as lost their sight when very young.

The *memory* of some men is tenacious even to a miracle; but yet there seems to be a constant decay of all our ideas, even of those which are struck deepest; and in minds the most retentive; so that if they be not sometimes re- newed, the print wears out, and at last there remains nothing to be seen.

Those ideas that are often refreshed by a frequent return of the objects or actions that produce them, fix them- selves best in the *memory*, and remain longest there: such are the original qualities of bodies, viz. solidity, extension, figure, motion, &c. and those that almost constantly affect us, as heat and cold.

In *memory*, the mind is oftentimes more than barely passive; for it often sets itself on work to search some hidden ideas; sometimes they start of their own accord; and sometimes tempestuous passions tumble them out of their cells. This faculty other animals seem to have to a great degree, as well as men, as appears by birds learn- ing of tunes, and their endeavours to hit the notes right. For it seems impossible that they should endeavour to conform their voices (as it is plain they do) to notes where- of they have no idea. Essay concerning Hum. Und. book ii. chap. 10.

Dr. Hartley, agreeably to his mechanical theory of the human mind, defines *memory* to be that faculty, by which traces of sensations and ideas recur, or are recalled, in the same order and proportion, accurately or nearly, as they were once presented: and he observes, that *memory* depends entirely or chiefly on the state of the brain, which is peculiarly conformable to his notion of VIBRATIONS. The rudiments of *memory*, he says, are laid in the per- petual recurrency of the same impressions, and clusters of impressions: and thus he endeavours to account for the peculiar imperfection of the *memory* in children and aged persons, as well as for other facts pertaining to the exer- cise of this faculty. Obs. on Man, vol. i. p. 374, &c.

For the difference between *memory* and imagination, see IMAGINATION.

Seneca says of himself, that, by the mere effort of his na- tural *memory*, he was able to repeat two thousand words upon once hearing them, each in its order; though they had no dependence or connexion on each other. After which he mentions a friend of his, Portius Latro, who retained in his *memory* all the declamations he had ever spoken, and never found his *memory* fail him, even in a single word. He also mentions Cyneas, ambassador to the Romans from king Pyrrhus, who, in one day, had so well learnt the names of his spectators, that the next he saluted the whole senate, and all the populace assem- bled, each by his name. Pliny says, that Cyrus knew every soldier in his army by name; and L. Scipio, all the people of Rome. Charmipas, or rather Carneades, when required, it is said, would repeat any volume found in the libraries as readily as if he were reading. Dr. Wallis tells us, that without the assistance of pen and ink, or any thing equivalent, he was able in the dark, by mere force of *memory*, to perform arithmetical operations, as multiplication, division, extraction of roots, &c. to forty places. Particularly, that, in February 1671-2, at the request of a foreigner (by night, in bed) he proposed to himself a number of fifty-three places, and found its square root to twenty-seven places; and, without ever writing down the number, dictated it from his *memory*, at his next visit, twenty days afterwards.

The perfection of *memory* consists in two things; readily to admit the impressions or images of things; and to preserve them from oblivion, that the understanding may have recourse to them, and employ them for such pur- poses, as reason shall direct. In order to assist and im- prove this faculty, every kind of intemperance and excess must be carefully avoided; and when we would commit any thing to *memory*, our first concern should be to un- derstand it thoroughly; writing down any thing is like- wise a great advantage towards remembering it; care should likewise be taken not to overburden the *memory*: such seasons should be made choice of as are most proper for the exercise of this faculty, such are the evening and morning; and the most effectual way of gaining a good *memory*, is its constant and moderate exercise. Ward's Or. vol. ii. sect. 51.

MEMORY, *local*, or *artificial*, is an art or invention, by means whereof the *memory* is supposed to be aided, strengthened, and enlarged.

This art seems to consist in nothing else but a certain method of coupling or associating the ideas of things to be remembered, with the ideas of other things, already disposed orderly in the mind, or that are before the eyes. It is of an old standing, having been practised by many of the ancient orators; some whereof are said to have made use of paintings, images, and emblems, on this occasion; though others contented themselves with the parts, members, ornaments, furniture, and other cir- cumstances of the place where they were to speak. Muretus tells us, that a young man of Corsica pretend- ing to do wonders this way, Muretus put him to the trial: and upon dictating to him two or three thousand words, some Greek, some Latin, some Barbarous; all without any relation to each other, and the greatest part without any meaning at all; the artist immediately, and without any hesitation, or the least stumbling or displacing, re- peated them all, from first to last, in the same order wherein they had been dictated; and this done, begin- ning where he ended, he repeated them all backwards, from last to first. Adding, that this was but a slight essay of his *memory*; and that he would undertake to repeat thirty-six thousand words in the same manner.

The truth is, this art seems better calculated for retain-

ing

ing things without any coherence or dependence on one another, as mere words or sounds, &c. than for things where reason or judgment are any way required.

Raim. Lully took so much pains with it, that it now goes by his name, being called *Lully's art*.

Many have been the attempts, in all ages, to assist the *memory*. Some have had recourse to medicine, such as Horstius, Marsilius, Ficinus, Johnllon, and others. That good health, a good digestion, and a mind free from care, are helps in this respect, is an old observation. That attention, application, frequent recapitulation, are necessary, is known to every one. But whether, besides natural health and parts, and the exercise of our faculties, art may not give a farther assistance to *memory*, has been a question. Simonides is said to have been the first who found out the art of *memory*. His method was by a choice of *places* and *images*, as a repository of ideas; such, for instance, as a large house divided into several apartments, rooms, closets, &c. All these, and their order, were to be rendered extremely familiar to the imagination and *memory*. Then, whatever was to be remembered, was by some symbolical representation or another, as an anchor for navigation, to be connected with some part of the house, or other artificial repository, in a regular manner. Cicero, and Quintilian give us some account of this method, and speak of it with respect. Several moderns have attempted improvements of artificial *memory*. There was a collection of various treatises of this kind published at Leipzig; this and Bruuius's Simonides Redivivus, are commended by Morhof. Paschius gives us some account also of several authors who have treated of this art. It is certainly of use in history and chronology. The chief artifice, in this respect, is to form an artificial word, the letters of which shall signify numbers. Hence a date or *æra* may more easily be recapitulated and remembered than without such a contrivance. This invention is mentioned as a secret known to few, by Paschius. It has been prosecuted lately in England, by Dr. Grey.

The method is this: to remember any thing in history, chronology, geography, &c. a word is formed, the beginning whereof being the first syllable or syllables of the thing to be remembered, does, by frequent repetition, of course draw after it the latter parts, which is so contrived as to give the answer. Thus, in history, the deluge happened in the year before Christ 2348. This may be signified by the word *Del ecet*; Del standing for deluge, and *ecet* for 2348. How these words come to signify these things, or contribute to the remembering them, is now to be shewn.

The first thing to be done, is to learn exactly the following series of vowels and consonants, which are to represent the numerical figures, so as to be able at pleasure to form a technical word, which shall stand for any number, or to resolve a word already formed into the number it stands for.

a	*e*	*i*	*o*	*u*	*ai*	*ei*	*au*	*y*
1	2	3	4	5	6	7	8	9	0
b	*d*	*t*	*f*	*l*	*i*	*p*	*k*	*n*	*s*

Here *a* and *b* stand for 1, *e* and *d* for 2, *i* and *t* for 3, and so on. These letters are assigned arbitrarily to the respective figures, and may very easily be remembered. The first five vowels in order naturally represent 1, 2, 3, 4, 5. The diphthong *ai*, being composed of *a*, 1, and *u*, 5, stands for 6; *ei* for 7, being composed of *e*, 2 and *i*, 3; *au* for 8, being composed of *o*, 4 and *u*, 5: The diphthong *ei* will easily be remembered for 8, being the initials of the word. In like manner for the consonants, where the initials could conveniently be remined, they are made use of to signify the number, as *f* for 4, *s* for 6, and *n* for 9. The rest were assigned without any particular reason, unless that possibly *p* may be more easily remembered for 7, or *septem*, *k* for 8, or *octo*, *d* for 2, or *duo*; *b* for 1, as being the first consonant, and *l* for 5, being the Roman letter for 50, than any others that could have been put in their places. Mem. Techn. p. 2, 3. It is farther to be observed, that *s* and *y* being made use of to represent the cypher, where many cyphers meet together, as 1000, 1000000, &c. instead of a repetition of *a* or *y*, *s*, *y*, &c. let *s* stand for 100, *sh* for a thousand, and *m* for a million. Thus *ag* will be 100, *if* 300; *sug* 900, &c. *with* 1000, *um* 1000000, *fourm* 90000000, &c. Ib. p. 5. Fractions may be set down in the following manner: let *r* signify the line separating the numerator and denominator, the first coming *before*, the other *after* it; as *ire* ⅓, *urp* ¼, *pourgr* ⅑, &c. When the numerator is 1 or unit, it need not be expressed, but begin the fraction with *r*; as *re* ½, *ri* ⅓, *ro* ¼, &c. So in decimals, *roy* ·12, *roth* ·108. Ibid.

This is the principal part of the method, which consists in expressing numbers by artificial words. The application to history and chronology is also performed by artificial words. The art herein consists in making such a change in the ending of the name of a place, person, planet, coin, &c. without altering the beginning of it, as shall readily suggest the thing sought, at the same time that the beginning of the word, being preserved, shall be a leading or prompting syllable to the ending of it so changed. Thus in order to remember the years in which Cyrus, Alexander, and Julius Cæsar, founded their respective monarchies, the following words may be formed; for Cyrus, *Ceruis*; for Alexander, *Alexita*; for Julius Cæsar, *Julice*. *Uis* signifies, according to the powers assigned to the letters before mentioned, 536; *ice* is 331, and *as* is 46. Hence it will be easy to remember, that the empire of Cyrus was founded 536 years before Christ, that of Alexander 331, and that of Julius Cæsar, 46. Mem. Techn. Introd. p. viii. and ix.

For the farther application of this method, we refer to the ingenious author of the last cited book. We shall only add, that *technical verses* contribute much to the assistance of the *memory*, both as they generally contain a great deal in a little compass, and also because, being once learned, they are seldom or never forgot. The author before quoted has given us several specimens of such verses in history, chronology, geography, and astronomy, as also the Jewish, Grecian and Roman coins, weights and measures, &c. He advises his reader to form the words and verses for his own use himself; as he perhaps will better remember them than those formed by the author. Lib. citat. Introduct. p. xi.

As to Simonides' method, Quintilian says he will not deny it to be of some use; for instance, in repeating a multitude of words in the order they occur, and in things of this nature: but he thinks it of less use in getting by heart a continued oration, and in this respect rather an incumbrance. He himself advises, if the speech to be remembered be long, to get it by heart in parts, and those not very small. The partition ought chiefly to be made according to the different topics. He thinks it best to get things by heart tacitly, and if, the better to fix the attention, the words be pronounced, yet it should be in a low voice. Apt divisions help the *memory* greatly. But after all, the great art of *memory* is exercise; to get many things by heart, and daily, if possible. Nothing increases more by use, or suffers more by neglect, than the *memory*. At whatever age a man aims at the improvement of this faculty, he should patiently submit to the uneasy labour of repeating what he has read or written. Here, as in other cases, where habits are to be acquired, exercise should be increased by degrees. Quint. Inst. Orat. lib. xi. cap. 2. p. 989.

Lord Bacon enumerates several helps to *memory*, as order, artificial place, verse, whatever brings an intellectual thing to strike the senses, and those things which make an impression by means of a strong passion, as fear, surprize, &c. Those things also sink deepest, and dwell longest in the *memory*, which are impressed upon a clear mind unprejudiced either before or after the impression, as the things we learn in childhood, or think of just before going to sleep; as likewise the first times things are taken notice of.

A multitude of circumstances also, or, as it were, handles or holds to be taken, help the *memory*; as the making many breaks in writing, reading or repeating aloud: but as to this last, see Quintilian's opinion before mentioned. Those things which are expected, and raise the attention, stick better than such as pass slightly over the mind; who sees if a man reads any writing twenty times over, he will not remember it so well, as if he read it but ten times with trying between whiles to repeat it, and consulting the copy where his *memory* failed. Bacon's Works abr. vol. ii. p. 275. See also vol. i. p. 128, 136. vol. iii. p. 176. and the article MNEMONIC *Tables*.

MEMORY, *weakness of*, in many cases, is to be considered as a disease, and is looked on in that light by the medical writers, who have prescribed various remedies for it. The principal causes of this debility, are a too frequent and constrained use, or rather abuse of it, in the getting by rote numbers of words and syllables, particularly in the learning different languages; a paralytic affection in the head; violent external injuries in the same part; violent pains in the head attended with delirium's, or attending a PHRENITIS. And to these are to be added drunkenness, and an abuse of venery.

Prognostics. All debilities of *memory* are cured with great difficulty by medicines alone; and indeed this complaint is seldom removed, unless the whole frame of mind and course of life be altered; all passions avoided, and excess of every kind left off. But of all other kinds, that debility of *memory* which proceeds from a paralytic disorder of the head, particularly when that disorder affects the tongue, is found to be the most obstinate and difficult of

cure. Much sleep, or excessive waking, are equally hurtful to the *memory*, and frequently bring on an almost total loss of it.

Method of treatment. All such medicines as are of an agreeable taste or odour, are generally supposed to be of service in strengthening the *memory*; and *lignum aloes*, ambergris, and some other of the fragrant drugs, have been known to do great good. The aromatic, volatile, and spirituous medicines, also all help in this case, if taken in small doses, and continued for a long time together. The analeptics and nervine medicines are also greatly recommended, but they are seldom found of use; for among people afflicted with a debility of *memory*, many are those of robust constitutions and strong appetites, who eat already more than nature requires, and have therefore very little use for analeptics or nutritive things. Bleeding in small quantities frequently repeated, in cases where there is no contrary indication, frequently proves of great service in this case; but the *primæ viæ* are first to be cleansed before such a course is entered upon. Many greatly recommend bags of aromatics to the head, and to be constantly worn in caps; but it is much to be feared these can have but very little effect. Junck. Consp. Med. p. 682.

MEMPHITES, or *lapis* MEMPHITICUS, a sort of stone mentioned by Dioscorides, Pliny, and other natural historians, supposed to be found in Egypt, not far from the city of Cairo, the ancient Memphis, whence its name.

The property it is famed for is, that being pulverized and sneezed on any part of the body to be cut off, it deadens it so, as that the patient shall perceive no pain, they say, from the operation.

MEN.—*Adelphipæus, Mens, Pars, Quæst, Sides, Twelve, Votary* MEN. See the adjectives.

MEN *allegro*, in the *Italian Musick*, is used to denote a movement not so brisk and lively as ALLEGRO.

MEN *forte*, in the *Italian Musick*, intimates that the part to which it is added ought to be played or sung not so strong or so loud as the *tutti*.

MEN *presto*, in the *Italian Musick*, signifies less quick. See PRESTO.

MENAGE, Fr. denotes a collection of animals; whence we have derived the word *menagery*.

MENAIS, in *Botany*, a genus of the *pentandria monogynia* class. Its characters are, that it has an hypocrateriform flower, a three-leaved empalement, and that the fruit is a four-celled berry, containing a single seed. There is only one species.

MENALD *deer*, a species of the common fallow-DEER, beautifully variegated.

MENANDRIANS, the most ancient branch of Gnostics; thus called from Menander their chief, said by some, without sufficient foundation, to have been a disciple of Simon Magus, and himself a reputed magician.

He taught, that no person could be saved, unless he were baptized in his name: and he conferred a peculiar sort of baptism, which would render those who received it immortal in the next world: exhibiting himself to the world, with the phrenzy of a lunatic more than the founder of a sect, as a promised saviour. For it appears by the testimonies of Irenæus, Justin, and Tertullian, that he pretended to be one of the ÆONS sent from the pleroma, or ecclesiastical regions, to succour the souls that lay groaning under bodily oppression and servitude; and to maintain them against the violence and stratagems of the demons that hold the reins of empire in this sublunary world. As this doctrine was built upon the same foundation with that of Simon Magus, the ancient writers looked upon him as the instructor of *Menander*. See SIMONIANS.

MENDÆANS, in *Ecclesiastical History*. See HEMEROBAPTISTS.

MENDICANTS, *beggars*, a term applied to several orders of religious, who live on alms, and go a-begging from door to door.

The religious society distinguished by this appellation surpassed all the rest in the purity of its manners, the extent of its fame, the number of its privileges, and the multitude of its members. Its order was first established in the 13th century, and the members of it, by the tenor of their institution, were to remain entirely destitute of all fixed revenues and possessions; though in process of time their number became a heavy tax upon the people. Innocent III. was the first of the popes who perceived the necessity of instituting such an order, and accordingly he gave such monastic societies, as made a profession of poverty, the most distinguishing marks of his protection and favour. They were also encouraged and patronized by the succeeding pontiffs, when experience had demonstrated their public and extensive usefulness. But when it became generally known, that they had such a peculiar place in the esteem and protection of the rulers of the church, their number grew to such an enormous and unwieldy multitude, and swarmed so prodigiously in all the European provinces, that they became a burthen, not only to the people, but to the church itself. The great inconveniences that arose from the excessive multiplication of the *mendicant* orders was remedied by Gregory X. in a general council, which he assembled at Lyons, in 1272. For here all the religious orders that had sprung up after the council held at Rome, in 1215, under the pontificate of Innocent III. were suppressed; and the extravagant multitude of *mendicants*, as Gregory called them, were reduced to a smaller number, and confined to the four following societies or denominations, viz. the DOMINICANS, the FRANCISCANS, the CARMELITES, and the AUGUSTINS, or hermits of St. Augustin.

As the pontiffs allowed these four *mendicant* orders the liberty of travelling wherever they thought proper, of conversing with persons of every rank, of instructing the youth and multitude wherever they went; and as these monks exhibited, in their outward appearance and manner of life more striking marks of gravity and holiness, than were observable in the other monastic societies, they arose all at once to the very summit of fame, and were regarded with the utmost esteem and veneration through all the countries of Europe. The enthusiastic attachment to these sanctimonious beggars went so far, that, as we learn from the most authentic records, several cities were divided, or cantoned out into four parts, with a view to these four orders; the first part being assigned to the Dominicans, the second to the Franciscans, the third to the Carmelites, and the fourth to the Augustinians. The people were unwilling to receive the sacraments from any other hands than those of the *mendicants*, to whose churches they crowded to perform their devotions, while living, and were extremely desirous to deposit there also their remains, after death; nor did the influence and credit of the *mendicants* end here; for we find in the history of this, and of the succeeding ages, that they were employed, not only in spiritual matters, but also in temporal and political affairs of the greatest consequence, in composing the differences of princes, concluding treaties of peace, concerting alliances, presiding in cabinet councils, governing courts, levying taxes, and other occupations, not only remote from, but absolutely inconsistent with, the monastic character and profession. However the power of the Dominicans and Franciscans greatly surpassed that of the other two orders: insomuch that these two orders were, before the Reformation, what the JESUITS have been since that happy and glorious period, the very soul of the hierarchy, the engines of the state, the secret springs of all the motions of the one and the other, and the authors and directors of every great and important event, both in the religious and political world. By very quick progression their pride and confidence arrived at such a pitch, that they had the presumption to declare publicly, that they had a divine impulse and commission to illustrate and maintain the religion of Jesus; they treated with the utmost insolence and contempt all the different orders of the priesthood; they affirmed, without a blush, that the true method of obtaining salvation was revealed to them alone; proclaimed, with ostentation, the superior efficacy and virtue of their indulgences; and vaunted, beyond measure, their interest at the court of heaven, and their familiar connections with the Supreme Being, the Virgin Mary, and the saints in glory. By these impious wiles, they so deluded and captivated the miserable and blinded multitude, that they would not entrust any other but the *mendicants* with the care of their souls. They retained their credit and influence to such a degree, towards the close of the fourteenth century, that great numbers of both sexes, some in health, others in a state of infirmity, and others at the point of death, earnestly desired to be admitted into the *mendicant* order, which they looked upon as a sure and infallible method of rendering heaven propitious. Many made it an essential part of their last wills, that their bodies, after death, should be wrapped in old ragged Dominican or Franciscan habits, and interred among the *mendicants*. For such was the barbarous superstition and wretched ignorance of this age, that people universally believed they should readily obtain mercy from Christ, at the day of judgment, if they appeared before his tribunal associated with the *mendicant* friars.

About this time, however, they fell under an universal odium; but being resolutely protected against all opposition, whether open or secret, by the popes, who regarded them as their best friends, and most effectual supports, they suffered little or nothing from the efforts of their numerous adversaries. In the fifteenth century, besides their arrogance, which was excessive, a quarrel-

some and turbulent spirit prevailed among them, and drew upon them justly the displeasure and indignation of many. By affording refuge, at this time, to the BEGUINS in their order, they became obnoxious to the bishops, and were hereby involved in difficulties and perplexities of various kinds. They lost their credit in the sixteenth century, by their rustic impudence, their ridiculous superstitions, their ignorance, cruelty, and brutish manners. They discovered the most barbarous aversion to the arts and sciences, and expressed a like abhorrence of certain eminent and learned men, who endeavoured to open the paths of science to the pursuits of the studious youth, recommended the culture of the mind, and attacked the barbarism of the age in their writings and discourse. Their general character, together with other circumstances concurred to render a reformation desirable, and to accomplish this happy event. Mosheim's Eccl. Hist. vol. iii. passim.

Among the number of *mendicants* are also ranked the Capuchins, Recollects, Minims, and others, who are branches or derivations from the former.

MENENCHYTA, in *Medicine*, certain compositions of medicinal ingredients made for injecting into the womb, in the cure of several diseases of that part.

MENIAN *column*. See COLUMN.

MENING, in *Botany*, a name given by the people of Guinea to a plant of the *ricinus* or *palma Christi* kind, which they use in medicine: they dry and powder the leaves, and then give them to be snuffed up the nostrils, to cure all sorts of swellings or stoppages in the head. Its leaves resemble those of the finch and ivy, and are hairy; whence Petiver has named it *ricinus Guineensis hederæ quinquefoliæ Virginianæ facie foliis hirsutis*. It is not known to grow any where in America. Philos. Transf. N° 232.

MENINGES, Μηνιγγες, in *Anatomy*, the coats, or membranes, wherewith the BRAIN is invested.

The Arabs call them *mothers*; whence we usually call them in Latin the PIA and DURA MATER.

There are two *meninges*, external and internal, called *meninx crassa*, and *tenuis*.

Between the two, lies another fine transparent membrane, called *arachnoides*; but the best anatomists take this for no more than the external lamina of the pia mater.

MENINGOPHYLAX, a word used by Celsus as the name of a chirurgical instrument, contrived for guarding the membranes of the brain while the bone of the cranium is rasped or cut, after the operation of the trepan.

MENIPPEAN, *satire* MENIPPEA, a kind of satire consisting of prose and verse intermixed.

It is thus called from Menippus, a Cynic philosopher, who delighted in composing satirical letters, &c. In imitation of him, Varro also wrote satires under the title of *Satiræ Menippææ*: whence this sort of composition is also denominated *Varronian satire*.

Among the moderns, there is a famous piece under this title, first published in 1594, against the chiefs of the league, called also the *Catholicon* of Spain. It is esteemed a master-piece for the time.

MENISCUS, in *Optics*, a glass or lens, concave on one side, and convex on the other; sometimes also called *lunula*. See LENS, and OPTIC *glass*.

In a *meniscus*, if the diameter of the convexity be equal to that of the concavity, a ray, falling parallel to the axis, will continue parallel thereto after refraction.

Such a *meniscus*, therefore, will neither collect nor disperse the rays; and is therefore of no use in dioptrics.

To find the focus of a *meniscus*, the rule is, as the difference of the semidiameters of the convexity and concavity is to the semidiameter of the convexity, so is the diameter of the concavity to the distance of the focus from the *meniscus*. Hence, if the semidiameter of the concavity be triple the semidiameter of the convexity, the distance of the focus from the *meniscus* will be equal to the semidiameter; and therefore the *meniscus* will be equivalent to a lens equally convex on either side.

Again, if the semidiameter of the concavity be double that of the convexity, the distance of the focus will be equal to the diameter; and therefore the *meniscus* will be equivalent to a plano-convex lens.

If the semidiameter of the concavity be quintuple that of the concavity, the *meniscus* will be equivalent to a sphere. The semidiameter, therefore, of the concavity being given, that of the concavity required to remove the focus to any given distance from the *meniscus*, is easily found.

MENISPERMUM, in *Botany*. See MOON *seed*.

MENNONITES, a sect in the United Provinces, in most respects the same with those in other places called ANABAPTISTS.

They had their rise in 1536, when *Menno Simon*, a native of Friesland, who had been a Romish priest, and a notorious profligate, resigned his rank and office in the Romish church, and publicly embraced the communion of the Anabaptists.

Menno was born at Witmarsum, a village in the neighbourhood of Bolswert, in Friesland, in the year 1505, and died, in 1561, in the duchy of Holstein, at the country seat of a certain nobleman not far from the city of Oldesloe, who, moved with compassion by a view of the perils to which *Menno* was exposed, and the snares that were daily laid for his ruin, took him, with certain of his associates, into his protection, and gave him an asylum. The writings of *Menno*, which are almost all composed in the Dutch language, were published in folio, at Amsterdam, in the year 1651. About the year 1537, *Menno* was earnestly solicited by many of the sect with which he connected himself, to assume, among them, the rank and functions of a public teacher; and as he looked upon the persons, who made this proposal, to be exempt from the fanatical phrenzy of their brethren at Munster, (though, according to other accounts, they were originally of the same stamp, only rendered somewhat wiser by their sufferings,) he yielded to their intreaties. From this period to the end of his life, he travelled from one country to another, with his wife and children, exercising his ministry, under pressures and calamities of various kinds, that succeeded each other without interruption, and constantly exposed to the danger of falling a victim to the severity of the laws. East and West Friesland, together with the province of Groningen, were first visited by this zealous apostle of the Anabaptists; from thence he directed his course into Holland, Gelderland, Brabant, and Westphalia, continued it through the German provinces that lie on the coasts of the Baltic sea, and penetrated so far as Livonia. In all these places his ministerial labours were attended with remarkable success, and added to his sect a prodigious number of followers. Hence he is deservedly considered as the common chief of almost all the anabaptists, and the parent of the sect that still subsists under that denomination. *Menno* was a man of genius, undirected by a very sound judgment; he possessed a natural and persuasive eloquence, and such a degree of learning as made him pass for an oracle in the estimation of the multitude. He appears, moreover, to have been a man of probity, of a meek and tractable spirit, gentle in his manners, pliable and obsequious in his commerce with persons of all ranks and characters, and extremely zealous in promoting practical religion and virtue, which he recommended by his example, as well as by his precepts. The plan of doctrine and discipline drawn up by *Menno* was of a much more mild and moderate nature than that of the furious and fanatical ANABAPTISTS, whose tumultuous proceedings have been recited under that article, but somewhat more severe, though more clear and consistent than the doctrine of the wiser branches of that sect, who aimed at nothing more than the restoration of the Christian church to its primitive purity. Accordingly, he condemned the plan of ecclesiastical discipline, that was founded on the prospect of a new kingdom, to be miraculously established by Jesus Christ on the ruins of civil government and the destruction of human rulers, and which had been the fatal and pestilential source of such dreadful commotions, such execrable rebellions, and such enormous crimes. He declared, publicly, his dislike of that doctrine, which pointed out the approach of a marvellous reformation in the church by the means of a new and extraordinary effusion of the Holy Spirit. He expressed his abhorrence of the licentious tenets, which several of the anabaptists had maintained, with respect to the lawfulness of polygamy and divorce; and, finally, considered as unworthy of toleration those fanatics who were of opinion that the Holy Ghost continued to descend into the minds of many chosen believers, in an extraordinary manner as he did at the first establishment of the Christian church, and that he testified this peculiar presence to several of the faithful, by miracles, predictions, dreams, and visions of various kinds. He retained, indeed, the doctrines commonly received among the Anabaptists, in relation to the baptism of infants, the millennium, or thousand years reign of Christ upon earth, the exclusion of magistrates from the Christian church, the abolition of war, and the prohibition of oaths enjoined by our Saviour, and the unity, as well as the pernicious effects, of human science. But while *Menno* retained these doctrines in a general sense, he explained and modified them in such a manner, as made them resemble the religious tenets that were universally received in the protestant churches; and this rendered them agreeable to many, and made them appear inoffensive even to numbers who had no inclination to embrace them. It however so happened, that the nature of the doctrines

considered

considered in themselves, the eloquence of *Menno*, which set them off to such advantage, and the circumstances of the times, gave a high degree of credit to the religious system of this famous teacher among the Anabaptists, so that it made a rapid progress in that sect. And thus it was in consequence of the ministry of *Menno*, that the different sorts of Anabaptists agreed together in excluding from their communion the fanatics that dishonoured it, and in renouncing all tenets that were detrimental to the authority of civil government, and, by an unexpected coalition, formed themselves into one community.

Though the *Mennonites* usually pass for a sect of Anabaptists, yet M. Herman Schyn, a *Mennonite* minister, who has published their history and apology, maintains, that they are not Anabaptists, either in principle or by origin. However, nothing can be more certain than this fact, viz. that the first *Mennonite* congregations were composed of the different sorts of Anabaptists, of those who had been always inoffensive and upright, and of those who, before their conversion by the ministry of *Menno*, had been seditious fanatics: besides it is alledged, that the *Mennonites* do actually retain, at this day, some of those opinions and doctrines, which led the seditious and turbulent Anabaptists of old to the commission of so many and such enormous crimes: such particularly is the doctrine concerning the nature of Christ's kingdom, or of the church of the New Testament, though modified in such a manner as to have lost its noxious qualities, and to be no longer pernicious in its influence.

The *Mennonites* are subdivided into several sects; whereof the two principal are the *Rhinsburgers*, or FLEMINGIANS, and the WATERLANDIANS. The opinions, says Mosheim, that are held in common by the *Mennonites* seem to be all derived from this fundamental principle, that the kingdom which Christ established upon earth is a visible church or community, into which the holy and just alone are to be admitted, and which is consequently exempt from all those institutions and rules of discipline, that have been invented by human wisdom, for the correction and reformation of the wicked. This principle, indeed, was avowed by the ancient *Mennonites*, but it is now almost wholly renounced: nevertheless, from this ancient doctrine, many of the religious opinions, that distinguish the *Mennonites* from all other Christian communities, seem to be derived: in consequence of this doctrine, they admit none to the sacrament of baptism, but persons that are come to the full use of their reason, they neither admit civil rulers into their communion, nor allow any of their members to perform the functions of magistracy; they deny the lawfulness of repelling force by force, and consider war, in all its shapes, as unchristian and unjust; they entertain the utmost aversion to the execution of justice, and more especially to capital punishments; and they also refuse to confirm their testimony by an oath. The particular sentiments that divided the more considerable societies of the *Mennonites* are the following: the rigid *Mennonites*, called the FLEMINGIANS, maintain, with various degrees of rigour, the opinions of their founder *Menno*, as to the human nature of Christ, alledging that it was produced in the womb of the Virgin, by the creating power of the Holy Ghost; the obligation that binds us to wash the feet of strangers, in consequence of our Saviour's command; the necessity of excommunicating and avoiding, as one would do the plague, not only avowed sinners, but also all those who depart, even in some light instances pertaining to dress, &c. from the simplicity of their ancestors; the contempt due to human learning, and other matters of less moment. However this austere system declines, and the rigid *Mennonites* are gradually approaching towards the opinions and discipline of the more moderate, or WATERLANDIANS.

The first settlement of the *Mennonites*, in the United Provinces, was granted them by William, prince of Orange, towards the close of the fifteenth century; but it was not before the following century, that their liberty and tranquility were fixed upon solid foundations, when, by a confession of faith, published in the year 1626, they cleared themselves from the imputation of those pernicious and detestable errors that had been laid to their charge. In order to appease their intestine discords, a considerable part of the Anabaptists of Flanders, Germany, and Friesland, concluded their debates in a conference held at Amsterdam, in the year 1630, and entered into the bonds of fraternal communion, each referring to themselves a liberty of retaining certain opinions. This association was renewed and confirmed by new resolutions, in the year 1649; in consequence of which the rigorous laws of *Menno* and his successors were, in various respects, mitigated and corrected. Mosheim's Eccl. Hist. vol. iv. p. 141, &c. vol. v. p. 46. 8vo.

MENOGENIEN, in *Botany*, a name by which some authors have called the *paonia*, or common garden piony.

MENOLOGY, MENOLOGIUM, from *μην*, *month*, and *λογ*, *discourse*, in the Greek church, is much the same with MARTYROLOGY, or CALENDAR, in the Latin.

The Greek *menologium* is divided into the several months in the year; and contains an abridgment of the lives of the saints, with a bare commemoration of the names of such whose lives were never written. The Greeks have various *menologia*; and the Romans tax them with inserting divers heretics, in their *menologia*, as saints.—Baillet treats of them at large.

MENSÆ *domesticæ*. See DOMESTICUS.

MENSALIA, MENSALS, such parsonages, or livings, as were formerly united to the tables of religious houses; and therefore by canonists called *mensal* benefices. See PARSONAGE and BENEFICE.

MENSARII, among the ROMANS, officers appointed to manage the public treasury, being sometimes three, and sometimes five in number.

MENSES, CATAMENIA, in *Medicine*, the monthly evacuations from the uterus of women not with child, or not giving suck.

They are so called from *month*, *mouth*, the period wherein they return. They are also called *flowers*, *courses*, &c. By the Jewish law, a woman was unclean while the *menstrual* blood flowed; and the man who touched her, or the moveables she had touched, was declared unclean. Levit. xv.

The *menses* make one of the most curious and difficult phenomena in the whole human body; for the explanation whereof, many *hypotheses* have been framed, though the matter is yet scarcely ascertained.

It is generally agreed by all, that the necessity women are under for some extraordinary supply to compensate the expence, and support them during the time of gestation, was the final reason why this redundance at other times was given them, which continues whilst this necessity subsists, and ceases when, according to the constitution of the female frame, it is no longer required: but this is all they agree in. Some, not content with this occasion alone, will have the *menstrual* blood offend in quality more than quantity; which they argue from the pain it gives many women in the evacuation; with many other idle notions.

Others ascribe this effect to an imaginary dominion of the moon over the bodies of women. This was formerly the prevailing opinion; though the smallest reflection would have shewn the weakness of it: for, had this purgation been owing to the influence of the moon, all women, of the same age and temperament, would have found it at the same periods and revolutions of the moon, &c. at the same time; which all experience shews to be false.

There are two other opinions, which carry with them great probability, and are argued with a great deal of strength and reason; in both which, the quality of the blood is allowed to be innocent, but they still differ about the reason of its issue. The former is that of Dr. Bohn and Dr. Freind, who maintain this flux to be the *result* of a *plethora*, or plenitude; and to be evacuated only for relief against the quantity.

Dr. Freind, who has maintained the cause of a *plethora* with the greatest strength and clearness, supposes, that this *plethora* arises from a concretation in the blood-vessels of a superfluity of aliment, which, he thinks, remains over and above what is expended by the ordinary ways; and that women have this *plethora*, and not men, because their bodies are more humid, and their vessels, especially the extremities of them, more tender, and their manner of living generally more inactive, than that of men; and that these things concurring, are the occasion that women do not perspire sufficiently to carry off the superfluous alimentary parts, till they be accumulated in such quantity as to distend the vessels, and force their way through the capillary arteries of the *uterus*. It is supposed to happen to women more than the females of other species, which have the same parts, because of the *erect* posture of the former, and the *worms*, and other canals, being perpendicular to the horizon; so that the pressure of the blood is directed towards their orifices: whereas in brutes they are parallel to the horizon, and the pressure wholly is on the sides of those vessels. The *discharge*, he thinks, happens in this part rather than in any other, as being more favoured by the structure of the vessels; the arteries being very numerous, and the veins sinuous and winding, and therefore more apt to retard the impetus of the blood; and consequently, in a plethoric case, to occasion the rupture of the extremities of the vessels, which may last, till, by a sufficient discharge, the vessels are eased of their overload.

This is the substance of Dr. Freind's theory; from whence he

he very mechanically and very philosophically accounts for the symptoms.

To his argument, why women have *menses* rather than men, we may add from Boerhaave, that, in the former, the *os sacrum* is wider, and ſtands farther out, and the *os coccygis* farther in; the *ossa innominata* wider, and farther apart, and the loweſt of them, as well as the lower eminences of the *os pubes*, farther outwards than in the latter. Hence, in women, the latitude or expanſion about thoſe bones, and the capacity of the *pelvis*, is vaſtly great in proportion to thoſe of men; and yet, in a woman not pregnant, there is not much to fill this expanſe. Again, the foreſide of the thorax is ſmoother in women than in men, and the blood veſſels, lymphaties, adipoſe and nervous veſſels, membranes, and fibres, are much laxer in women than in men: wherefore all their cavities, cells, veſſels, &c. are more eaſily repleniſhed, and the humours aggregated in them; beſides, that they are found to perſpire leſs than men, and to arrive much ſooner at their maturity, or *ætas* of increaſe. To which he adds the conſideration of the ſoft pulpous texture of the uterus, and the vaſt number of veins and arteries with which it is liſted.

Hence, a healthy maid, being arrived at her growth, begins to prepare more nutriment than is required for the ſupport of the body; which, as there is not to be any farther accretion, muſt of neceſſity fill the veſſels, and eſpecially thoſe of the uterus and breaſts, they being the leaſt compreſſed. Theſe will be dilated more than the others; whence the lateral veſcules evacuating their humour into the cavity of the uterus, it will be filled and extended. Hence a pain, heat, and heavineſs, will be felt about the loins, pubes, &c. the veſſels of the uterus, at the ſame time, will be ſo dilated, as to emit blood into the cavity of the uterus, and its mouth will be lubricated and ſoftened, and blood iſſue out. As the quantity of blood is diminiſhed, the veſſels will be leſs preſſed, and will contract themſelves again cloſer, ſo as again to retain the blood, and let paſs the groſſer part of the ſerum; till at length only the uſual ſerum paſſes. Again, there are more humours prepared, which are more eaſily lodged in veſſels once dilated; and hence the *menſes* go and return at various periods in various perſons.

This hypotheſis, however plauſible, is oppoſed by Dr. Drake, who maintains, that there is no ſuch repletion, or, at leaſt that it is not neceſſary to menſtruation; arguing, that, if the *menſes* were owing to a plethora ſo accumulated, the ſymptoms would ariſe gradually, and the heavineſs, ſtiffneſs, and inactivity, neceſſary ſymptoms of a plethora, would be felt long before the period were completed, and women would begin to be heavy and indiſpoſed ſoon after evacuation, and the ſymptoms would increaſe daily; which is contrary to all experience; many women, who have them regularly and eaſily, having no warning, nor any other rule to prevent an indecent ſurprize, than the meaſure of the time; in which, ſome that have ſlipped, have been put to confuſion and ſhifts, no ways conſiſtent with the notice a plethoric body would give. He adds, that, even in thoſe who are difficultly purged this way, the ſymptoms, though very vexatious and tedious, do not make ſuch regular approaches, as a gradual accumulation neceſſarily requires. If we conſider what violent ſymptoms come on in an hour, we ſhall be extremely puzzled to find the mighty acceſſion of matter, which ſhould, in an hour or a day's time, make ſuch great alterations. According to the hypotheſis, the laſt hour contributes no more than the firſt, and of conſequence the alteration ſhould not be greater in the one than in the other, ſetting aſide the bare eruption.

This is the ſubſtance of what is argued againſt Dr. Freind's theory; which, it muſt be owned, notwithſtanding theſe objections, is ſtill the moſt rational and conſiſtent that has yet been advanced.

Thoſe who oppoſe it, give into the doctrine of fermentation, and maintain the evacuation of blood in thoſe parts to be the effect of an effervescence or ebullition of the blood. This opinion has been maintained by many, particularly by Dr. Charleton, Bale, De Graaf, and Drake; the two firſt of whom ſuppoſe a ferment peculiar to the women, which produces this flux, and affects that part only, or at leaſt principally. Dr. *Graaf*, leſs particular in his notion, only ſuppoſes an effervescence of the blood, raiſed by ſome ferment, without aſſigning how it acts, or what it is. The ſudden turgeſcence of the blood occaſioned them all to think, that it aroſe from ſomething till then extraneous to the blood, and led them to the parts principally affected to ſeek for an imaginary ferment, which no anatomical inquiry could ever ſhew, or find any receptacle for, nor any reaſoning neceſſarily infer. Again, that heat, which frequently accompanies this turgeſcence, led them to think the caſe more than a plethora, and that there was ſome extraordinary inteſtine motion at that time.

Dr. Drake improves on the doctrine of a ferment; and contends, not only that it is neceſſary there ſhould be a ferment, but a receptacle alſo for this ferment; concluding, from the ſuddenneſs and violence of the ſymptoms, that a great quantity muſt be conveyed into the blood in a ſhort time, and conſequently, that it muſt have been ready gathered in ſome receptacle, where, while it was lodged, its action was reſtrained. But he goes farther ſtill, and pretends to aſcertain the place, &c. both of the one and the other, making the gall-bladder to be the receptacle, and the bile the ferment. This liquor he thinks well adapted to raiſe a fermentation in the blood, when diſcharged into it in a quantity; and, as it is contained in a receptacle that does not admit of a continual iſſue, it may be there reſerved, till, in a certain period of time, the bladder becoming turgid and full, through the compreſſion of the incumbent viſcera, it emits the gall; which, by the way of the lacteals, inſinuating itſelf into the blood, may raiſe that effervescence, which occaſions the aperture of the uterine arteries.

To confirm this, he alledges, that perſons of a bilious conſtitution have the *menſes* either more plentifully, or more frequently, than others; and that diſtempers, manifeſtly bilious, are attended with ſymptoms reſembling thoſe of women labouring under difficult menſtruation. If it be objected, that, on this principle, men ſhould have *menſes* as well as women, he anſwers, that men do not abound in bile ſo much as women, the pores of the former being more open, and carrying off more of the ſerous part of the blood, which is the vehicle of all the other humours; and, conſequently, a greater part of each is diſcharged through them than in women, wherein the ſuperfluity muſt either continue to circulate with the blood, or be gathered into proper receptacles; which is the caſe in the bile. The ſame reaſon he gives why menſtruation ſhould not be in brutes; the pores of theſe being manifeſtly more open than thoſe of women, as appears from the quantity of hair which they bear; for the vegetation whereof, a large cavity, and a wider aperture of the glands, is neceſſary, than where no ſuch thing is produced; yet there is ſome difference between the males and females even among theſe, ſome of the latter having their *menſes*, though not ſo often, nor in the ſame form and quantity, as women.

He adds, that the ſeveral phenomena of the *menſes*, whether in a natural, a regular, or diſeaſed caſe, flow naturally and readily from this hypotheſis; and that whatever may be accounted for from a plethora, or from any particular ferment, may, without any ſtraining, be applied to this.

Females generally begin to menſtruate about the age of fourteen or fifteen, and ceaſe about fifty; though inſtances have occurred of their commencing ſooner and continuing longer. There are, therefore, two critical periods in the lives of females, which require their particular attention. In order to eſcape the CHLOROSIS, and other ſimilar diſeaſes, incident to that period of life when the *menſes* commence, they ſhould avoid indolence and inactivity, and accuſtom themſelves to exerciſe in the open air, as much as poſſible. Unwholeſome food, dulneſs of diſpoſition, and ſtrait cloaths are very injurious to females at this ſeaſon. The diſcharge in the beginning is ſeldom ſo inſtantaneous as to ſurpriſe them unawares. The eruption is generally preceded by ſymptoms that indicate its approach; ſuch as a ſenſe of heat, weight, and dull pain in the loins; diſtenſion and hardneſs of the breaſts; head ach; loſs of appetite; laſſitude; paleneſs of the countenance; and ſometimes a ſlight degree of fever. When theſe ſymptoms occur, every thing ſhould be carefully avoided which may obſtruct the menſtrual flux, and all means uſed to promote it: as ſitting frequently over the fleams of warm water, drinking warm diluting liquors, &c. When the *menſes* have begun to flow, great care ſhould be taken to avoid every thing that tends to obſtruct them; ſuch as filth, and all kinds of food that are hard of digeſtion, and cold, acid liquors. Cold is likewiſe hurtful at this period, as alſo anger, fear, grief, and other affections of the mind: from whatever cauſe this flux is obſtructed, except in the ſtate of pregnancy, proper means ſhould be uſed to reſtore it: and if exerciſe in a dry, open, and rather cool air, wholeſome diet, generous liquors in a weak and languid ſtate of the body, cheerful company, and amuſement fail, recourſe muſt be had to medicine. When obſtructions proceed from a weak relaxed ſtate of the ſolids, ſuch medicines as tend to promote digeſtion, to brace the ſolids, and aſſiſt the body in preparing good blood, ought to be uſed. The principal of theſe are iron and Peruvian bark, with other bitter and aſtringent medicines. Filings of iron may be infuſed in wine or ale, two or three ounces to a

quart; and after it has ſtood for two or three weeks, it may be filtered, and about half a wine glaſs of it taken twice a day: or, prepared ſteel may be taken in the doſe of half a dram, mixed with a little honey or treacle, three or four times a day. As the breathing of ſome patients is affected by the uſe of iron, the following form of adminiſtering it will generally ſucceed: ℞ lim. mart. ʒvi. gum. ammon. ſapon. Venet. ad ʒſi. ſpec. arom. ʒi. aloes ʒß. ſyrup. q. ſ. f. pil. mediocr. The bark and other bitters may be taken in ſubſtance or infuſion, as is moſt agreeable to the patient. When obſtructions proceed from a viſcid ſtate of the blood, and for women of a groſs or full habit, evacuations, and ſuch medicines as attenuate the humours, are neceſſary. The patient in this caſe ought to be bled, to bathe her feet frequently in warm water, to take now and then a cooling purge, and to live upon a ſpare thin diet. Her drink ſhould be whey, water, or ſmall beer, and ſhe ought to take ſufficient exerciſe. A tea-ſpoonful of the tincture of black hellebore may alſo be taken twice a day in a cup of warm water. The ſal diureticus may be given from ʒß to ʒji, three times a day. A ſtuggiſh, viſcid ſerum, may alſo be corrected by repeated doſes of tinctura ſacra, or of the pil. Ruſſ. adminiſtered ſo as to keep the bowels from coſtiveneſs. When the head-ach and ſickneſs in the ſtomach affect the patients, Dr. Aſton extols the uſe of borax, given in a fluid ſtate. Opiates are often very uſeful for removing thoſe ſpaſms which are excited by a painful approach of the *menſes*, and which frequently retard or obſtruct their courſe. This caſe of painful menſtruation deſerves particular attention; becauſe it impairs the health of patients by its preſent effects, and ſeems to render them leſs prolific in future. Dr. Fothergill has afforded relief to ſeveral by the following proceſs: let the patient have by her a few pills, conſiſting of extr. theb. gr. i. each, made ſoft with a little of any kind of conſerve. She is to take one of theſe pills the moment ſhe finds the pain attending this diſcharge coming on. A pill may be taken every hour till the pain goes off; and more than two of theſe pills will ſeldom be required; but it muſt be taken in ſuch a quantity as to mitigate the pain. Let the patient keep either in or upon the bed, at leaſt in a recumbent poſture; drinking moderately of any diluting liquor, as the herb teas, weak whey, or thin broth. When the time is paſt, a coarſe of chalybeate bitters, in ſmall doſes, may be continued, till within a few days of the return; and the belly ſhould be kept open by ſome proper laxative; two or three grains of cathart. extract. with half the quantity of calx antimonii illota, taken every night, will often ſucceed perfectly well. This excruciating pain ſeems to be ſpaſmodic, and to proceed from the extreme irritability of the uterine ſyſtem. In caſes, both of the retention and ſuppreſſion of the *menſes*, i. e. when they do not begin to flow at the period of life in which they may be expected, and when they ceaſe, from other cauſes beſides conception, to return at their uſual and proper periods, the application of electricity is a very efficacious and certain remedy. Mr. Birch, in his Conſiderations on the Efficacy of Electricity for removing Female Obſtructions, 1779, has enumerated ſeven caſes, in which the electrical power has been very ſucceſsfully employed. With reſpect to the mode of applying this remedy, Mr. Cavallo, in his Eſſay on the Theory and Practice of Medical Electricity, 1780, p. 63, ſays, that ſmall ſhocks, i. e. of about one-twentieth of an inch, may be ſent through the pelvis; ſparks may be taken through the cloaths from the parts adjacent to the ſeat of the diſeaſe; and alſo the electric fluid may be tranſmitted, by applying the metallic or wooden extremities of two directors (ſee ELECTRICITY) to the hips, in contact with the cloaths, part of which may be removed, in caſe they are too thick. The number of ſhocks may be about twelve or fourteen; the other applications may be continued for two or three minutes. But either ſtrong ſhocks, or a ſtronger application of electricity than the patient can conveniently bear, ſhould be carefully avoided; for by thoſe means, ſometimes more than a ſufficient diſcharge is occaſioned, which is not eaſily cured.

Mr. Birch adviſes one of the directors to be introduced through the pocket, or down the back of the ſtays, ſo as to reach to the lower part of the ſpine, nearly upon the os ſacrum, while the other is placed below the peak of the ſtays. When the directors are thus ſituated, the ſhock is expected to paſs immediately through that part of the pelvis which is included between the directors. One of them is then removed from under the peak of the ſtays, and placed under one foot, and afterwards under the other. Some lateral ſtrokes are afterwards tranſmitted acroſs the pelvis, after having introduced a director through each pocket hole.

When the obſtruction of the *menſes* is the effect of other maladies, inſtead of giving medicines to force that diſcharge, which might be dangerous, endeavours ſhould be uſed to reſtore the patient's health and ſtrength. When that is effected, the other will return of courſe.

When the menſtrual flux is too great, the patient becomes weak, the colour pale, the appetite and digeſtion are bad, and oedematous ſwellings of the feet, dropſies, and conſumptions, often enſue. This frequently happens to women about the age of forty-five or fifty, and is very difficult of cure. It may proceed from a ſedentary life; a full diet, conſiſting chiefly of ſalted, high ſeaſoned, or acrid food; the uſe of ſpirituous liquors; exceſſive fatigue; relaxation; a diſſolved ſtate of the blood; violent paſſions of the mind, &c. In order to reſtrain the flux, the patient ſhould be kept eaſy both in body and mind. If it be very violent, ſhe ought to lie in bed with her head low; to live upon a cool and ſlender diet, as veal or chicken broths, with bread, and to drink decoctions of nettle roots, or the greater comfrey. If theſe fail, ſtronger aſtringents may be uſed, as Japan-earth, alum, elixir of vitriol, the Peruvian bark, &c. Dr. Buchan directs two drams of alum, and one of Japan-earth, to be pounded together, and divided into eight or nine doſes, one of which may be taken three times a day. Perſons whoſe ſtomachs cannot bear the alum, may take two ſpoonfuls of the tincture of roſes three or four times a day, to each doſe of which ten drops of laudanum may be added. If theſe ſhould fail, half a dram of the Peruvian bark, in powder, with ten drops of the elixir of vitriol, may be taken in a glaſs of red wine four times a day.

The diſcharge of the *menſes* is interrupted naturally during pregnancy; but this is not always the caſe, becauſe ſome have them three months, ſome ſix months, and ſome during the whole time of geſtation, though in leſs quantity than at other times. The *menſes* are moſtly interrupted during the time of giving ſuck; though many women have a return about the third or fourth month after delivery, and almoſt all have them again in the ninth or tenth month. In caſes of obſtruction, the menſtrual blood hath diſcharged itſelf by other outlets.

It uſually happens that this periodical diſcharge ceaſes between the age of forty and fifty; and the ſeaſon in which this takes place, is critical to the ſex. However, thoſe who ſurvive this period, without contracting any chronical diſeaſe, become more healthy and vigorous than they were before. About this time, ſome are afflicted with the well-known ſymptoms of plethora, heat, ſhuſhings, reſtleſs nights, troubleſome dreams, and unequal ſpirits; others are attacked with inflammations of the bowels, or other internal parts; ſpaſmodic affections of various parts, ſtiffneſs in the limbs, ſwelled ancles, with pain and inflammation, the piles, and other effects of plenitude. Thoſe of full plethoric habits, accuſtomed to copious evacuations, will find great relief by bleeding frequently in moderate quantities, keeping the bowels lax, moderating their diet, and uſing ſufficient exerciſe, that is not too heating. If an immoderate flux of the *menſes* happens at this period, it ſhould be reſtrained by gentle laxatives, cooling medicines, reſt, anodynes, a moſt ſparing not too liquid diet, rather than by very copious bleedings and aſtringents of any kind. Dr. Fothergill obſerves, that various purgations of aloes, the tinctura ſacra, pil. Ruſſ. elixir proprietatis, and other compoſitions of this kind, are recommended, as proper purgatives to be uſed on the ceſſation of the *menſes*. But many inconveniences have ariſen from theſe heating medicines; as the piles, ſtrangury, immoderate diſcharges of the *menſes*, racking pains in the loins, and other ſimilar complaints. Rhubarb, ſena, magneſia, ſulphur medicines, ſmall doſes of jalap, and various combinations of theſe, may be ſubſtituted in the room of the others, and will ſupply ſufficient variety to the preſcriber and patient. When the *menſes* are about to go off, they appear for the moſt part irregularly both in time and quantity; once in a fortnight, three, five, or ſix weeks; ſometimes very ſparingly, at other times in immoderate quantities. Great loſſes of this kind are often prevented by taking away four or five ounces of blood, a few days after the firſt menſtrual ſuppreſſion. If a patient has in early life been ſubject to cutaneous eruptions, ſore eyes, glandular ſwellings, or other obvious marks of morbid humours ſubſiſting in the conſtitution, and all which may have diſappeared about the time the *menſes* became regular, an iſſue is an adviſeable drain, and may prevent many inconveniences. If at this time ulcerous ſores break out about the ancles, or in other parts of the body, they ought to be continued open, or artificial drains ſubſtituted in their ſtead; for thoſe who will have them dried up are ſoon after carried off by acute diſeaſes, or fall into thoſe of a chronic nature. Buchan's Dom. Med. chap. xlviii. London. Med. Obſ. art. 17.

MENSIS. See MONTH.

MENSIS *chymicus*. See MENSTRUUM.

MENSIS *veterus*. See FENCE *month*.

MENSORES, among the Romans, harbingers or officers, whose business it was to go and fix upon lodgings for the emperor, when he took a journey to any of the provinces. Their office was also to mark out encampents, and assign every regiment its post.

MENSORES also signified land-surveyors, architects, or appraisers of houses and public buildings. Those likewise who distributed the provisions in the army, were called *mensores frumentarii*; and servants who waited at table had the appellation of *mensores*.

MENSORES was likewise the title of officers among the Romans appointed to receive the provisions brought to the city by sea, and to see them carefully laid up and preserved in public granaries, of which there were great numbers.

MENSTRUAL, or MENSTRUOUS, a term in *Medicine*, applied to the blood which flows from women in their ordinary monthly purgations. See MENSES.

MENSTRUAL *epacts*. See EPACT.

MENSTRUAL *longitude of the moon*. See ARGUMENT.

MENSTRUUM, SOLVENT, or DISSOLVENT, in *Chemistry*, any liquor that will dissolve, that is, separate the parts of hard bodies.

The term takes its rise from this, that some chemists pretend, the complete dissolution of a mixed body cannot be effected in less than forty days; which period they call a *philosophical month*.

Aqua regalis is a *menstruum* for gold; aqua fortis, and spirit of nitre, for most other metals; and common water for salts, &c.

Menstruum is properly defined a body, which, being applied to, or intermixed with another, does so dissolve it, as that all the dissolving parts float among the parts dissolved, and so divides it into its minutest parts, as that the parts of the dissolvent are intermixed with those of the body dissolved. Whence it appears, that every *menstruum*, in dissolving a body, is likewise dissolved itself; so as, with the body it dissolves, to make up one body.

MENSTRUUMS may be divided into two classes: the first consists of such as are fluid; the second of such as are solid; that is, they are either actually divided, or they must be so before they act.

MENSTRUUMS, *fluid*, are, water, dew, oils, saline and acid spirits, alkalies, salts, &c.

MENSTRUUMS, *solid*, are such as must be made fluid before they will dissolve: such are most salts, nitre, vitriol, &c.

All *menstruums*, at the time they act as such, that is, at the time they are dissolving, act as fluids; whether such *menstruum* be a fluid, or a solid. Thus, e. g. silver is a *menstruum* with regard to gold; for if you take an ounce of silver, melt it in the fire, and add a grain of gold, all the parts of the silver will intermix themselves with the parts of the gold; so as that the gold and silver, which before were separate, now make but one mass. But gold and silver are only *menstruums* as they are dissolved by the fire; i. e. as they are rendered fluid.

As many more things might be done in chemistry than we now find practicable if we had more *menstruums* than are at present known, it must be a subject of infinite use in chemistry to discover new ones. To this purpose let it be considered, that in whatever way salts are united with other salts, new *menstruums* are produced by the mixture.

Thus if pure alkali be added to a solution of sea-salt, earthy matter is precipitated, and the salt afterwards obtained by crystallization, from the clear liquor, will be a sea-salt much purer than before, and capable of acting on bodies in a different manner.

The same fixed alkali being added to the brine of nitre, makes the liquor thick and milky, and precipitates an earthy matter; after which the nitre, obtained by crystallization, is much purer than before.

When fixed alkali is added to the brine of sal ammoniac, it lays hold of the acid of that salt, and sets the volatile alkali of the composition free, and suffers it to fly off in the air, leaving only a very pure and fixed sea-salt at the bottom of the vessel. If a pure volatile alkali be added to the brine of sea-salt, it makes the liquor thick, then purifies it, and flies off; and it does the same when added to a solution of nitre; and when added to a solution of sal ammoniac, it, in like manner, purifies the salt without altering its nature, and flies off as it was poured on. Vegetable acids produce but little alteration on being mixed with sea-salt, nitre, and sal ammoniac. Fermented vegetable acids, even after being purified by distillation, produce no great alteration when mixed with the same salts. If calcined vitriol, or alum, be mixed with nitre and distilled, they yield aqua fortis, which contains nothing of the acid of vitriol, or alum, but is a mere spirit of nitre; and if mixed with sea-salt, and treated in the same manner, the produce is a spirit of salt; and if with nitre and sea-salt together, they make an aqua regia. So if nitre and calcined vitriol be melted together in an open fire, the acid of the nitre is discharged, and a kind of tartarum vitriolatum is left behind. Sea-salt, treated in the same manner, leaves a sort of Glauber's salt behind; and, in general, what way soever it be by which salts are joined with salts, new saline productions, and new *menstruums* will arise; whence the art of chemistry may be perpetually improved, and new *menstruums* will give new phenomena on different bodies. New *menstruums* of particular virtues may also be made, by variously combining the known *menstruums* together; and this may be done by an almost infinite variety of ways: much may be also done by reducing every known *menstruum* to its utmost degree of purity. And, lastly, by reducing some of them into the minutest particles they can be reduced to, whether by art or nature; for upon these three particulars the extraordinary skill of the chief chemists seems principally to depend. For instance, suppose an extremely pure, strong, and subtle fermented vegetable acid was wanting: take fine verdigrise prepared from copper corroded by the subtile vapour of a fermenting acid; add to it twenty times its weight of the strongest distilled vinegar that can be made; digest them together, till the verdigrise is thoroughly dissolved, and the whole become a deep green liquor; purify this by filtration, and inspissate it over a gentle fire to a pellicle; set it in a quiet place, where it will shoot into crystals like emeralds, consisting of an acid vinegar and dissolved copper; pour off the liquor, collect the crystals, and evaporate as before; and by this means collect all the crystals that can be obtained; then dry these, and distil them in a retort, and the produce will be a most pure and strong vegetable acid, not in the least partaking of the nature of copper. But this experiment will not succeed with lead, tin, or any other of the metals soluble in vinegar; for the copper attracts the acid from of its water, and again restores it unaltered; but the others, though they equally attract and separate it, yet always yield it mixed and impure. Zwelfer imagined this acid to be the alkahest, or universal dissolvent; but Tachenius soon proved that it was no other than distilled vinegar of a much greater purity than usual.

To shew that by the compounding one *menstruum* with another, new, and often excellent salts may be produced, let it be considered, that the regenerated tartar, properly prepared, may be intimately united to a pure alcohol, and thus produce a vegetable *menstruum*, composed by the most close union of the most subtile vegetable particles, viz. alkali, acid, and sulphur; whence the effect of such a liquor cannot but be extremely great, both as a *menstruum* and a medicine. So again, if a pure strong alkaline spirit be united with pure alcohol, it produces an admirable *menstruum*, called the ossa Helmontii, which intimately dissolves distilled vegetable oils, and thus makes a *menstruum* compounded of the genuine vegetable sulphur, and an alkali, and is perhaps one of the best medicines, as well as the best *menstruums*, hitherto known.

In like manner pure spirit of nitre saturated with the alkaline spirit of sal ammoniac, makes a kind of volatile nitre, and thus affords an opportunity of examining, by experiments, whether the great things expected from a volatile nitre, by the chemists, will be performed by it or not. Experiments of this kind are extremely worth prosecuting. It is not certain whether any *menstruum* will dissolve any substance without the assistance of fire, as no experiment could ever be made in any place destitute of all fire; there being evidently fire in our utmost known degree of cold; and we all know that *menstruums*, of whatever kind, act greatly the better for being assisted by heat.

Menstruums can scarce act as such, unless reduced to a fluid form, or at least approaching thereto; this is chiefly given them by means of fire, air, water, and trituration. These are the four causes which usually excite the latent powers of *menstruums*. Certain *menstruums* contain a cause within themselves apparently capable of exciting motion, though in reality it depends upon the near approach of some other body. Thus, strong spirit of nitre confined in a close vessel, yields an acid fume constantly playing about the surface of the liquor, and issuing out whenever the vessel is unstopped. So also the alkaline spirit of sal ammoniac yields a fume never observed to be at rest; and the spirit of this salt, made with lime, yields a fume much more volatile and moveable: all the bodies of this kind therefore strangely retain, and strangely excite motion. We are always to remember also that air, even in the coldest places, has always a strong vibratory motion,

motion, and therefore may often excite thefe motions in thefe bodies; as on the other hand folutions are often immediately performed by means of the motion peculiar to the *menftruum* arifing from it; while another motion of a different kind, and proceeding from a different caufe, would not produce the effect. Thus, for inftance, if a fine piece of Engliſh chalk be calcined in a ſtrong fire, or even in the focus of a burning-glaſs, it will ſcarce alter its nature by this violent motion, nor again by being expoſed to a hot or cold air, either at reſt, or agitated by winds; and though if long boiled in water, or a brine of ſalt of tartar, it will not diſſolve; yet if immediately melts and diſappears when put into cold vinegar; whence we ſee there is a very great difference between the motion excited by the reciprocal force of the ſolvent and ſolvend, and the motion excited by fire, air, water, and impulſe. The acrimony of a *menftruum*, with reſpect to a human body, ſo as to excite pain, corrode or conſume the parts thereof, is no ſign that ſuch a *menftruum* is fuited to diſſolve other bodies, as appears from oil of vitriol, ſpirit of nitre, ſpirit of ſalt, and aqua regia, which though they readily conſume flefh, yet do not conſume or diſſolve wax and ſulphur, though theſe two may be eaſily diſſolved in the body. Many bodies incapable of ſolution in certain *menftruums*, may be fuited for diſſolving therein, by being previouſly diſſolved in other *menftruums*. Thus if common ſulphur be boiled ever ſo long in alcohol, it diſſolves no more than a ſtone in water; but if the ſulphur be firſt melted with ſalt of tartar into a ſhiky maſs, the alcohol will then diſſolve it: ſo alſo powdered antimony remains untouched after boiling in alcohol; but if firſt boiled to a dry maſs in an alkaline lixivium, this maſs preſently yields a golden tincture to alcohol. Some chemiſts have conceived ſo highly of this regular and ſucceſſive application of different *menftruums*, particularly Mr. Boyle and Mr. Homberg, that they ſay even metals may by this means be reſolved into their component running mercury and fixing ſulphur. Thus they aſſert, that if ſilver be firſt diſſolved in ſpirit of nitre, and then long digeſted with pure fixed alkali, and afterwards ſeveral times ſublimed with ſal ammoniac, it will at length, by means of theſe reſuſcitating ſalts, afford a true running mercury; in which operation the acids procure an entrance for the alkalies into the ſubſtance of the metal; as the fixed alkalies procure admiſſion to the volatile ones, which elſe could not enter. Boerhaave waves diſputing upon the point, whether the metals can be thus reſolved into their running mercuries, and only affirms, that after many trials, he was never able to effect it. Boerh. Chem. part i. p. 362, ſeq.

It is an error to think a *menftruum* cannot be too ſtrong. Oil of vitriol diluted with ſeveral times its weight of water, diſſolves iron beſt. So aqua fortis diluted, works beſt in lead. And Mr. Boyle makes the like obſervation as to the ſolution of ſilver.

MENSTRUUM, *animal*. There are of the animal *menftruums* very many both of the natural and artificial kind; the natural are blood, ſerum, gall, urine, ſaliva, rennet, whey, butter-milk, &c. moſt of which, being properly employed, will either produce or diſcharge colours, and might be made ſerviceable in the painting and dying trades. Thus recent urine diſcharges the common ink out of linen, &c. Blood affords, by proper management, the noble Pruſſian blue; and gall is a natural yellow, well deſerving to be treated in the manner of blood in that preparation. Of the artificial kind are the ſpirit of urine produced by chemiſtry, which ſerves to produce, alter, and deſtroy a vaſt number of colours. The liquors diſtilled from recent, or fermented whey, butter-milk, &c. might be alſo found of great value; and variouſly compounding theſe ſeveral animal ſubſtances, even by random trials, or chance experiments, new diſcoveries in colours might be made; though much more, probably, by a right reaſoning and analogy. As, for inſtance, the common bones burnt to a blackneſs, being found to afford the bone black, the experiment was eaſily tranſferred to ivory, and ſo the ivory black was diſcovered: and ſo of the reſt. Shaw's Lectures, p. 183.

MENSTRUUM *peracutum*. Mr. Boyle gives the name of *menſtruum peracutum* to a *menſtruum* made by pouring on the rectified oil of butter of antimony as much ſtrong ſpirit of nitre as would ſerve to precipitate out of it all the bezoarticum minerale; and then with a ſmart fire diſtilling off the liquor which would come over, and cohobating it upon the antimonial powder. Works Abr. vol. i. p. 260. 377.

He put ſome highly refined gold into a large proportion of this *menſtruum peracutum*, where it diſſolved ſlowly and quietly; and he found at the bottom of the glaſs a conſiderable quantity of a white powder, which the *menſtruum* would not touch, and which was alſo indiſſoluble in aqua regia. The ſolution of gold being abſtracted, and the gold again reduced into a body, yielded, upon a ſecond ſolution, more of the white powder. This powder he melted down into a metal, anſwering in colour, malleability, ſolubility in aqua fortis, and in bitterneſs to the taſte of that ſolution, to ſilver. Hence he infers, that notwithſtanding the ſuppoſed unchangeableneſs of gold, this experiment ſhews it to be really changeable into ſilver, or at leaſt into a new kind of metal very different from gold. And he therefore concludes, that there is no impoſſibility in the nature of the thing, that one metal ſhould be tranſmuted into another. Ibid. p. 260. 262.

By diſſolving gold in this *menſtruum peracutum*, Mr. Boyle alſo tells us, he made the gold riſe in the retort, in the top and neck of which it was found in the form of yellow and reddiſh ſublimate. Works Abr. vol. i. p. 263. 377. See PHILOSOPHER's *ſtone*.

MENSTRUUM, *univerſal*. See ALKAHEST.

MENSTRUUMS, *as to the action of*, Sir Iſaac Newton accounts for it from the acids wherewith they are impregnated. The particles of acids are found to be endued with a ſtrong attractive force, wherein their activity conſiſts, and by virtue whereof they diſſolve bodies. Theſe acids he ſuppoſes of a middle nature between water and hard bodies, and to attract both. By this attraction they gather together about the particles of bodies, whether metallic, ſtony, or the like, and adhere to them very cloſe, ſo as ſcarce to be ſeparable from them by diſtillation, or ſublimation. Thus ſtrongly attracted, and gathered together on all ſides, they raiſe, diſjoin, and ſhake aſunder, the particles of bodies, i. e. they diſſolve them; and by the attractive power whereby they ruſh againſt the particles of the bodies, they move the fluid, and ſo excite heat, ſhaking ſome of the particles to that degree, as to convert them into air, and ſo generating bubbles. See ACID.

Dr. Keil gives us the theory or foundation of the action of *menſtruums*, in ſeveral propoſitions; which the reader may find recited under the article ATTRACTION. See alſo FERMENTATION.

From thoſe propoſitions we ſee the reaſons of the different effects of different *menſtruums*; why ſome bodies, for inſtance, metals, diſſolve in a ſaline *menſtruum*: others again, as reſins, in a ſulphureous one, &c. particularly why ſilver diſſolves in aqua fortis, and gold only in aqua regalis; all the varieties whereof are accountable for, from the different degrees of cohæſion, i. e. of attraction in the parts of the body to be diſſolved, the different diameters and figures of its pores, the different degrees of attraction in the *menſtruum*, and the different diameters and figures of its parts.

Suppoſe, e. gr. the attraction of gold to that of ſilver to be as a to b; and of ſilver to aqua fortis as b to d; but that of aqua fortis to aqua regia as d to e; let f ſignify the magnitude of particles in aqua fortis, and r thoſe in aqua regia; c the cohæſion of gold, and g the cohæſion of ſilver: if the diameters of the particles f be greater than the diameters of the pores of gold, they can never diſſolve the gold, let their attractive force be ever ſo ſtrong. But if $b-f\times d$ be greater than g, then the ſilver will yield to the *menſtruum* whoſe particles are f, and leſs than the pores of ſilver; and if $b-e\times r$ be leſs than g, the ſilver will never diſſolve in the *menſtruum*, the particles whereof are r, and the attractive force e. But if $a-c\times r$ be greater than c, the *menſtruum* made up of the particles r, and whoſe attractive force is e, will be able to penetrate and diſſolve the gold.

How a *menſtruum* may ſuſpend bodies much heavier than itſelf, which very often happens, may be conceived by conſidering, that the parts of no fluid can be ſo eaſily ſeparated, but they will a little reſiſt, or retard the deſcent of any heavy bodies through them; and that this reſiſtance is, *ceteris paribus*, ſtill proportionable to the ſurface of the deſcending bodies; but the ſurfaces of the bodies do by no means increaſe, or decreaſe, in the ſame proportion as their ſolidities do; for the ſolidity increaſes as the cube, but the ſurface only as the ſquare of the diameter. Small bodies, therefore, will have much larger ſurfaces, in proportion to their ſolid contents, than larger bodies will; and conſequently, when exceedingly diminiſhed, may eaſily be buoyed up in the liquor.

For a fuller account of the nature and operation of different *menſtrua*, ſee DISSOLVENT, DISSOLUTION, SOLVENT, and SOLUTION.

MENSTRUUM, in *Pharmacy*, chiefly denotes a body that will extract the virtues of ingredients by infuſion, decoction, or the like. See EXTRACT, INFUSION, and DECOCTION.

MENSURATION, the act, or art, of MEASURING.

MENTAL, ſomething that relates, or is reſtrained, to the operation of the underſtanding.

Thus,

Thus, a *mental* prayer is ſuch a one as is made merely in the mind, without pronouncing one word of it.

Mental reſervations are the refuge of hypocrites. See RESERVATION.

MENTHA, in *Botany*. See MINT.

MENTUM, in *Anatomy*, the lower part of the FACE, beneath the mouth; which we otherwiſe diſtinguiſh by the name of *chin*.

MENTZELIA, in *Botany*, a genus of the *polyandria monogynia* claſs. Its characters are theſe: the flower has five petals, ſomewhat longer than the five-leaved ſpreading empalement, and many erect briſtly ſtamina; from the long cylindrical germen, which is ſituated under the flower, ariſes a briſtly ſtyle; the germen turns to a cylindrical long capſule, with one cell, containing many ſmall ſeeds. There is one ſpecies, a native of La Vera Cruz.

MENYANTHES, in *Botany*. See *Bog*-BEAN.

MEPHITIS, or MEPHITICAL *exhalation*, denotes a poiſonous and noxious ſteam iſſuing out of the earth. See DAMP and *Mephitic* AIR. See alſo EFFLUVIA, and GROTTO *del Cane*.

MEPHITIS, in *Mythology*, is a name given to Juno, becauſe ſhe is ſuppoſed to preſide over ſtinking exhalations, or corrupted and noxious air; and hence it was uſed to ſignify ſuch noxious air itſelf. According to Scaliger, the word is Etruſcan, and derived from the Syrians, with whom it ſignified any ſtinking ſmell. Juno had a temple among the Hirpines under this appellation.

MER.—*Outre le* MER. See OUTRE.

MERCATOR's *chart*, or *projection*, is a ſea-chart, or projection of the ſurface of the earth in plano.

For the conſtruction, uſe, advantages, &c. of which, ſee *Mercator's* CHART.

MERCATOR's *ſailing*, is that performed loxodromically, by means of *Mercator's* charts. See *Mercator's* SAILING.

MERCATORUM *feſtum*, among the Romans, a feſtival kept by the mercantile people on the ides or 15th of May, in honour of Mercury, to whom they ſacrificed a ſow; then ſprinkling themſelves with the water of a fountain called *aqua Mercurii*, they prayed the God to proſper their trade.

MERCHANT, *mercator*, is one who buys and trades in any things: and as merchandize includes all goods and wares expoſed to ſale in fairs or markets; ſo the word *merchant* formerly extended to all ſorts of traders, buyers, and ſellers. But every one that buys and ſells is not at this day under the denomination of a *merchant*; only thoſe who traffick in the way of commerce, by importation or exportation, or carry on buſineſs by way of barter or exchange, and who make it their living to buy and ſell, by a continued aſſiduity, or frequent negociation in the myſtery of merchandizing, are eſteemed *merchants*. Thoſe who buy goods, to reduce them by their own art or induſtry, into other forms than they are of, and then to ſell them, are artificers and not *merchants*. Bankers, and ſuch as deal by exchange, are properly called *merchants*. Lex. Mercat. or Merch. Com. 23.

The *mercantile* profeſſion is eſteemed noble, and independent. In France, by two arrets of Louis XIV. the one of 1669, the other of 1701, the nobility are allowed to trade, both by land and ſea, without derogating from their nobility: and we have frequent inſtances of merchants ennobled in that country, in regard of the utility of their commerce, and the manufactures they have ſet up. In Bretagne, even a retail trade does not derogate from nobility.

When the nobles of that province are diſpoſed for commerce, they let their nobility ſleep; that is, they do not loſe it, but only ceaſe to enjoy the privileges of their nobleſſe while their commerce continues; and re-aſſume it, on their giving over trade, without any letters or inſtrument of re-habilitation.

In republics trading is ſtill more valued; but no where more than in England, where the younger ſons and brothers of the beſt families are frequently bred up to *merchandize*. Add to this, that many of the Italian princes are the principal merchants of their ſtates; and think it no diſcredit to make their palaces ſerve as warehouſes: and that many of the kings of Aſia, and moſt of thoſe of the coaſt of Africa and Guinea, traffick with the Europeans, ſometimes by their miniſters, and ſometimes in perſon.

There are companies of *merchants* in London for carrying on conſiderable joint trade to foreign parts. See COMPANY.

Beſides theſe companies, there are other *merchants*, who are diſtinguiſhed by the country to which they trade; as Dutch *merchants*, who trade to the Weſt Indies; Canary and Portugal *merchants*; Italian *merchants*, who trade to Legborn, Venice, &c. French, and Spaniſh *merchants*.

The law of England, as a commercial country, pays a very particular regard to foreign *merchants*, in innumerable inſtances. Thus it is provided by Magna Charta, c. 30. that all *merchants*, unleſs before hand publicly prohibited, ſhall have ſafe-conduct to depart from, to come into, or tarry in, and to go through England, for the exerciſe of *merchandize*, without any unreaſonable impoſts, except in time of war: and if a war breaks out between us and their country, they ſhall be attached, if in England, without harm of body or goods, till the king, or his chief juſticiary, be informed how our *merchants* are treated in the land with which we are at war; and if our's are ſecure in that land, they ſhall be ſecure in our's. Upon which Monteſquieu remarks, with admiration, that the Engliſh have made the protection of foreign *merchants* one of the articles of their national liberty: and alſo, that the Engliſh know better than any other people upon earth, how to value at the ſame time theſe three great advantages, religion, liberty, and commerce. In this reſpect their diſpoſition is very different from the genius of the Roman people; who, in their manners, their conſtitution, and even in their laws, treated commerce as a diſhonourable employment, and prohibited the exerciſe of it to perſons of birth, rank, or fortune; and equally different from the bigotry of the canoniſts, who looked on trade as inconſiſtent with Chriſtianity, and determined at the council of Melfi, under pope Urban II. A. D. 1090, that it was impoſſible with a ſafe conſcience to exerciſe any traffick, or follow the profeſſion of the law. See COMMERCE.

If a difference ariſe between the king and any foreign ſtate, alien *merchants* are to have forty days notice, or longer time, to ſell their effects and leave the kingdom. 27 Ed. III. cap. 17.

The principal qualifications requiſite for the profeſſion of a *merchant*, are, 1. To know how to keep books ſingle or double, viz. journals, ledgers, and others. 2. To draw invoices, contracts, charter-parties, policies of aſſurance, bills of exchange, letters miſſive, &c. 3. To know the relation between the money, weights, and meaſures, of ſeveral countries. 4. To know the places where the ſeveral kinds of *merchandize* are manufactured, in what manner made, what the materials compoſed of, and whence; the preparation the materials require before they are wrought; and the *merchandizes* afterwards. 5. The lengths and breadths of ſtuffs, as ſilks, wools, hairs, linens, &c. the regulations of the places where they are manufactured; and their different prices at different ſeaſons. 6. The dying; and the ingredients for the formation of the different colours. 7. The *merchandizes* that abound, or are more rare, in one country than another; their kinds and qualities; and the manner of trafficking in them to the beſt advantage, whether by land, by ſea, or rivers. 8. The commodities permitted or prohibited, both for the import and export of a ſtate. 9. The price of exchange, according to the courſe of ſeveral places, and what it is that raiſes or lowers it. 10. The duties to be paid, both at the import and export of wares, according to the uſage of the place, the tariffs, regulations, &c. 11. The manner of packing, bailing, and tunning *merchandizes*, to keep them either in magazines, or in voyages, &c. 12. On what terms a merchant-veſſel may be freighted and inſured. 13. The goodneſs and value of every thing requiſite for the conſtruction or reſitting of veſſels, the prices of woods, cordage, maſts, anchors, ſails, and other neceſſaries. 14. The wages ordinarily given captains, officers, and ſailors; and the manner of contracting with them. 15. The foreign languages, which may be reduced to four principal ones; viz. the Spaniſh, uſed almoſt through all the Eaſt, particularly on the coaſt of Africa, from the Canaries to the Cape of Good Hope; the Italian, uſed throughout the coaſts of the Mediterranean, and many places of the Levant; the Teutonic or German, uſed throughout moſt countries of the North; and the French, which is now become almoſt univerſally current. 16. The conſular juriſprudence, the laws, cuſtoms, companies, colonies, chambers of inſurance, conſulates in the ſeveral countries; and, in general, all the ordinances, regulations, and policies, relating to commerce.

MERCHANT *court*, or *Court* MERCHANT, a kind of judicatory power, inveſted in *merchants*, choſen for that purpoſe, in ſeveral parts of Europe; in order to decide and determine in a ſummary way, all differences and litigations, among themſelves and their dependents.

The affairs of *merchants* are accompanied with ſuch variety of circumſtances, ſuch new and unuſual contingencies, which change and differ in every age, with a multitude of nicetics and punctilios; and theſe again altering, as the cuſtoms and uſages of countries and ſtates do alter, that it has been found impracticable to make any laws that could extend to all caſes: and our law itſelf does tacitly acknowlege its own imperfection in this caſe,

by allowing the CUSTOM of *merchants* to pass as a kind of law in cases of difficulty.

MERCHANT-*ship*. See SHIP.

MERCHANT-*law*. See LAW.

MERCHANT-*flatute*. See STATUTE.

MERCHANT, *tenant per flatute*. See TENANT.

MERCHENEAGE, *Merchenagium*, was the law of the people here called the Mercians. Camden, in his Britannia, fays, that in the year 1016, this kingdom was divided into three parts; whereof the Weft Saxons had one, governing it by the laws called Weft Saxonlage, which contained thefe nine fhires, viz. Kent, Suffex, Surrey, Berks, Hampfhire, Wilts, Somerfet, Dorfet, and Devon: the Danes had the fecond, containing fifteen fhires, i.e. York, Derby, Nottingham, Leicefter, Lincoln, Northampton, Bedford, Bucks, Hertford, Effex, Middlefex, Norfolk, Suffolk, Cambridge, and Huntingdon, which was governed by the laws called Danelage: and the third part was in poffeffion of the *Mercians*, whofe laws were called *Merchenlage*, and contained eight fhires, Gloucefter, Worcefter, Hereford, Warwick, Oxford, Chefter, Salop, Stafford, from which three, king William I. chofe the beft, and with other laws ordained them to be the laws of the kingdom. Camd. Brit. p. 94. See COMMON *Law*.

MERCHET. See MARCHET.

MERCURIAL, fomething that conſiſts of, or bears a relation to *mercury*, or quick-filver.

We fay alſo, a *mercurial* perſon, to denote a perſon of a briſk, volatile complexion; ſuch perſons being ſuppoſed by aſtrologers to be under the more immediate influence of the planet *Mercury*. We ſay, *mercurial* fumes, *mercurial* ſpirits, &c. with reference to the mineral *mercury*.

MERCURIAL *medicines*. See MEDICINALS.

MERCURIAL *phoſphorus*, *ſalivation*, *thermometer*. See the ſubſtantives.

MERCURIAL *ointments*, *frictions*, &c. See SALIVATION.

MERCURIAL *waters*. See WATER.

MERCURIALS, medicines compoſed, or prepared of MERCURY, or quick-ſilver.

The principal of the claſs of *mercurials* are, mercurius album, or white precipitate of mercury; ſweet and corroſive ſublimate of mercury; calomel; artificial cinnabar; turbith mineral; prince's powder; æthiops mineral, &c. See each under its proper article.

The medicinal efficacy of mercury depends on its extreme diviſibility, and the ſmoothneſs of its particles, and on their gravity or weight. By means of the firſt, it finds a paſſage into the inmoſt receſſes of the animal ſtructure, and, when properly guarded, does not exert itſelf till it comes into the remoteſt ſcenes of action; where moſt other medicines either do not arrive, or at leaſt not till their force is abated. This property it has in common with camphor.

By the latter, it is enabled to make ſtill more conſiderable alterations in the animal economy, by rendering the fluids thinner, and breaking open the ſecretory paſſages; and this effect it has in common with chalybeats.

It may be added, that the ſame property whereby it becomes ſo powerful a deobſtruent, indicates, that it is to be avoided in hectics, and all caſes where the conſtitution is drawn low by too profuſe evacuations; in regard *mercurials* tend to keep up or increaſe the exceſs of impetus in the fluids, and that over-capacity in the ſecretory orifices, wherein the defect of ſuch a conſtitution conſiſts to conſiſt.

MERCURIALIS, in *Botany*. See MERCURY.

MERCURIFICATION, in *Metallurgic Chemiſtry*, the obtaining the *mercury* from metallic minerals in its fluid form. For the effecting this, thoſe who have been engaged in theſe reſearches have propoſed three methods. The firſt is by means of a certain mercury, ſo prepared as to have a diſſolving power, by which it could take up the mercuries of metals in the ſame manner as water diſſolves ſalt from aſhes. The ſecond is by means of certain regenerating ſalts, ſuch as tal ammoniac, which are to detain the more earthy parts of metals, and leave their mercuries ſeparate or ſeparable from them by ſublimation or otherwiſe; and the third method is by means of a large lens or burning glaſs, in the focus whereof if any metal be expoſed, its mercurial part is ſaid to ſeparate and go off in fume, which when collected and condenſed, appears to be running mercury.

The firſt of theſe methods would be very eaſy, if the proper menſtrue were to be readily produced; the ſecond is extremely laborious, and requires much patience and reiteration. But the third ſeems eaſy enough, and practicable to advantage, when a glaſs of three or four feet in diameter is at hand, the ſky ſerene, and the ſun ſhines ſtrong.

For other proceſſes, the reader may conſult Junker's Conſpectus Chemiæ. But theſe mercurified metals, or their mercurial principle rendered ſenſible, are a kind of philoſophical mercury, which, although they reſemble ordinary mercury, are nevertheleſs ſaid, by perſons exerciſed in ſuch ſtudies, to differ from it conſiderably, by having a greater ſpecific gravity, by more effectually penetrating and diſſolving metals, by a ſtronger adheſion to them, and by a leſs volatility.

MERCURY, ☿, in *Aſtronomy*, the ſmalleſt of the inferior planets, and the neareſt to the ſun.

The mean diſtance of *Mercury* from the ſun is to that of our earth from the ſun as 387 to 1000: and his real diſtance from the ſun 36,843,468 miles. The inclination of its orbit, that is, the angle formed by the plane of its orbit with the plane of the ecliptic, is 6 degrees 54 minutes; its diameter to that of the earth, is nearly as 1 to 3, or 2660 miles; and therefore the globe of *Mercury* will be to that of the earth as 1 to 27. See DIAMETER, DISTANCE, EXCENTRICITY, and PLANET.

According to Sir Iſaac Newton, the heat and light of the ſun on the ſurface of *Mercury*, are almoſt ſeven times as intenſe as on the ſurface of the earth in the middle of ſummer: which, as he found by experiments made for that purpoſe by a thermometer, is ſufficient to make water boil. Such a degree of heat therefore muſt render *Mercury* uninhabitable to creatures of our conſtitution. And if bodies on its ſurface be not inflamed, and fet on fire, it muſt be becauſe their degree of denſity is proportionably greater than that of ſuch bodies is with us. The revolution of *Mercury* round the ſun, or his year, is performed in eighty-ſeven days, twenty-three hours; his diurnal revolution, or the length of his day, is not yet determined; nor is it certain whether he has ſuch a motion round his own axis or not.

What variety of weather or ſeaſons it may be liable to, we are ſtill alſo at a loſs to determine; as not knowing the inclination of his axis to the plane of his orbit. The force of gravity on the ſurface of *Mercury* is unknown. Its denſity, and conſequently the gravitation of bodies towards the centre, cannot be accurately determined; but no doubt it muſt exceed that of our earth, by reaſon of the exceſs of heat there.

Mercury changes its phaſes, like the moon, according to its ſeveral poſitions with regard to the ſun and earth; except only that he never appears quite full, becauſe his enlightened ſide is never turned directly towards us, but when he is ſo near the ſun as to be loſt to our ſight in his beams. And as his enlightened ſide is always towards the ſun, it is plain that he ſhines not by any light of his own; for if he did, he would conſtantly appear round.

The ſituation of this planet proves evidently, that the hypotheſis of Ptolemy is falſe: for *Mercury* is ſometimes obſerved betwixt the earth and ſun; and ſometimes beyond the ſun. But the earth is never found between *Mercury* and the ſun; which however muſt happen, if the ſpheres of all the planets encompaſſed the earth, as a centre, according to the Ptolemaic ſcheme.

The diameter of the ſun, viewed from *Mercury*, would appear almoſt three times as big as it appears on our earth; that planet being nearly thrice as near him as we are; and therefore the ſun's diſc would appear ſeven times as large as to us. *Mercury*'s greateſt diſtance from the ſun, with regard to us, never exceeds twenty-eight degrees (ſee ELONGATION); whence it is ſeldom viſible, being commonly either loſt in the ſun's light, or, when the moſt remote from the ſun, in the crepuſculums. The beſt obſervations of this planet are thoſe made when it is ſeen on the ſun's diſk; for, in its lower conjunction, it paſſes before the ſun like a little ſpot, eclipſing a ſmall part of his body, only obſervable with a teleſcope.

That node from which *Mercury* aſcends northward above the ecliptic is in the fourteenth degree of Taurus, the oppoſite in the fourteenth degree of Scorpio. The earth is in theſe points on the 6th of November, and 4th of May, new ſtyle; and when *Mercury* comes to either of his nodes at his inferior conjunction about theſe times, he will appear in this manner to paſs over the diſc of the ſun. But in all other parts of his orbit, his conjunctions are inviſible, becauſe he either goes above or below the ſun. The firſt obſervation of this kind was that of Gaſſendi, in November, 1631. Several ſubſequent obſervations of the like tranſits are collected in Du Hamel's Hiſt. of the Royal Acad. of Sciences, p. 470. ed. 2. Mr. Whiſton has given us an account of ſeveral periods at which *Mercury* may be ſeen on the ſun's diſc, viz. in 1782, Nov. 12th at 3ʰ 44ᵐ in the afternoon; in 1786, May 4th, at 6ʰ 57ᵐ in the forenoon; in 1789, Dec. 6th, at 3ʰ 55ᵐ in the afternoon; and in 1799, May 7th, at 2ʰ 34ᵐ in the afternoon. There will be ſeveral intermediate tranſits, but none of them viſible at London. See Dr. Halley's Account of the Tranſits of *Mercury* and Venus, in Phil. Tranſ. N° 193.

To an inhabitant of *Mercury*, the ſolar ſpots will appear

to traverse his disk sometimes in a right line from east to west, and sometimes elliptically. As the other five planets are above *Mercury*, their phenomena will be nearly the same there, as with us. Venus and the earth, when in opposition to the sun, will shine with full orbs, and afford a noble light to that planet.

MERCURY, *mercurialis*, in *Botany*, a genus of the *dioecia enneandria* class. Its characters are these: it has male and female flowers in different plants; the male flowers have a spreading empalement, cut into three concave segments, but have no petals; they have nine or twelve erect hairy stamina; the female flowers have no petals, but have two awl-shaped acute-pointed nectariums, to each of which there is a single broad germen, supporting two reflexed styles, which turn to a twin capsule, shaped like a scrotum, having two cells, each containing one roundish seed. Linnæus enumerates four, and Miller three species.

The species called French *mercury*, with branched stalks, and smooth glossy leaves, grows wild in gardens and dung-hills. It is of an emollient nature, and eaten in the manner of spinach, which, when cultivated in a garden, it greatly excels. If eaten largely, it opens the bowels. A cataplasm of the leaves is much recommended in pains of the limbs, in tumors, and even in ulcers, which it cleanses and disposes to heal. Poor people in country places use it as a cataplasm for the rheumatism, and even for the gout, with success. In the shops, it is chiefly kept as an ingredient in decoctions for clysters. There is another species, called cynocrambe, and dog's *mercury*, with rough leaves and unbranched stalks, which grows wild in woods and hedges: this, though more acceptable to the palate, as an oleraceous herb, than the foregoing, has lately been found to possess noxious qualities, and to act as a violent narcotic. See Phil. Transf. N° 203.

MERCURY, *English*, in *Botany*. See GOOSE *Foot*.

MERCURY, in *Chemistry*, and *Natural History*, denotes a fluid, MINERAL matter perfectly resembling silver in fusion.

Mercury is known under a great number of denominations: the common name among the ancients was *hydrargyrum*, q. d. water of silver. The moderns commonly call it *mercury*, from some supposed relation it bears to the planet of that name. In English it is popularly called *quick-silver*, from its appearance. Many of the chemists call it *Proteus*, from the variety of forms, colours, &c. it passes through in their preparations.

Naturalists are divided what class of fossils to range *mercury* under: some make it a metal; others a semi-metal; and others an imperfect metal.

Boerhaave observes, that it is very improperly called a *metal*, inasmuch as it has not all the characters of such a body; nor scarce any thing in common with the other metals, except weight, and similarity of parts: thus, for example, it is neither dissolvable by fire, nor malleable, nor fixed, in effect, it seems to constitute a peculiar class of fossils; and is rather the mother or basis of all metals than a metal itself.

However, it appears from the experiments of Professor Braun, at Peterborgh, recited under the article FREEZING, which ascertain the fixation of *mercury* by cold, that this, like other metals, is fluid or solid, according to the greater or less quantity of fire with which it is penetrated: and if we only see it in a fluid state, it is because it is so fusible that so small a degree of heat can keep it fluid, that even in the greatest natural colds, a sufficient quantity of heat always remains for that purpose. Besides, *mercury* agrees likewise with other metals, as their parts, when in fusion, attract one another, and run into globules, and, from a state of fluidity, pass into a solid state, not all at once, but successively, and vice versâ.

Perfect metals, according to M. Homberg, &c. are nothing but pure *mercury*, whose little particles are penetrated on all sides, and filled with the matter of light, which unites and binds them together into a mass, so that the parts of fluid *mercury*, which are supposed to be little solid globes, in their metallification are rendered rough and uneven, being pierced on all sides, and having their pores or perforations filled with the matter of light. By such means they lose their first conformation, and the polisure or smoothness of their surfaces, which is one of the principal causes of the fluidity of *mercury*.

The chemists make *mercury* one of their hypostatical principles: not, as M. Homberg observes, that it answers the character of a principle, which is that whose substance cannot be analysed, or reduced into matters more simple; but because the analysis has not yet been discovered; though it is possible it may hereafter, there being little doubt but that *mercury* is a compound. This is the more probable, because *mercury* may be destroyed; which never happens to simple bodies. The manner of destroying *mercury* is, first, by changing it into a perfect metal, by introducing a sufficient quantity of light within its substance; and then exposing this metal to a burning glass, where, in a little time, it evaporates almost wholly into smoke, leaving nothing behind but a light earthy dust.

MERCURY, *characters or properties of*, are, first, that of all bodies it is the heaviest, after gold and platina; and still the purer it is, the heavier: nay, some of the philosophers even hold, that *mercury*, well purged of all its sulphur, would be heavier than gold itself. The ordinary proportion between them is that of fourteen to nineteen. If any *mercury* be found to weigh more than according to this ratio, it may be safely concluded to have gold in it. See *Specific* GRAVITY.

The second character of *mercury* is, to be of all bodies the most fluid; that is, its parts separate, and recede from each other by the smallest force. Consequently, of all bodies it is that whose parts cohere the least, or are the least tenacious; and therefore of all others is the least ductile and malleable. The parts of water do not divide so readily as those of quick-silver; and the parts of oil much less: there is a certain tenacity even in the parts of spirit of wine, which resists separation; but there is scarce any cohesion at all in the parts of *mercury*. Nevertheless, the integrant parts of *mercury*, like those of melted metals, do really attract each other, and always acquire a convex or spherical form, when they touch bodies with which they have no tendency to unite.

The third property of *mercury*, which, indeed, depends on the second is, that of all bodies it is divisible into the minutest parts. Thus, being exposed to the fire, it resolves into a fume scarce perceivable to the eye; but, in whatever manner it be divided, it still retains its nature, and is the same specific fluid. For the vapours of distilled or volatilized *mercury*, received in water, or on moist leather, or the like, become pure *mercury*; and if *mercury* be mixed with other bodies, in order to fix it, it is easily separable from them again by fire, and reducible into pure *mercury* as before.

The fourth character is, to be extremely volatile, being convertible into a fume even by a sand-heat. In effect it does not sustain the fire long enough either to boil, or to ignite: though it must be added, if the fire be at first very gentle, and increase by easy degrees, it may be retained therein a pretty long time, and be fixed to at length as to become ignited in the crucible, as we learn from some very tedious experiments made at Paris.

That *mercury* is volatile, even in the temperature of the atmosphere, when its surface is exposed to a vacuum, has been long evident from observations on the barometer, in some of which, exposed in the sun, a perfect distillation is perpetually going on; the invisible mercurial vapour always rising on the warmer side of the tube, and then forming into globules, and running down on the opposite side, in the form of dense fluid *mercury*. But Dr. Priestley found, that this heavy substance is not less volatile, when confined by nitrific acid air, though pressed with the weight of the atmosphere, and that it is in some measure volatile, even when exposed to common air. Exp. and Obs. on Air, vol. v. sect. 23.

The gilders are but too well acquainted with the vapours of *mercury*, which frequently render them epileptic and paralytic, and sometimes salivate them; being of so penetrating a nature as to take away any scirrous tumors, though very apt to reach and destroy the noble parts.

It may here be observed that *mercury* seems to suffer no change from a heat that is not superior to that of boiling water. With a greater heat it is entirely dissipated in vapours, like other volatile bodies. But it undergoes no alteration by having been thus reduced into vapour; for if the evaporation be made in close vessels, that is, if the *mercury* be distilled, its vapours when condensed, will form the same *mercury* as before the operation. *Mercury* remains unchangeable by repeated distillations. Boerhaave distilled eighteen ounces of *mercury* five hundred times, without perceiving any other change than that its fluidity and specific gravity were a little increased, and that some grains of a fixed matter remained; which small changes were probably produced by a purification of the *mercury*, rather than by any real alteration of it. The vapours of *mercury*, like those of all other volatile bodies, if they cannot escape, or be condensed, cause violent explosions. By digestion in a strong heat, continued for several months, the surface of *mercury* is gradually changed into a reddish earthy powder, without any metallic lustre, which floats upon the surface of the fluid *mercury*, without incorporating with it. Thus any quantity of *mercury* may be entirely converted into a red powder. Boerhaave kept *mercury* in digestion for fifteen years, without observing any change, unless that upon its surface a little black powder had been formed, which by trituration was easily reducible into fluid *mercury*.

Dr. Prieſtley has ſhewn, by paſſing the electric exploſion over the ſurface of *mercury*, that this black matter conſiſts of *mercury* ſuperphlogiſticated; the phlogiſton coming from the electric matter when the exploſions are taken in common air, but chiefly from the vitriolic acid air, which abounds with it when they are taken in that air.

If *mercury* be expoſed to the focus of a burning glaſs on a piece of charcoal, on a tile, or in a coppel it is very ſoon wholly diſſipated in form of a thick ſmoke: but if precipitate per ſe be placed in the focus, it ſeems at firſt to melt and run, but immediately after is diſſipated in a thick ſmoke, leaving a ſmall quantity of an extremely fine powder upon the tile, in form of a ſhort down. This powder, on being continued in the focus, finally runs together into a yellowiſh glaſs; in ſeveral parts of which there may be diſtinguiſhed ſmall white, ſhining, metalline particles, which ſeem to be ſilver. If the precipitate per ſe be expoſed to the focus on a piece of charcoal, it is ſeen to melt and run into ſmall globules of pure *mercury*, which ſoon after begin to fume, and are diſſipated entirely. It appears, therefore, upon the whole, that there is in *mercury* an oil, as ſome have called it, or inflammable principle, which may be ſeparated by long digeſtion over a low fire; and that the matter diveſted of that, is no longer *mercury*, but a mere calx or red earth, which is properly the baſis of this metal: that this calx does not vitrify in the manner of the other calxes of the metals, being too volatile, and flying off eaſily in the fire; and, finally, that this oil of *mercury* is not different from the other oils, even thoſe of the vegetable kind, ſince common charcoal could ſupply its place by means of its oil or PHLOGISTON, and reſtore the calx to running *mercury* again. As to the ſmall remainder of earth, after the diſſipation of the calx of *mercury*, which run into glaſs with metalline ſpecks, it is much to be queſtioned whether it be not owing to ſome impurity in the *mercury*. Mem. Acad. Par. 1709.

The extreme denſity and gravity of *mercury* ſeem to prove that much of the earthy element, the eſſential properties of which are ſolidity and fixity, enters into its compoſition. On the other hand, its exceeding great volatility and fuſibility muſt proceed from the preſence of ſome other principle which is eminently volatile and fuſible. Is this principle PHLOGISTON? or is it Becher's mercurial earth? Is it the union of this inflammable principle, and of this mercurial earth? Theſe are objects worthy the curioſity of thoſe who have taſte and talents for the ſublimeſt reſearches in chemiſtry. Macquer.

The volatility of *mercury* may be diminiſhed by ſeveral methods, ſome of which we ſhall mention. 1. *Mercury* calcined by heat, called the precipitate per ſe, ſuſtains during ſome time a red heat, and by expoſure to the heat of a burning glaſs is vitrifiable. 2. Dr. Brandt relates a curious experiment, from which *mercury* appears capable of being ſo detained and fixed by digeſtion with gold, that a conſiderable part of it cannot be ſeparated from this metal by the moſt intenſe heat. 3. *Mercury* may be rendered conſiderably leſs volatile by being combined with vitriolic acid, but eſpecially with the vitriol of ſilver, or the ſalt formed by ſilver and vitriolic acid. This ſalt may be united with a conſiderable portion of *mercury*, with which it forms a concrete ſubſtance, fuſible by fire, but capable of ſuſtaining, according to Dr. Lewis, the greateſt heat that can be applied to glaſs veſſels, without diſſipation of the *mercury*. 4. Neumann ſays, that if *mercury* ſublimate be frequently ſublimed with ſal ammoniac, and each time the ſublimed matter mixed with the reſiduum, the whole becomes at laſt ſo fixed in the fire, that it cannot be any more ſublimed. *Mercury* expoſed to the vapour of melted lead, or thrown into boiling linſeed oil, loſes its fluidity, and becomes ſo ſolid, that it may be formed into toys and ſmall utenſils: this, indeed, properly ſpeaking, is only an apparent fixation of *mercury*, ſince all its fluidity is reſtored to it by a little heat; nevertheleſs this experiment proves, that ſome principle in theſe ſubſtances, probably their phlogiſton, is capable of acting ſenſibly on *mercury*.

The fifth property of *mercury*, is, that it eaſily enters, and intimately adheres to gold, leſs eaſily to other metals, with difficulty to copper, and ſcarce at all to iron.

Mercury may very well be alloyed and united with all metallic ſubſtances, excepting iron, arſenic, and the ſemimetal called nickel, in the following order: gold, ſilver, lead, tin, copper, zinc, and regulus of antimony.

The union of *mercury* with antimony is very difficult, but has been effected by Monſ. Malouin. See Hiſt. Acad. Science. 1740.

The ſame gentleman ſucceeded alſo in uniting *mercury* with tin and lead, ſo as to improve theſe metals in ſome reſpects, rendering them harder, whiter, and more ſonorous. Hiſt. Acad. ibid.

Biſmuth unites with it more intimately than any other metallic body, and remarkably promotes the union of lead with it: *mercury*, impregnated with a little biſmuth, was found to diſſolve conſiderable maſſes of lead in a heat no greater than that of the human body. Hence with theſe metals *mercury* has been frequently adulterated. This abuſe may be diſcovered by the *mercury* contracting a dull-coloured ſkin upon the ſurface, or ſtaining paper blackiſh, by its not running freely into round globules, but forming tears or vermicular ſtreaks by its leaving, on evaporating a little of it, a powdery matter, or coloured ſpot on the bottom of the veſſel; and by its producing a turbed milkineſs during its diſſolution in aqua fortis.

If *mercury* be diſſolved in aqua fortis, ſo that the ſolution be clear and total, and if, whilſt it is yet warm, ſome lead filings be poured in by degrees, the lead will be precipitated into a white powder, and the *mercury* reduced into a maſs of running quickſilver. Boyle's Works Abr. vol. i. p. 318.

All fat and oily matters, vegetable and animal, act upon *mercury*, ſo as to divide its parts and perfectly extinguiſh it. Mr. Plenck, of Vienna, having tried ſeveral ſubſtances, both animal and vegetable, for the extinction of *mercury*, found none that anſwered equally with gum arabic. He has therefore lately recommended a mixture of quickſilver and gum arabic, as preferable to all the mercurial preparations hitherto known; being in all caſes ſafe, rarely or never producing a ſalivation, and acting ſoon on the venereal virus. He directs one dram of purified quickſilver and two drams of the gum to be ground together in a ſtone mortar, adding by degrees half a ſpoonful of water, till the quickſilver diſappears, and the whole becomes a viſcid grey mucilage, in a ſhort time; half an ounce of ſyrup, and eight ounces of a ſimple water are then gradually added, and two ſpoonfuls of the mixture given every morning and evening; but the experience of other eminent phyſicians has not ſufficiently confirmed the ſuperior excellence of this mercurial preparation. See AMALGAMATION, ALLAY, and AFFINITY.

Indeed we have heard much among the adepts about making an amalgama with *mercury* and iron; but the experiment would never ſucceed with that ingenious chemiſt Dr. Boerhaave. If it poſſible there may be ſome way of binding thoſe two bodies together; and no doubt an amalgama might be made, if a large quantity of gold were added to the iron: but then, if the compound were beaten into duſt in water, the iron would waſh away, and the gold remain. On this account it is, that ſuch as have occaſion to handle quick-ſilver, always make choice of iron inſtruments for that purpoſe. We have known women, in a ſalivation, to have their ear-rings grow white and ſoft with the effluvia of the *mercury*; and hence the gilders, to lay gold on any other body, diſſolve it in hot *mercury*; which done, they apply the ſolution on the body to be gilt, ſuppoſe ſilver; then ſetting it over the coals, the *mercury* flies away, and leaves the gold adhering like a cruſt to the ſilver. Laſtly, rubbing this cruſt with lapis hæmatites, the ſilver is gilt.

The ſixth character is, that of all fluids, it is the coldeſt, and the hotteſt, ſuppoſing the circumſtances the ſame. Boerhaave ſhews, that fire is equally diffuſed through all bodies; and that there is in reality the ſame degree thereof in *mercury*, as in ſpirit of wine; and yet if you try with your finger, *mercury* in the cold is much colder, and over the ſame fire conſiderably hotter, than this ſpirit. This property depends on the great weight of *mercury*: for the heat and cold of all bodies is, *cæteris paribus*, as their weights. Now *mercury* being fourteen times heavier than water; if both of them be expoſed in a winter's night to the ſame cold, the mercury muſt be ſo much colder than water, as it is heavier. So alſo, if they be both applied to the ſame degree of heat, while the water becomes warm, the *mercury* will be hot enough to burn the hands.

The ſeventh property is, that it is diſſolvable by almoſt all acids, and unites itſelf with them at leaſt with all ſolible acids. This it is diſſolved in oil of vitriol, ſpirit of ſulphur per campanam, ſpirit of nitre, and aqua regia.

It is prepared with oil of vitriol, into turbith mineral; with ſpirit of ſulphur, into cinnabar; and with aqua regia, or ſpirit of ſea-ſalt, or ſal gemma, into corroſive ſublimate. Vitriolic acid in its original ſtate does not act, or but very weakly, upon *mercury*. Theſe two ſubſtances cannot be united together, unleſs the acid be very highly concentrated, and a very ſtrong heat applied; both which conditions concur in diſtillation. Nitrous acid diſſolves *mercury* very readily; and this ſolution preſents phenomena very ſimilar to thoſe of the ſolution of ſilver by the ſame acid. The acid ſhould be very pure, and the ſolution may be made without heat. Marine acid, when liquid does not act ſenſibly upon *mercury* in its ordinary ſtate,

even

even when assisted with a boiling heat. But when this acid, very concentrated and reduced into vapours, meets *mercury* also in vapours, these two bodies easily unite together, and even intimately. The several combinations of *mercury* with the vitriolic, nitrous, and marine acids, may be decomposed by all intermediate substances, which, having in general a stronger affinity with acids than metallic substances, decompose all metallic solutions by acids: these intermediate substances are absorbent earths, and alkaline salts, both fixed and volatile. They may be decomposed also, and particularly corrosive sublimate, by several metallic substances, such as tin, regulus of antimony, and copper.

Vinegar and vegetable acids have scarcely any action upon ordinary *mercury*, otherwise than by dividing it, with a little agitation, into very small globules; and hence we are furnished with a method of detecting the frauds of druggists, &c. who make a practice of sophisticating quick-silver with lead. Take a mortar, and rub the *mercury*, with vinegar therein; if the vinegar grow sweetish, it is a proof there is a mixture of lead; if copper have been mixed with the *mercury*, it will turn greenish, or bluish; if there be no adulteration, the *mercury* and vinegar will both remain as before.

However *mercury* may be dissolved in vegetable acids. This is done by reducing it to a calx by a long digestion. A scruple of this calx may be dissolved in an ounce of distilled vinegar, in a boiling heat. The solution being filtred and exposed to the cold, will in part be changed into fine crystals. This calx dissolves likewise in the juice of lemons, Rhenish wine, and other vegetable acids.

But a precipitate of *mercury* made from its solution in aqua fortis, by means of oil of tartar *per deliquium*, and well edulcorated by boiling water, is more easily dissolved in distilled vinegar. It may even be dissolved cold without digestion; and the acid of vinegar, as well as all other vegetable acids, are capable of contracting a very intimate union with *mercury*.

The eighth property is, that it is the most simple of all bodies, next after gold: accordingly, we find it the same in all its parts, so far as our observation goes. If a single grain of *mercury* be dissolved in spirit of nitre, a proportionable part of the grain will be distributed into every minute particle of the menstruum; and by diluting the whole with an ounce of aqua fygia, the whole grain of *mercury* will be revived. Had we the *mercury* of the philosophers, called also *vital mercury*, *mercury of metals*, &c. so much talked of, it is asserted, it would be still much more simple than gold: for from gold we can sometimes separate *mercury*, and sometimes sulphur; but, from pure *mercury*, nothing beside itself can be obtained.

Nevertheless *mercury* very powerfully attracts moisture from the air, and to this circumstance some have ascribed its fixation by cold, in the Peterburgh experiments; but this will not account for its malleability in that hardened state.

The ninth property of *mercury* is, not to be in any measure acrid in its native state; for it shews no acrimony to the taste, nor does it corrode any body: and if a carcase were to be buried in quick-silver, it might doubtless remain there without being any way hurt.

The extraordinary effects, however, it produces in the body, have given people a notion of its being acrid. But the case is, that, when received into the blood, it acts by its weight and velocity; whence it tears and destroys the solids, and thus occasions those great alterations, which lead the chemists into their mistakes.

In effect, all its medicinal operations are to be accounted for from the properties already enumerated.

Beside the numerous other phenomena attending this remarkable mineral, the light it gives when shaken in a glass tube, which proceeds from electricity, is not to be omitted. See *Barometrical* PHOSPHORUS.

If *mercury* be put into large exhausted tubes, and these afterwards rubbed to excite their electricity, it is observed that they give on all sides, rays of a bright and very lively light. See ELECTRICITY.

MERCURY, *mines of*. The chief are those of Hungary, Spain, Friuli, in the Venetian territories, and Peru. Considerable quantities are also brought from the East Indies. The greater part of our quick-silver is brought us from Friuli, where there are abundance of mines belonging to the emperor, though now mortgaged to the Dutch. It is found under three several forms: 1. In ruddy globes or clods, called *cinnabar*. 2. In hard stony globes, or a mineral substance of a saffron, and sometimes a blackish colour. 3. It is also found pure; for, upon opening holes in the beds of stones, &c. there sometimes gushes a vein or stream of pure *mercury*, called *virgin mercury*.

This last sort is most valued: Paracelsus and Basil Valentine prefer it far to any other sort, for chemical operations. Dr. Brown assures us, in his travels, that inquiring of one of the directors of the quick-silver mines, wherein the difference between this and common *mercury* consisted; he was answered, that virgin *mercury*, mixed and amalgamated with gold, renders the sulphur of the gold volatile; but this has been several times tried without success.

This *virgin mercury*, called *jungfrau* by the German miners, is used for that which discovers itself without the assistance of fire. This is sometimes seen in drops, globules, or large masses in the ore, or falls in drops from the crevices in the roof or walls of the mine, or finally, is found in large quantities in the hollows of the rocks. Its more common appearance is in small parcels, and often in single globules, scarce large enough to be discerned by the naked eye, lodged in great abundance in the pores of a soft solide stone, of a pale bluish colour, from which it is easily separated by pounding and washing. It is also found in some places lodged in the same manner, on some of the harder stones, and in various species of earths. These large collections of pure virgin quick-silver often discover themselves by bursting out in small streams in the mines of Friuli. They sometimes are spirted with a stream of it like a thread, which gradually increasing to the thickness of a packthread, continues to run three or four days, and discharges in that time a vast quantity of the quick-silver; if the miners can follow this spring to the head, they generally obtain a large quantity more; and often this sort of springing up of it leads them to very rich veins of the mine which they did not before know of. They give the same name of *jungfrau* or virgin quick-silver also to that *mercury* which has no need of fire for the separation, but is washed out of its ores by a sieve and large quantities of water, continually and forcibly running on it.

The ores of quick-silver often contain a large quantity of that mineral imbedded in them in this form, and often is mixed in other parts with sulphurs, as to be diffused into cinnabar; in this case a great deal is separated by this washing, which at the same time frees the ore from dirt, and renders it surer for the operation of the fire, by which a great deal more is then extracted.

However, though *mercury* be often found native, yet it is much more frequently found in the form of an ore; its particles being penetrated by, and intimately mixed with sulphur; and the concrete being by no means to be known for quick-silver to the naked eye, but being a red mass of a stony hardness, called *cinnabar*: and we are very sure that it is quick-silver penetrated by sulphur, that makes this ore, because we are not only able to separate quick-silver from it, but by a mixture of quick-silver and sulphur, we are able to make a red stony mass, perfectly the same with this. The cinnabar is of a different form and appearance, according to the quantity of sulphur it contains, being usually striated, sometimes with finer lines, and the quality of *mercury* in this is very great, the richest masses containing six parts of *mercury* to one of sulphur, and the poorer usually half. It is sometimes found in large and pure nodules, and sometimes in smaller particles, lodged in different earths and stones: these are sometimes few in number, and placed separately, so as to be of little value; but in other masses they are placed very thick in congeries, and are then separated by pounding and washing, and worked for *mercury*. Beside this pure ore of *mercury*, there is another much less rich, but which is worked in some places to considerable advantage: as the former is a mixture of *mercury* and sulphur alone, this is a mixture of these two, and of many other substances, and appears in form of a moderately hard stone, usually of a dusky orange colour, but not rarely of a greenish brown, and sometimes blackish. This has very little brightness, and nothing of the striated texture of the cinnabar.

Kircher, in his Mundus Subterraneus, gives a very terrifying description of the quick-silver mine of Friuli. It is remarkable, that the entrance into it is not high up in the hills, as is usually the case; but upon level ground, and in the streets of the town. This subjects the miners to great inconveniences from water, though they have excellent machines for draining the mines. The descent is by ladders near ninety fathoms deep. There are no damps in these mines, but the mischiefs arising from the *mercury* itself getting into the bodies of the workmen, are much greater and more general, though not so sudden, as the effects of the damps in our lead and coal mines, and such places. The elaboratory belonging to these mines has furnaces capable of working fifty retorts at a time. There are generally fifteen of these furnaces at work at once, so that eight hundred retorts are the usual number in constant use. The retorts stand in double rows on each side of the furnace, a row of thirteen below, and a row of twelve above.

Method

Method of procuring or separating MERCURY *from the ore or earth.*—They firſt grind the mineral glebe into powder; this done, they pour a great quantity of water upon it, ſtirring and working the whole briſkly about till the water become exceeding thick and turbid. This water having ſtood till it be ſettled, they pour it off, and ſupply its place with freſh, which they ſtir and work as before. This they repeat, and continue to do, till the water at length comes away perfectly clear; then, all remaining at the bottom of the veſſel is *mercury*, and other metalline matter.

To this *mercury*, &c. they add the ſcoriæ or filings of iron, putting the whole in large iron retorts, and ſo diſtilling it; by which means all the heterogeneous, metallic, and ſtony part, is ſeparated therefrom; and the *mercury* procured pure.

In ſome places where the ore is very rich, they only powder it and put it into long-necked earthen veſſels, which they ſtop with bundles of moſs: theſe they invert into other veſſels buried in the ground, and then making a fire about them, the *mercury* ſeparates and drains through the moſs into the under-pots.

As to the *mercury* in cinnabar, they do not find it worth while to diſtil, and get it out; cinnabar ſelling at too high a price alone.

The miſerable people, condemned or hired to work in theſe mines, all die in a little time. They are firſt affected with tremors, and proceed to ſalivation; then their teeth drop out; and they are ſeized with pains all over, eſpecially in their bones, which the *mercury* penetrates: and thus they die.

A common precaution they uſe, is to hold a piece of gold in the mouth, to imbibe the effluvia, and intercept their paſſage into the body. Dr. Pope tells us of one he ſaw in the mines of Friuli, who, in half a year's time, was ſo impregnated with the metal, that on putting a piece of braſs in his mouth, or even rubbing it in his fingers, it would turn white as ſilver.

In Spain, the ſmoking and exhaling of the mineral is performed with more care, and with an engine contrived for that purpoſe.

The manner of ſeparating *mercury* from its ore, when not ſulphureous, is this: take a pound of the ore beat to powder; this with the allayer muſt ſtand for one-tenth; put this into a glaſs retort coated half way to its neck, which muſt be long, and turned back with ſuch declivity, that a glaſs recipient may be applied perpendicularly to it. The retort muſt be of ſuch a ſize, that the belly of it may be filled nearly two thirds with the ore; and muſt be placed ſo that nothing of the fluid, adherent to the neck of it, may fall into the cavity of the belly, but that the whole may run forward into the recipient, which muſt be filled with cold water: this muſt be ſo placed as to receive the noſe of the retort about one half inch into the water. The joints need not be luted. Cramer's Art of Aſſaying, p. 350.

Let the retort be ſurrounded with burning coals, placed at a diſtance, leſt it burſt; by degrees bring the coals nearer, and at length cloſe to the retort; add freſh charcoal, and make it ſlightly red hot. When this fire has been continued an hour, take off the recipient, firſt ſtriking the neck of the retort to throw off the looſe drops that may hang there; and in the bottom of the water you will find the *mercury*. This proceſs may be alſo performed in a ſand heat; but the bottom of the retort muſt touch the bottom of the veſſel that contains the ſand, and that be made red hot. The *mercury* is to be ſeparated from the water by filtration.

The ore of the mine of Juan Cabelaca, in Peru, which is conſiderable, is of a whitiſh red, like bricks half-burnt; it is firſt broken, then expoſed to the fire, by ſpreading it on a layer of common earth, wherewith the grate of an earthen furnace is covered; under which is lighted a little fire of an herb, called by the Spaniards *ichu*; which is of that neceſſity in theſe works, that the cutting of it is prohibited for the ſpace of twenty leagues round. In proportion as the mineral heats, the *mercury* riſes volatilized into ſmoke; which ſmoke, finding no vent through the capital of the furnace, which is exactly luted, eſcapes through an hole made for that purpoſe, communicating with ſeveral earthen cucurbits fitted within one another. The water at the bottom of each cucurbit condenſing the ſmoke, the quick-ſilver precipitates, and is taken out, when the operation is over. In this proceſs, there are three things remarkable: the firſt, that the farther the cucurbits are from the furnace, the more they are filled with quick-ſilver; the ſecond, that they all grow ſo hot, that they would break, were they not ſprinkled from time to time with water; thirdly, that the workmen employed never hold it long, but become paralytic, and die hectic.

MERCURY, *the method of purifying*, from extraneous ſubſtances is important for the purpoſes of medicine and of the arts, and eſpecially for ſome nice chemical operations. *Mercury* may be cleanſed from duſt, by ſtraining it through ſhamoy leather; from greaſe, by waſhing it with an alkaline lixivium; from any alkaline matter, by vinegar; from lead or biſmuth, with which it is frequently adulterated, by diſtillation; from ſulphur, by mixing it with quick-lime or with filings of iron, and then diſtilling the mixture. Sometimes ſulphur is added to the *mercury*, and both are ſublimed together into cinnabar; then iron filings are added to this compound to abſorb the ſulphur, and the pure *mercury* is diſtilled off. Mr. Malouin recommends uniting the quick-ſilver with antimony inſtead of ſulphur. The beſt method of purifying *mercury* is by reducing it into Æthiops mineral, with which twice the quantity of quick-lime or filings of iron is to be mixed, and by diſtilling it from this mixture. In all diſtillations of *mercury*, the addition of filings of iron ſeems to render the *mercury* more fluid and bright. Its purity may be known, by obſerving that it does not ſoil clean white paper; that it has no pellicle on its ſurface; that when triturated with water, it does not ſoil the water; that when expoſed to fire, in an iron ſpoon or ladle, it does not crackle; and, laſtly, that it is perfectly and entirely ſoluble in pure ſpirit of nitre, without any depoſition. See BAROMETER.

MERCURY, *the uſes of*, are very conſiderable, as in gilding, making looking-glaſſes, in refining gold, &c. See each in its head.

But eſpecially in medicine, and particularly for the cure of the venereal diſeaſe, raiſing ſalivations, and on other occaſions.

This fluid, ſuppoſed by the Greeks to be poiſonous and corroſive, was introduced into medicine by the Arabians, as an ingredient in external applications, againſt different cutaneous maladies. The practice was followed by ſome phyſicians in Europe towards the end of the thirteenth century; but was not eſtabliſhed or looked upon in general to be ſafe, till about the beginning of the ſixteenth, when the venereal diſtemper, then lately received from America, was found to yield to mercurial applications alone: and now alſo the uſe of internal *mercury* began to be ventured on, in this and in other diſeaſes. Crude and fluid *mercury* taken internally, produces no effect on the body; becauſe the adheſion of its integrant parts to each other, hinders their diviſion and diſtribution, or ſolution, without which it cannot have any effect. In its crude ſtate, therefore, it does nothing but load the ſtomach and inteſtines. It falls downwards by its weight, and goes out of the body with the faeces, in the ſame ſtate in which it entered. Hence ſome have been induced to give a pound or more in violent conſtipations, in order to open obſtructions that had reſiſted the common methods of cure by purgatives, relaxants, and emollients. But the practice has been attended with no remarkable ſucceſs.

Dr. Dover, in his Phyſician's Legacy to his country, having recommended crude *mercury* or quick-ſilver as a moſt beneficial medicine for ſeveral diſeaſes, it had for ſome time a great run at London, which occaſioned the writing a great many pamphlets for and againſt it. Dr. Cheyne alſo greatly recommends this medicine in his treatiſe, intitled, the Rational Method of curing Diſeaſes.

The authors of the Medical Eſſays of Edinburgh aſſure us, that though ſome they knew had taken an ounce or two of crude *mercury* each morning for ſeveral weeks, yet they knew no inſtance of its increaſing any of the ſenſible evacuations; but they have been told, that ſome who uſed it thus, had paſſed ſome of it with their urine, and that the hands of others, taking this medicine, had tinged their ſnuff-boxes, &c.

But we have an account of the effects of crude *mercury* on a perſon who had the advice of his phyſician for the taking it, in a remarkable caſe recorded in the Philoſophical Tranſactions, about the time when Dr. Dover had brought it into ſuch general uſe; and as the effects of it, in this caſe, may ſerve to caution people as to the uſe of it, it may be proper to give the ſubſtance of it, which is this: a perſon had long been ſubject to great difficulty in going to ſtool, for which he at length took ſeveral ounces of crude *mercury* at different times, but without relief. Upon the opening of the abdomen there iſſued out a great quantity of wind, before the ſtomach or guts were wounded. The ſtomach was empty, and its inner coat violently inflamed. The ſmall guts were, in many places, fouled with a black powder, reſembling Æthiops mineral, and in ſeveral parts of them were found ſmall globules of quick-ſilver. The black powder was doubtleſs the quick-ſilver altered into a ſort of æthiops in the body. The colon was inflamed and diſtended, and contained ſix quarts of liquid excrement, among which was a great deal of crude *mercury*, and of the ſame black powder. This gut alſo was inflamed on the outſide, and had formed an abſceſs where

it adhered to the omentum; the other guts in contact with this part also shared this disorder. In the lower part of the colon the coats became schirrous, and the passage was very small. Some of the valves were also become schirrous, and obstructed the passage, and a small plum-stone was found buried in the villous coat of this intestine. This had also formed a small abscess, which discharged itself into the pelvis. What part of these symptoms was owing to the taking the quick-silver is easily seen, and such effects may be guarded against for the future, by observing the state of the patient before it is given. Phil. Trans. N° 442. p. 295.

But when *mercury* is much divided, so that its molecules cannot again unite and form fluid *mercury* by the interposition of proper substances, it operates with great power, and extends its action through the whole habit. In these forms, whether taken internally, or introduced into the blood from external applications, it seems to liquify all the juices of the body, and may be so managed as to promote excretion through all the emunctories. The salutary effects of mercurials have, in many cases, very little dependance on the quantity of sensible evacuation. Venereal maladies and chronical distempers proceeding from a viscidity of the humours and obstructions of the small vessels, are often successfully cured by mercurials taken in such doses as not to produce any remarkable discharge; especially if assisted by diaphoretics, and a warm diluting regimen. In this view, camphor, and the resin or extract of guaiacum, are frequently joined to the *mercury*, and to the more active preparations, a little opium: which not only promotes the diaphoresis, but prevents the *mercury* from irritating the first passages, and running off by the grosser emunctories. Mercurials are always pernicious in the true scurvy, and in constitutions inclined to this disease, whose humours are disposed to a putrescent state; and a long continued use of *mercury* colliquates the whole mass of blood, and tends to weaken the nerves, so as to bring on tremors and paralyses. Mercurials are destructive to insects, perhaps of every kind: they are sometimes given internally against worms, and Van Helmont says, that water in which *mercury* has lain some time, though infused, will destroy worms; and Mr. Boyle seems to recommend it as an innocent and useful cosmetic. Works Abr. vol. iii. p. 345.

Mercurials are also applied externally, in unguents, for destroying cutaneous animalcula. See Itch. *Mercury* has of late been recommended as an effectual antidote against the poison of the mad dog. See Madness.

Mercury dissolved by rubbing it strongly with any chemical oil, or with Venice turpentine, has been given to the quantity of a scruple, half a dram, or two scruples in a day. Such pills keep some people's bellies open, others they purge, and a gentle ptyalism has sometimes been occasioned, nay, a high salivation has been raised by them. See Medic. Ess. Edinb.

Chemists having observed that some simple preparations of antimony and *mercury* had surprising effects in the cure of obstinate distempers, employed their art to change these Herculean medicines into various shapes, to separate their noxious and useless parts, and to combine their active principles. To these labours are owing the butter and cinnabar of antimony, *mercurius vitæ*, bezoard mineral, solar, lunar, jovial, and several other preparations, on which the most exorbitant encomiums have been lavished. But with all this care, many of these remained inactive, and others incorrigible, and unfit for use. However, it is certain that these two minerals, properly combined, have wonderful effects. We have, in the Medical Essays of Edinburgh, a preparation of Dr. Plummer, which is much recommended from the experience of its effects. See Plummer's *Æthiops*.

Mercury is often used in anatomical preparations, especially for such parts that do not easily retain air, as the lungs, or spleen, and glans penis. See Monro, in Med. Ess. Edinb. vol. iii. art. 16. But it is to be observed, that the quick-silver does considerable damage to the small cells of the lungs and glans.

Mercury is divided with different materials for internal use, and given as an alterative and as an alexipharmic, from two or three grains to eight or more. Half a dram of quick-silver is ground with two scruples and a half of prepared crabs eyes, and called *alkalizate mercury*, or with half a dram of brown sugar-candy, and two drops of oil of juniper berries, which last ingredient renders the union of the *mercury* with the sugar more perfect, and called *mercurius saccharatus*. See Pills.

Mercury, *the preparations of*, are very various; this metal making one of the most considerable articles in the chemical pharmacy. The most common preparations now in use, are, *Æthiops mineral*, æthiops cum igne, differing from the other only in the more intimate coalition of the *mercury* and sulphur, by melting the latter over a gentle fire, and gradually stirring into it the quick-silver; care being taken to cover the vessel when it seems disposed to catch flame: *factitious* cinnabar; *corrosive sublimate of* mercury, *mercurius dulcis*, *calcined* mercury, or *precipitate per se*, *white precipitate of* mercury, red precipitate or red corrosive *mercury*, *coralline* mercury, and turbith *mineral*.

Mercury, *calcined*, *mercurius calcinatus*, a new and more expressive name for the preparation of *mercury*, commonly called *precipitate per se*. It is made by setting purified quick-silver for several months in a sand heat, in a glass vessel with a broad bottom, and opening it to the air by a small hole, till it is reduced to a red powder.

The quick-silver must have a communication with the external air, as is necessary to the calcining of all the metals. This opening is best made, not as in the common bolt-heads, but at the lower end of a flask, going into the body of the glass; that if the quick-silver rise with the heat, it may not, by ascending into the flask, be removed out of the heat that is to calcine it.

A greater heat, sufficient to make the *mercury* freely distil, not only does not promote the calcination, but revives such part, as has been already calcined into *mercury* again. See Mercury *supra*. This red powder has been by some greatly esteemed in venereal cases, as the most effectual and certain of the mercurials. Mindabin's pills are supposed to be of this kind: but as it is disposed to occasion gripes, it has been usual to join with it a small quantity of opium, and some warm aromatic material. The dose is from half a grain to two grains; five or six grains are said to vomit and purge violently.

Mercury, *corralline*, *mercurius corallinus*, the name given in the London Dispensatory to a preparation of *mercury*, commonly known by the name of Arcanum *corallinum*. It is prepared in this manner: pour upon the red corrosive *mercury*, commonly called *red precipitate*, thrice its weight of rectified spirit of wine, digest them together in a gentle heat for two or three days, often shaking the phial, then set fire to the spirit, and continue stirring the powder till the spirit is burnt away.

This operation proceeds upon the principle of spirit of wine dulcifying acid spirits.

This medicine, notwithstanding this preparation, is a very rough one, operating, generally, in doses of a few grains, both upwards and downwards.

Mercury, *incalescent*. See Incalescent.

Mercury, *oil of*, the name given by the chemists to a preparation of *mercury* in a fluid form, by means of a strong acid. The preparation is this: calcine *mercury* with oil of vitriol to a dry (mowy) calx; suffer it to cool, then put it into a glass, and pour upon it an equal quantity of oil of vitriol; let this boil away almost to a dryness, carefully avoiding the poisonous fumes; then increase the fire, and by degrees reduce it to a dryness again; which is, in this state, a very difficult and tedious task. When the powder is dry, put the same quantity of oil of vitriol again to it, and proceed as before: at length it will scarce dry by means of ever so long or strong a fire, but only cease flowing freely, and become somewhat rigid like a fixed oil. It is then highly sharp, caustic, and not to be touched, like the *ignis gehennæ* of Paracelsus. By this means the *mercury* is so fixed with the oil of vitriol, as not to be evaporated, or fly off, by the action of a very violent fire.

By this process we see the method of impregnating, saturating, and incrusting metals by acids to any degree, and also of fixing, in a great degree, volatile *mercury* by them; but no metal is hence to be expected, for in whatever manner *mercury* is fixed with acids, it is always recoverable again in its pristine state, by grinding it with twice its weight of iron filings, and distilling in a glass retort, with the greatest degree of sand heat. Boerhaave.

Mercury, *ointment of*. See Unguent.

Mercury, *pills of*. See Pills.

Mercury, *plaster of*. See Emplastrum and Plaster.

Mercury, *red precipitate of*, is prepared by inspissating the solution of *mercury* in aqua fortis, over a gentle fire; when there remains a white mass highly caustic called *calx of mercury*: this calx is then calcined with a gradual heat, and becomes first brown, then yellow, and at length, on increasing the heat, of a deep red colour. It is called *red precipitate*, but improperly, for it is not a precipitate. If the aqua fortis used for the dissolution has been previously drawn over from a small proportion, on the one hundred and twenty-eighth part of its own weight, of sea-salt, the red mass is supposed more readily to assume the sparkling appearance which is looked upon as the characteristic of its goodness. This preparation is employed, as an escharotic, and mixed with ointments and cerates, as a digestive; in which intention, Mr. Sharp observes, that it is very effectual.

Mercury, *white precipitate of*, Mercurius *precipitatus albus*.

alba. This is compounded of crude *mercury* driven over from sea-salt in a retort, or revived from common cinnabar, and dissolved in aqua fortis; then a brine prepared of spring-water and sea-salt is filtred through a cap-paper, and the solution of *mercury* dropped gradually into this brine; whence there is a white powder precipitated, which is to be washed from all its acrimony with some simple distilled water, or warm spring-water, and afterwards dried.

This is the common precipitate of the shops, usually called *white precipitate*. Its operation is mostly by stool, sometimes by vomit; and it will salivate, if ordered accordingly. It is recommended by Boerhaave as one of the best of the mercurials, and said, in doses of three grains, to purge and vomit gently. It appears, however, too corrosive for internal use; and it is indeed corrosive to such a degree, as to be employed by the farriers for an escharotic. Spirit of sal ammoniac, or other volatile alkalies, drops into a filtered solution of sublimate, absorb a part of the acid, and the *mercury*, retaining so little as to be insoluble, renders the liquor milky, and subsides, on standing, in form of a fine white powder, which washed by repeated affusions of hot water, becomes insipid, and is the *white mercurial precipitate*, of the Edinburgh Pharmacopœia. If an equal weight of crude sal ammoniac be dissolved along with the sublimate, fixed alkalis added to this solution, extricate the volatile alkali of the sal ammoniac, and the precipitate, which is that of the London Pharmacopœia, proves the same, as if the volatile alkali alone had been added in its pure state. This *white precipitate* is frequently mixed with pomatums for the itch, and other foulnesses of the skin; for which purpose, it is necessary at the same time to keep the body laxative, and to take something inwardly to take hold of the mercurial principles, and prevent their raising salivation, which they may otherwise do.

MERCURY, *corrosive sublimate of*, MERCURIUS *sublimatus corrosivus*, is a compound of forty parts of quick-silver, rubbed with one part or more of sublimate already made, till it is divided into minute grains, then ground with twenty-eight parts of nitre, then with thirty-three of common salt, and afterwards, for a little time longer, with three-fifths of calcined green vitriol: the mixture is then put into a matrass, and that set in a furnace with a sand-heat, under which a fire being kept to its greatest height for twelve or fifteen hours, the *mercury* will be sublimed, and stick to the top of the vessel.

Mr. Boulduc describes an easy manner of making corrosive sublimate. He pours equal quantities of quick-silver and dephlegmated oil of vitriol into a retort, then draws off part of the acid, which does not incorporate with the quick-silver; the fire is continued till the white mass of dissolved *mercury* is dry, when he speedily mixes it with equal parts of dried sea-salt, and sublimes it in the common way.

If the mass obtained by inspissating a solution of *mercury* in aqua fortis, be powdered and mixed with equal its weight of dried sea-salt, and the mixture put into a matrass, of which it may fill nearly one half, and set in a sand-heat gradually increased, almost all the *mercury* will be saturated with the marine acid, and form with it a saline compound, which being sublimed, concretes into a white mass called *corrosive sublimate*. If the vitriolic acid be used instead of the nitrous, the event will be the same: in the one case a *sal cathareticus* will be formed; in the other a *nitrum calcinans*.

This sublimate is a violent escharotic, and eats away proud flesh; half a dram of it dissolved in a pint of lime-water, turns it yellow, which is then called *phagedenic* water; it is used to wash ulcers, and tetterous eruptions. A stronger solution, made by boiling the same quantity of powdered sublimate, with equal its weight of alum, in a pint of common water, till half the liquor is wasted, is the ALUMINOUS *water* applied to the same purpose. Small doses of this corrosive preparation, properly diluted, have been ventured on internally. Boerhaave relates, that if a grain be dissolved in an ounce of water, and a dram of this solution softened with syrup of violets, taken twice or thrice a day, it will perform wonders in many distempers reputed incurable. Van Swieten brought it into more general use, for the cure of venereal maladies: he dissolves a grain of the sublimate in two ounces of proof spirit, but rectified spirit dissolves it more perfectly, and gives of this solution from one to two spoonfuls twice a day, continuing the medicine so long as any of the symptoms remain, with a low diet, and plentiful dilution. There are many instances in the London Medical Obs. and Inq. of the success of this method.

MERCURY, *sweet sublimate of*. MERCURIUS *sublimatus dulcis*, or *aquila alba*, is a composition of the preceding corrosive sublimate with crude *mercury*, ground together till no *mercury* appear, and then put into a bolt-head, well stopped, and set in a sand-heat, with a gentle fire, for the space of two hours; which heat is to be then increased for three hours longer, and, lastly, made very strong, for an hour more. When this is cold, the glass is broken, and the sublimate separated from the light flowers at top, and the dust at bottom. This is then powdered afresh, and the operation repeated in the same manner three times. If it be farther repeated, to a fixth time, it is called CALOMEL.

The college of Edinburgh directs the sublimation to be repeated three or four times; that of London, six times. *Mercurius dulcis* in large doses, with cinnabar of antimony, is recommended in nervous diseases, palsy, hemiplegia, epilepsy, and apoplexy. Med. Ess. Edinb.

Mr. Dictericus gives us these rules for knowing whether sublimate is sufficiently edulcorated in making *mercurius dulcis*. If after rubbing the *mercury* on gold, the gold becomes only pale, and not white, the *mercury* is dulcified enough; or if sweet *mercury* becomes black when mixed with lime-water, it is fit for use; but if either the gold becomes white, or the *mercury* is of a brown or yellow colour, after mixing with lime-water, it is not sufficiently dulcified. Commerc. Norem. 1737, hebd. 29. sect. 3.

Mercurius dulcis appears to be the best and safest of the mercurial preparations that can be taken in a solid form: as a salagogue, five, ten, and sometimes fifteen grains, made into a bolus or pills, are repeated every night or oftener, till the ptyalism begins: as an alterative, it is given from one to two or three grains. It generally answers best in small doses, which may be repeated with due caution, every evening, for a considerable time without inconvenience.

MERCURY, *emetic yellow*, *mercurius emeticus flavus*, a name given in the late London Dispensatory to the mercurial preparation commonly known by the name of TURBITH *mineral*.

MERCURY, *fixing of*. The supposition of a sympathy between *mercury* and gold has been the great basis of the attempts of the alchemists of all times, toward the making gold of it. But if they mean that the common *mercury* has this sympathy with gold, the contrary is proved by that remarkable process, in which it appears that *mercury* will incalesce with that metal. If they mean that *mercury* which they call the seed of metals, it is hard to offer any thing in argument against it, this being a sort of ideal subsistance which nobody has yet seen. It is much disputed by the alchemists, whether there be or be not any such thing as *mercury* that will heat or incalesce with gold, or produce a sensible heat in the mass, on being only simply mixed with that metal reduced to fine parts. It has been said by some, that those *mercuries* which they call *mercuries corporum*, that is, such as have been extracted from the complete metals by certain processes, which they keep as invisable secrets, will incalesce on the mixture with gold; and on this they build their processes. But the negative part of the question is more generally maintained, the famous *mercuries* of metals being held as non-entities with them; and even the searchers after transmutation of metals have in general acknowledged, that they themselves never saw any such incalescence of *mercury* with gold, though they had heard others speak of it as a thing they had seen. A *mercury*, however, was some years ago produced before the Royal Society, which in the hands of the president himself, on the fairest trial, did incalesce with that metal. Phil. Trans. N° 122.

Among the several methods recommended for the fixing this fluid metal into solid silver, oil of talc, and oil of the human fæces, are the most strongly affirmed to be the infallible mediums. The first of these which has been so much misunderstood, by reason of its name, as to be searched for in the stone talc, is truly an oil prepared from the flowers of zink. See *Oil of* TALC.

The other is required to be clear and colourless as water, and without any ill smell. These were qualities so difficultly to be found in an oil of that fœtid matter, that both the one and the other of these oils were looked upon by many as impracticable processes. But after the first had been made by two or three chemists, Mr. Homberg at length hit upon the last, but without finding any the least tendency to such an effect in it, or any change at all produced by it on *mercury*, after ever so long digestion, or ever so many processes. Ment. Acad. Par. 1711. See PHILOSOPHER'S *Stone*.

MERCURY, *animated*, is quick-silver impregnated with some subtile and spirituous particles; so as to render it capable of growing hot when mingled with gold.

MERCURY, or MERCURY *of bodies*, is also used by chemists to denote the thirds of the principles or elements of natural bodies, called also spirit.

In this sense, *mercury* is defined the most subtile, light, volatile,

volatile, penetrating, and active part of all bodies. See SPIRIT.

MERCURY *of life*, *mercurius vitæ*, may according to Mr. Boyle, be moderated in its evacuating quality, by continually ſtirring it in a flat glazed earthen veſſel, over a fire, till it emits no fumes, and turns of a grey colour; and he thinks this is the *mercurius vitæ purgans* ſo often mentioned by Riverius. Boyle, Works abr. vol. i. p. 74. Mr. Godfrey obſerves that what is called *mercurius vitæ*, prepared of ſublimate *mercury* and antimony, has no *mercury* in it, but is the reguline part of the antimony, with the acid of the ſublimate; and what remains is the *mercury* formed into cinnabar by the ſulphur of the antimony. See ALGAROT.

MERCURY *of metals*, or of the *philoſophers*, is a pure fluid ſubſtance in form of common running *mercury*, ſaid to be found in all *mercury*, and capable of being extracted from the ſame.

The notion of *mercury* of metals is founded on the common ſyſtem of the chemiſts, that *mercury* or quickſilver is the baſis or matter of all metals; and that metals are only *mercury* fixed by a certain ſulphur.

Mr. Boyle aſſures us, he had a way of drawing a true running *mercury*, or quickſilver, from antimony.

MERCURY alſo ſerves as a title for books, and papers of news; ſo called from the heathen deity Mercury, ſuppoſed the meſſenger of the gods.

Thus we have monthly *mercuries*; and the French have a gallant *mercury*, &c.

In the like ſenſe, *mercury* is alſo figuratively applied to perſons who make it their buſineſs to collect news, or to run about and diſtribute it.

MERCURY, in *Heraldry*, denotes the purple colour in the coats of ſovereign princes.

MERCURY, in *Mythology*, the ſon of Jupiter and Maia. He was the god of merchandize, and therefore was ſometimes painted with a wand in his left hand, and a bag of money in his right. He was alſo the god of eloquence, and the meſſenger of the gods; he is pictured therefore with a herald's ſtaff in his hand, entwined with two ſnakes; wings on his feet, to ſhew his ſpeed; and a broad-brimmed beaver with wings. He had a general power delegated to him, by Jupiter, of conducting the ſouls of men to their proper place, after their parting from the body; and reconducting them to our world again, when there was any particular occaſion for it. He was, moreover, the god of all gainful arts; whence the proverb, *ξυρὸς ἰχθὺς*, i. e. *commune lucrum*; eſpecially of things found by chance: the inventor of the lyre, and of the exerciſe of wreſtling. He was the patron of thieves, having himſelf been expert that way; and the guide of travellers, for which reaſon he had ſtatues four ſquare ſet up to him in croſs roads. See TERMINUS. There are ſeveral marks whereby *Mercury* may be known; among which we may reckon the ſightneſs and agility of his perſon as the chief; but the moſt remarkable of his diſtinguiſhing attributes are his petaſus, or winged cap; the talaria, or wings to his feet; and his wand, with two ſerpents about it, which they call his caduceus. Sometimes he is alſo repreſented with the chlamys, faſtened over his ſhoulders on his breaſt, and floating behind him in the air. He is likewiſe diſtinguiſhed by his ſword, with which he killed Argus, called Harpe. As the make of *Mercury* ſeems to be all intended for lightneſs and diſpatch, the ancients might borrow this idea of him from his planetary character: thus Lucan. Pharſal. i. v. 663. in ſpeaking of *Mercury*, as the guiding intelligence of a planet, marks the ſwiftneſs of his motion.

MERCURY is ſometimes alſo uſed for the Torricellian experiment, or BAROMETER.

Though *mercury* be not ordinarily ſuſtained in a tube above the height of twenty-eight or twenty-nine inches; yet M. Huygens has found, that *mercury* well purged, and in a cloſe ſtill place, will be ſuſtained to the height of ſeventy-two inches. See TORRICELLIAN.

MERCY, in *Law*. See MISERICORDIA.

MERDESENGI, in the *Materia Medica of the Arabians*, a name given by Serapio to litharge. Avicenna calls this ſubſtance MARDAC, and it has been erroneouſly ſuppoſed from this, that *mardac* and *mardeſengi* were not the ſame ſubſtance; but this is a falſe conjecture.

MERDIVORÆ, from *merda*, *dung*, and *voro*, *I devour*, the *dung-eaters*, in *Natural Hiſtory*, the name given by authors to ſeveral flies which feed on excrements of different animals. Of theſe there are three kinds very common among us: 1. the COPROPHAGUS, which is of a dun colour, with a reddiſh head, and a white ſtreak along the middle of it; 2. the red *dung-fly*, which has ſilvery wings, a red body, and black ſhoulders; and, 3. the green one, which is of a very glittering hue, and has ſilvery wings.

MERGANSER, in *Ornithology*, the name of a large water-fowl, called in Engliſh, the *gooſander*, and by ſome authors, the *burle*.

This is the MERGUS *merganſer* in the Linnæan ſyſtem: the bill of the male of this ſpecies is about three inches long, narrow, and finely ſerrated; the colour of the bill as well as of the irides is red; the head is large, and the feathers on the hind part long and looſe; the colour black, finely gloſſed with green; the upper part of the neck the ſame; the lower part and under ſide of the body of a fine pale yellow; the upper part of the back and inner ſcapulars are black; the lower part of the back and tail are aſh-coloured; the tail conſiſts of eighteen feathers; the greater quill-feathers are black, the leſſer white, ſome of which are edged with black; the coverts at the ſetting on of the wings are black; the reſt white; and the legs of a deep orange colour. The female of this ſpecies is called DUNDIVER. Theſe birds frequent our rivers and freſh waters, eſpecially in hard winters; they are never ſeen in the ſouthern parts of Great Britain during ſummer, when they retire far north to breed. They are great divers, and live on fiſh. Their fleſh is extremely rank, and ſcarce eatable. Pennant.

MERETRIX, among the Romans. The *meretrices* were the better ſort of courtezans, and differed much from the *proſtibulæ*, or common proſtitutes, who had bills or inſcriptions, *tituli*, over their doors, and were ready at all times to entertain their cuſtomers; whereas the *meretrices* entertained none but at night.

The *meretrices* were diſtinguiſhed from the matrons by their dreſs, being obliged to wear the *toga* and ſhort tunics, like thoſe of the men; whereas the matrons wore the *ſtola*, which was a garment that reached down to their feet, as did likewiſe their *palla*, or outer robe.

MERGEN, a word uſed by ſome of the chemical writers to expreſs CORAL.

MERGER, in *Law*, is where a leſſer eſtate in lands, &c. is drowned in the greater; as, if the fee comes to tenant for years or life, the particular eſtate is *merged* in the fee: but an eſtate tail cannot be *merged* in an eſtate fee; for no eſtate in tail can be extinct by the acceſſion of a greater eſtate to it. If a leſſor, who had the fee, marries with the leſſee for years, this is no *merger*, becauſe he hath the inheritance in his own, and the leaſe in right of his wife. And where a man hath a term in his own right, and the inheritance deſcends to his wife, ſo that he hath a freehold in her right, the term is not *merged* or drowned.

MERGUS, in the Linnæan ſyſtem of *Ornithology*, the name of a diſtinct genus of birds, of the order of the *anſeres*. The diſtinguiſhing characteriſtic of this genus is, that the beak is ſomewhat cylindric, and has a crooked point. The characters of this genus, according to Mr. Ray, are theſe: the feet are webbed, the three fore-toes being connected by a membrane, but the hinder-toe is left looſe; the beak is narrow, hooked at the end, and ſerrated.

Of this genus are the MERGANSER, the *mergus cucullatus*, with a globoſe creſt, white on the ſides, with a black margin, the body blackiſh on the upper part and whitiſh on the lower; the feet and beak are black: this is alſo called *anas criſtata*, and bird of the wind: it is found in America: the *albellus*, or Aldrovand, called *mergus ſerratus major*, the greater creſted diver, and *mergus Rhenanus*, the diver of the Rhine, and commonly known in England by the name of the SMEW: the head is adorned with a long creſt, white above and black beneath; the forehead is marked with a large ovil black ſpot; the body is white, the back and temples black, and the wings are variegated with black and white; it feeds on fiſh, and is very common on our coaſts: the *mergus ſerrator*, or *ſerrulo* of the Venetians: the *mergus coſtor*, with an aſh-coloured creſt, the lower part of the body ſerruginous, white throat, and beak and feet blackiſh: and the *mergus minutus*, with the head of a light grey colour, and an oval black ſpot from beyond the eyes to the bill, and a white ſpot under the eye. Ray makes this to be the female of the *albellus*, which it greatly reſembles, though it is diſtinguiſhed by the name of *lough diver*.

MERGUS *cirratus minor*, in *Ornithology*, a name by which Geſner calls the *capo negro*, a ſpecies of duck, called in Engliſh the *tufted* DUCK.

MERIDIAN, in *Aſtronomy*, a great circle of the ſphere, paſſing through the zenith, nadir, and poles of the world, croſſing the equinoctial at right angles, and dividing the ſphere into two hemiſpheres, the one eaſtern and the other weſtern.

Or, the *meridian* is a vertical circle, as A Z B N (*Tab. Aſtron. fig.* 6.) paſſing through the poles of the world, P and Q.

It is called *meridian*, from the Latin *meridies*, *noon*, or *mid-day*, becauſe when the ſun is in this circle, it is noon in thoſe places ſituate under it.

MERIDIAN, in *Geography*, is a great circle, as P A Q D (*Tab. Geography, fig.* 7.) paſſing through the poles of the

earth P and Q; and any given place at Z. So that the plane of the terreſtrial *meridian* is in the plane of the celeſtial one.

Hence, 1. as the *meridian* inveſts the whole earth, there are ſeveral places ſituated under the ſame *meridian*. And 2. as it is noon-tide whenever the centre of the ſun is in the *meridian* of the heavens; and as the *meridian* of the earth is in the plane of the former; it follows, that it is noon at the ſame time, in all places ſituate under the ſame *meridian*. 3. There are as many *meridians* on the earth, as there are points conceived in the equator. In effect, the *meridians* always change, as you change the longitude of the place; and may be ſaid to be infinite; each reſpective place from eaſt to weſt having its reſpective *meridian*.

MERIDIAN, *firſt*, is that from which the reſt are accounted, reckoning from weſt to eaſt. The firſt *meridian* is the beginning of longitude.

The fixing of the firſt *meridian* is a matter merely arbitrary; and hence different perſons, nations, and ages, have fixed it differently; whence ſome confuſion has ariſen in geography. The rule among the ancients was, to make it paſs through the place fartheſt to the weſt that was known. But the moderns knowing, that there is no ſuch place in the earth as can be eſteemed the moſt weſterly, the way of computing the longitudes of places from one fixed point is much laid aſide.

Ptolemy aſſumed the *meridian* that paſſes through the fartheſt of the Canary Iſlands as his firſt *meridian*; that being the moſt weſtern place of the world then known. After him, as more countries were diſcovered in that quarter, the firſt *meridian* was removed farther off. The Arabian geographers chooſe to fix the firſt *meridian* upon the utmoſt ſhore of the weſtern ocean. Some fixed it to the iſland of St. Nicholas near Cape Verd; Hondius to the iſle of St. James; others to the iſland of Del Corvo, one of the Azores; becauſe on that iſland the magnetic needle, at that time, pointed directly north, without any variation; and it was not then known that the variation of the needle is itſelf ſubject to variation. The lateſt geographers, particularly the Dutch, have pitched on the Pike of Teneriffe; others on the iſle of Palm, another of the Canaries; and, laſtly, the French, by command of their king, on the iſland of Fero, another of the Canaries.

But, without much regard to any of theſe rules, our geographers and map-makers frequently aſſume the *meridian* of the place where they live, or the capital of their country for a firſt *meridian*; and thence reckon the longitudes of their places.

The aſtronomers in their calculations uſually chooſe the *meridian* of the place where their obſervations are made, for their firſt *meridian*; as Ptolemy at Alexandria; Tycho Brahe at Uranibourg; Riccioli at Bologna; Mr. Flamſteed at the royal obſervatory at Greenwich; and the French at the obſervatory at Paris.

In the Philoſophical Tranſactions, there is a ſuggeſtion, that the *meridians* vary in time. This ſeems very probable, from the old *meridian line* in the church of St. Petronio at Bologna, which is found to vary no leſs than eight degrees from the true *meridian* of the place at this time; and from that of Tycho at Uranibourg, which M. Picart obſerves, varies eighteen minutes from the modern *meridian*. If there be any thing of truth in this hint, Dr. Wallis ſays, the change muſt ariſe from a change of the terreſtrial poles (here on earth, of the earth's diurnal motion), not of their pointing to this or that of the fixed ſtars: for if the poles of the diurnal motion remain fixed to the ſame place on the earth, the *meridians*, which paſs through theſe poles, muſt remain the ſame.

But the notion of the changes of the *meridian* ſeems overthrown by an obſervation of M. Chazelles, of the French Academy of Sciences, who, when in Egypt, found that the four ſides of a pyramid built three thouſand years ago ſtill looked very exactly to the four cardinal points. A poſition which can never be looked upon as fortuitous!

MERIDIAN *of a globe*, or *ſphere*, is the brazen circle, in which the GLOBE hangs and turns.

It is divided into four nineties, or three hundred and ſixty degrees, beginning at the equinoctial: on it, each way, from the equinoctial, on the celeſtial globes, is counted the ſouth and north declination of the ſun or ſtars; and on the terreſtrial globe, the latitude of places north and ſouth. There are two points on this circle, called the *poles*; and a diameter, continued from thence through the centre of either globe, is called the axis of the earth, or heavens, on which they are ſuppoſed to turn round.

On the terreſtrial globes there are uſually thirty-ſix *meridians* drawn, one through every tenth degree of the equator, or through every tenth degree of longitude.

The uſes of this circle are, to ſet the globes to any particular latitude, to ſhew the ſun's or a ſtar's declination, right aſcenſion, greateſt altitude, &c.

MERIDIAN *line*, an arch, or part, of the *meridian* of the place, terminated each way by the horizon.

Or, a *meridian line* is the interſection of the plane of the *meridian* of the place with the plane of the horizon, vulgarly called a *north and ſouth line*, becauſe its direction is from one pole towards the other.

The uſe of a *meridian line* in aſtronomy, geography, dialling, &c. is very great, and on its exactneſs all depends; whence infinite pains have been taken by divers aſtronomers to fix it to the utmoſt preciſion. M. Caſſini has diſtinguiſhed himſelf by a *meridian line* drawn on the pavement of the church of S. Petronio, at Bologna, the largeſt and moſt accurate in the world; being 120 feet in length. In the roof of this church, a thouſand inches above the pavement, is a little hole, through which the ſun's image, when in the *meridian*, falling upon the line, marks his progreſs all the year. When finiſhed, M. Caſſini, by a public writing, informed the mathematicians of Europe, of a new oracle of Apollo, or the ſun, eſtabliſhed in a temple, which might be conſulted, with entire confidence, as to all difficulties in aſtronomy. See GNOMON.

To draw a MERIDIAN *line*. Knowing the ſouth quarter pretty nearly, obſerve the altitude F E (*Tab. Aſtronomy, fig.* 8.) of ſome ſtar on the eaſtern ſide thereof, not far from the *meridian* H Z R N: then, keeping the quadrant firm on its axis, ſo as the plummet may ſtill cut the ſame degree, only directing it to the weſtern ſide of the *meridian*, wait till you find the ſtar has the ſame altitude as before, *f e*. Laſtly, biſect the angle E C *e*, formed by the interſection of the two planes wherein the quadrant is placed at the time of the two obſervations, by the right line H R. This H R is a *meridian line*.

Or thus: on an horizontal plane, from the ſame centre C (*fig.* 9.) deſcribe ſeveral arches of circles B A, *b a*, &c. and on the ſame center C erect a ſtyle, or gnomon, perpendicular to the plane A C B, a foot or half a foot long. About the twenty-firſt of June, between the hours of nine and eleven in the morning, and between one and three in the afternoon, obſerve the points B, *b*, &c. A, *a*, wherein the ſhadow of the ſtyle terminates. Biſect the arches A B, *a b*, &c. in D, *d*, &c. If then the ſame right line D E biſect all the arches A B, *a b*, &c. it will be the *meridian line* ſought.

In regard the extremity of the ſhadow is ſomewhat hard to determine, it is beſt to have the ſtyle flat at top, and to drill a little hole, noting the lucid ſpot projected by it on the arches A B and *a b*, inſtead of the extremity of the ſhadow. Otherwiſe the circles may be made with yellow, inſtead of black, &c.

A good *meridian line* for regulating clocks and watches may be had by the following method: make a round hole, almoſt a quarter of an inch in diameter, in a thin plate of metal; and fix the plate in the top of a ſouth window, in ſuch a manner, that it may recline from the zenith at an angle equal to the co-latitude of your place, as nearly as you can gueſs; for then the plate will face the ſun directly at noon, on the equinoctial days. Let the ſun ſhine freely through the hole into the room, previouſly darkened; and hang a plumb-line to the ceiling of the room, at leaſt five or ſix feet from the window, in ſuch a place as that the ſun's rays, tranſmitted through the hole, may fall upon the line when it is noon by the clock; and having marked the ſaid place on the ceiling, take away the line. Having adjuſted a ſliding-bar to a dove-tail groove, in a piece of wood about eighteen inches long, and fixed a hook into the middle of the bar, nail the wood to the above mentioned place in the ceiling, parallel to the ſide of the room in which the window is; the groove and bar being towards the floor. Then hang the plumb-line upon the hook in the bar, the weight or plummet reaching almoſt to the floor: when this is done, find the true ſolar time, and thereby regulate your clock or watch. Then, at the moment of next noon by the clock, when the ſun ſhines, move the ſliding-bar in the groove until the ſhadow of the plumb-line biſects the image of the ſun on the floor, wall, or on a white ſcreen placed on the north ſide of the line; the plummet or weight at the end of the line hanging freely in a pail of water, placed below it on the floor. By repeated corrections, on the following days, with the ſun and clock, this method may be brought to a very great exactneſs. This *meridian line* will not only be ſufficient for the regulation of clocks and watches, to the true mean time, by equation tables, but alſo for moſt aſtronomical purpoſes. Ferguſon's Lect. on ſelect Subjects, &c. lect. x.

Several authors have invented particular inſtruments and methods for the deſcribing of *meridian lines*, or rather

for determining equal altitudes of the ſun in the eaſtern and weſtern parts of the heavens; as Mr. Grey, Dr. Derham, &c. in the Philoſophical Tranſactions. But as the former of the methods above delivered ſuffices for aſtronomical obſervations, and the latter for more ordinary occaſions, we ſhall forbear to give any deſcriptions thereof.

From what has been ſhewn it is evident, that whenever the ſhadow of the ſtyle covers the *meridian line*, the centre of the ſun is in the *meridian*; and therefore it is then noon. And hence the uſe of a *meridian line* in adjuſting the motion of clocks, &c. to the ſun.

Hence alſo, if the *meridian line* be biſected by a right line O V, drawn perpendicularly through the point C, O V will be the interſection of the *meridian*, and firſt vertical; and, conſequently, O will ſhew the eaſt point, and V the weſt.

Laſtly, if a ſtyle be erected perpendicularly in any other horizontal plane, and a ſignal be given when the ſhadow of the ſtyle covers the *meridian line* drawn in another plane, noting the apex, or extremity, of the ſhadow projected by the ſtyle, a line drawn from that point through that wherein the ſtyle is raiſed, will be a *meridian line*.

One *meridian line* being given, another may be drawn upon another horizontal plane by the following method: hang a thread with a plummet exactly over the ſouth end of the *meridian line* given, and another thread with a plummet over the ſouth end of the plane upon which the *meridian line* is to be drawn; let one perſon obſerve at noon the moment when the ſhadow of the firſt thread falls exactly upon the *meridian* given, and let another obſerver, at the ſame time, mark two diſtant points in the ſhadow of the ſecond thread: a line drawn through thoſe points is the *meridian line* required. By the ſame method may a *meridian line* be found upon a ſouth wall, by marking two points in the ſhadow of a thread hung at a little diſtance from it: if the *meridians* are near, he that obſerves the ſhadow of the firſt thread may let the other know the moment it falls upon the *meridian line* by ſaying *now*: if they are far diſtant, it ſhould be done by the motion of the hand, becauſe ſound takes ſome time to paſs from one place to another. The *meridian line* is the baſis of aſtronomical obſervations: a *meridian line* being found, there may be placed over it a quadrant or ſextant in ſuch a manner, that though it be moved up or down to give it different elevations, in order to view through the ſights of it the celeſtial bodies at their different altitudes; yet the plane of that ſide of the inſtrument upon which the degrees are marked ſhall continue all the while in the plane of the *meridian*. Of this kind is the MURAL *arc* in the royal OBSERVATORY at Greenwich. See MERIDIAN *altitude*.

MERIDIAN *line*, on a dial, is a right line ariſing from the interſection of the *meridian* of the place with the plane of the dial.

This is the line of twelve o'clock, and from hence the diviſion of the hour-line begins.

MERIDIAN, *magnetical*, is a great circle, paſſing through or by the magnetical poles; to which the magnetic needle or needle of the mariners compaſs, if not otherwiſe hindered, conforms itſelf.

MERIDIAN *altitude* of the ſun or ſtars is, their altitude when in the *meridian* of the place where they are obſerved. See ALTITUDE.

To take the MERIDIAN *altitude of the ſtars.* Aſtronomers make two principal kinds of obſervations of the ſtars, the one when they are in the *meridian*, and the other when in vertical circles.

For *meridian* obſervations there are two inſtruments principally uſed, the quadrant and gnomon.

To take the MERIDIAN *altitude with a quadrant.* If the poſition of the *meridian* be known, and the plane of an aſtronomical quadrant be placed in the *meridian* line, by means of the plumb-line ſuſpended at the centre, the *meridian* altitudes of the ſtars, which are the principal obſervations whereon the whole art of aſtronomy is founded, may eaſily be determined.

The *meridian* altitude of a ſtar may likewiſe be had by means of a pendulum-clock, if the exact time of the ſtar's paſſage by the *meridian* be known. Now it muſt be obſerved, that ſtars have the ſame altitude for a minute before and after their paſſage by the *meridian*, if they be not in or near the zenith; but if they be, their altitudes muſt be taken every minute when they are near the *meridian*; and then their greateſt altitudes will be the *meridian* altitudes ſought.

As to the manner of obſerving, it is found very difficult to place the vane of the quadrant in the *meridian* exactly enough to take the *meridian* altitude of a ſtar; for, unleſs there be a convenient place, and a wall, where the quadrant may be firmly faſtened in the plane of the *meridian*, which is not eaſily had, we ſhall not have the true poſition of the *meridian* proper to obſerve the ſtars. It will be much eaſier, therefore, on ſeveral accounts, to uſe the portable quadrant, by which the altitude of the ſtar may be obſerved a little before its paſſage over the *meridian*, every minute, till its greateſt altitude be found. Here, though we have not the true poſition of the *meridian* by this means, yet we have the apparent *meridian* altitude of the ſtar.

Though this method, in the general be very good, and free of any ſenſible error; yet, in caſe a ſtar paſſes by the *meridian* near the zenith, it proves ſomewhat defective; for in theſe kinds of obſervations, the inconvenient ſituation of the obſerver, the variation of the ſtar's azimuth ſeveral degrees in a little time, the alteration of the inſtrument, and the difficulty of replacing it vertically, will prevent the obſervations from being made oftener than in every four minutes; but in each minute the altitude varies about fifteen minutes of a degree, ſo that there will be the difference of a degree in the ſtar's altitude between each obſervation. In ſuch caſes, therefore, it will be better to have the true poſition of the *meridian*, or the exact time wherein the ſtar paſſes the *meridian*, in order either to place the inſtrument in the *meridian*, or to obſerve the altitude of the ſtar the moment it paſſes the *meridian*.

To find the MERIDIAN *altitude of the ſun, &c. by a gnomon*, ſee GNOMON. By other means, ſee ALTITUDE.

MERIDIAN *teleſcope*. See TELESCOPE.

To meaſure the degrees of the MERIDIAN. See DEGREE.

To obſerve the tranſits, or paſſages of the heavenly bodies acroſs the plane of the MERIDIAN. A *meridian* line being found, hang two threads with plummets exactly over it, at a little diſtance from one another, and they will be in the plane of the *meridian*: if you place your eye cloſe to one of the threads, in ſuch a manner that you make it cover the other, and both appear as one thread; when a ſtar is behind the threads, it is in the *meridian*. By the ſame method the ſun may be viewed, through a ſmoaked glaſs; when the threads paſs through his center, he is in the *meridian*: but the beſt way of obſerving the ſun, moon, ſtars, or planets, is through a teleſcope placed in the *meridian*, with two croſs hairs, one of which is in a vertical, the other in a horizontal poſition; when the vertical hair paſſes through the center of the ſun he is in the *meridian*.

MERIDIANI, in *Antiquity*, is a name which the Romans gave to a kind of gladiators, who entered the arena about noon, after the beſtiarii (who fought in the morning againſt beaſts) had finiſhed. See GLADIATOR.

They were thus called from *meridies*, i. e. *noon*, the time when they exhibited their ſhews.

The *meridiani* were a ſort of arileſs combatants, who fought man with man, ſword in hand: hence Seneca takes occaſion to obſerve, that the combats of the morning were full of humanity, compared with thoſe which followed.

MERIDIONAL *diſtance*, in *Navigation*, the ſame with departure, or eaſting and weſting, being the difference of longitude between the meridian, under which the ſhip now is, and any other meridian, which ſhe was under before.

MERIDIONAL *parts*, *miles*, or *minutes*, in *Navigation*, are the parts by which the meridians in a *Mercator's* CHART do increaſe, as the parallels of latitude decreaſe.

The co-ſine of the latitude of any place being equal to the radius, or ſemidiameter, of that parallel; therefore, in the true ſea-chart, or nautical planiſphere, this radius being the radius of the equinoctial, or whole line, of ninety degrees, the *meridional* parts at each degree of latitude muſt increaſe, as the ſecants of the arch contained between that latitude, and the equinoctial, do decreaſe.

In order to underſtand this, it is neceſſary to conſider, 1. that the diſtance between any two meridians at the equator is to their diſtance in any parallel of latitude as *radius* is to the co-ſine of that latitude. Let P D F E, *Tab. Navigation, fig.* 13. repreſent the fourth part of a ſphere; E being the center, P the pole, E D the radius of the equator, A B the radius of a parallel of latitude: then each of the arcs P B D, P C *d*, will repreſent a quadrant of a meridian; D *d* an arc of the equator; and B C an arc of a parallel of latitude: D B expreſſes the latitude, and P B the complement of the latitude, whoſe right line is B A. But the circumference of a circle, whoſe radius is E D, is to the circumference of a circle, whoſe radius is A B, and conſequently like arcs D *d*, B C, intercepted between the ſame two meridians, as E D is to A B, i. e. as radius to the co-ſine of the latitude. Whence it is eaſy to conſtruct a table ſhewing

in

in what proportion the degrees of longitude diminish in every latitude. See such a table under article DEGREE *of latitude*.

2. Any part of a parallel of latitude is to a like part of a meridian, as radius to the secant of the latitude to that parallel. Let P D E, *Tab. Navigation, fig.* 14. represent a quadrant of a meridian, where P is the pole, and D E the arch of the equator; A B is the radius of a parallel of latitude, or the co-sine of the latitude, whose sine is B F, and secant E C. Then E F : E B :: E D : E C; or co-sin. latitude : rad. :: rad. : secant of the latitude, in that parallel. Therefore, part of a parallel of latitude is to a like part of the equator as the radius is to the secant of the latitude to that parallel: consequently, since like parts of the meridian and equator are equal, as great circles, any part of a parallel of latitude is to a like part of a meridian, as radius to the secant of the latitude to that parallel.

3. The distance of any parallel of latitude, A, from the equator is expressed by the sum of the secants of all the arcs between the equator and that parallel. For, as radius to the secant of the latitude A, so is a diminithed degree of longitude in the latitude A, or a degree of that parallel to a degree of the meridian: but the degrees of latitude, or of the meridian, are to be lengthened in proportion as the degrees of longitude decrease: therefore, as radius to the secant of the latitude A, so is a natural degree of the meridian to a lengthened degree in the latitude A; radius being here as unity, and one natural degree as unity also: therefore, the length of a degree in any latitude is as the secant of that latitude, or may be expressed by that secant: but the distance of any parallel from the equator is the sum of all the successive arcs between the equator and that parallel: consequently, the distance of that parallel is expressed by the sum of the secants of all these arcs between the equator and that parallel of latitude: and, therefore, by the addition of the secants of small arcs, the distances of the parallels of latitude from the equator are obtained.

The tables, therefore, of *meridional* parts, in books of navigation, are to be made by a continual addition of secants, calculated in some books, as in sir Jonas Moor's Tables, Robertson's Navigation, &c. for every degree and minute of latitude; and these will serve either to make or graduate a Mercator's chart, or to work the Mercator's sailing.

Mr. Wright, to whom we are indebted for this excellent discovery, made his table for the division of the nautical meridian, or the table of *meridional* parts, as follows: the *meridional* parts for 1 minute he made equal to the secant of 1 minute; those of 2′ equal to the sum of the secants of 1′ and 2′; those of 3′ equal to the sum of the secants of 1′, 2′, and 3′; those of 4′ equal to the sum of the *meridional* parts of 3′ and the secant of 4′; and so on by a constant addition of the secants: Mr. Oughtred, sir Jonas Moor, Dr. Wallis, Dr. Halley, and others, have endeavoured to find methods of constructing these tables with greater accuracy than by the addition of the secants to every minute.

To use them you must enter the table with a degree of latitude at the head, and with the minute on the first column towards the left hand; and in the angle meeting you will have the *meridional* parts.

Having the latitude of two places, to find the *meridional* miles, or minutes, between them; consider whether the places be, one under the equinoctial, and the other wide thereof, or the one on the one side of the equinoctial, and the other on the other; or whether they both lie on the same side.

If one place lie under the equator, the *meridional* minute next under the degree of latitude of the other place, is the *meridional* difference of latitude, or latitude inlarged.

If one be in north, and the other in south latitude, the *meridional* minutes, corresponding to the two latitudes, added together, give the *meridional* minutes between them.

Both places lying towards the same pole, subtract the *meridional* parts answering to the less latitude, from those of the greater, the remainder gives the *meridional* minutes.

In the Philosophical Transactions, N° 219. Dr. Halley has given a very curious paper relating to the division of the nautical meridian, by a quite different method from Mr. Wright's, and containing a method of performing the problems of sailing according to the true chart, by the help of Brigge's, or the common table of logarithmic tangents, without a table of *meridional* parts. Dr. Halley avails himself of a principle, first accidentally discovered by Mr. Henry Bond, and published about the year 1645, that the meridian line was analogous to a scale of logarithmic tangents of half the complements of the latitude. This analogy was first demonstrated by Mr. James Gregory, in his Exercitationes Geometricæ, published in 1668, and more elegantly and concisely by Dr. Halley himself; who has also shewn *(ubi supra)* how to apply this analogy, by means of any system of logarithms, for computing the interval of the *meridional* parts answering to any two given latitudes. The reader may find this subject well illustrated by Dr. Robertson, in his Elements of Navigation, book viii. p. 142, &c. See also Phil. Trans. vol. xlvi. p. 550, &c.

To find the *meridional* parts to any spheroid, with the same exactness as in a sphere.

Let the semi-diameter of the equator be to the distance of the focus of the generating ellipse, from the center as m to 1. Let A represent the latitude for which the *meridional* parts are required, s the sine of the latitude, the radius being unity; find the arc B, whose sine is $\frac{s}{m}$; take the logarithmic tangent of half the complement of B, from the common tables; subtract this logarithmic tangent from 10.0000000, or the logarithmic tangent of 45°; multiply the remainder by $7915.7044078 \frac{s}{m}$, &c. and the product subtracted from the *meridional* parts in the sphere, computed in the usual manner for the latitude A, will give the *meridional* parts expressed in minutes for the same latitude in the spheroid, provided it be oblate.

Example: if $m : 1 :: 100 : 99$, then the greatest difference of the *meridional* parts in the sphere and spheroid is 76.6929 minutes: in other cases it is found by multiplying the remainder above mentioned by 1174.078.

When the spheroid is oblong, the difference of the *meridional* parts in the sphere and spheroid, for the same latitude, is then determined by a circular arc. Phil. Trans. N° 462. sect. 14. See also Maclaurin's Fluxions, art. 895—899.

Mr. Murdoch has solved this problem by infinite series, and has computed a table of *meridional* parts for an oblate spheroid, such as is mentioned in the foregoing example. See his Treatise, intituled, Mercator's Sailing applied to the true Figure of the Earth. Lond. 1741. 4to.

MERIS, *μερις*, *a part*, in *Music*, an appellation given by Mr. Sauveur to the forty-third part of an octave. See Mem. Acad. Scienc. 1701.

MERIT, in *Theology*, is used to signify the moral goodness of the actions of men, and the reward due to them.

The Romish schoolmen distinguish two kinds of *merit* towards God: the one of *congruity*, the other of *condignity*.

MERIT *of congruity* is when there is no just proportion between the action and the reward; but he who bestows the reward supplies, by his goodness or liberality, what was wanting in the action. Such is the *merit* of a son towards his father: but this is only *merit* in an improper sense.

MERIT *of condignity* is when there is an absolute equality and a just estimation between the action and the reward: as in the wages of a workman.

Those of the reformed religion disclaim all *merit of condignity* towards God; even their best works, they own, do not *merit* at his hands. Hence the doctrine of *condign-merit* makes one of the great articles of controversy between the Romish and reformed churches.

MERIT, *order of*. See ORDER.

MERLANGUS, in *Ichthyography*, a name given by Bellonius, and some other authors, to a small species of whiting, or *asellus mollis*, called by the Venetians *molla*, and by some other nations the *capelan*.

MERLANUS, a name given by some writers in ichthyography to the common WHITING, or *asellus mollis sive albus*.

MERLIN, in *Ornithology*, the name of the yellow-legged FALCON.

The *merlin* does not breed in England, but migrates here in October, about the time when the booby disappears. It flies low, and is often seen along the sides of roads, skimming from one side of the hedges to the other, in search of prey. See ÆSALON, and HAWK, and *Tab.* III. *Birds.* N° 32.

MERLON, in *Fortification*, that part of the parapet, from fifteen to eighteen feet in length, which lies between two EMBRASURES.

The word comes from *merula*, or *merla*, which, in the corrupt Latin, was used for *a battlement*.

To take out the *merlons*, measure from each end of the wall twelve feet, there stick a stake, and plant other stakes at every intermediate eighteen feet: when this is done on the inside of the wall, let other stakes be planted on the outside, either directly opposite to the former, or in the line towards the place where the gun

is more particularly intended to deſſect its ſhot. Plant other ſtakes on the inſide, one a foot diſtant on each ſide of the former, and this will leave ſpaces of two feet each for the inner opening of embraſures; then, on the outſide, plant other ſtakes at five or ſix feet diſtance from the former ones, one on each ſide, and the ſpaces of ten or twelve feet will be marked out for the outſide openings of the embraſures. In the direction of the pickets, which limit the inner and outer openings of the embraſures, let ſingle rows of faſcines be ſtaked down across the wall, and theſe will be the ſides of the embraſures: fill the intermediate ſpaces, or *merlons*, with rows of faſcines laid lengthwiſe to the wall, and this will be the firſt floor of the *merlon*, which is to be picketted down, and the hollows filled with earth. Let other floors be raiſed in like manner, until the *merlons* are carried up to about five or ſix feet, or more if neceſſary; and on the top of each let a bed or floor of earth be laid of about eight or twelve inches thick.

MERLUCIUS, *gadus merluccius* of Linnæus, in *Ichthyology*, the name of a fiſh commonly called the HAKE, and by ſome authors the *aſellus alter*.

It is a moderately large fiſh, growing to two feet or more in length, and reſembling the common pike in figure, from whence it has its name, *merluccius, quaſi maris lucius, the ſea pike*. It in ſome meaſure reſembles the common whiting in colour, the back being of a pale greyiſh hue, and the belly of a dirty white; the head is flat and broad; the mouth very wide; and the teeth very long and ſharp, particularly thoſe of the lower jaw. It is covered with ſmall ſcales. Its tail is not forked. It is caught in the Engliſh and other ſeas, and being a coarſe fiſh is ſeldom admitted to table, either freſh or ſalted: when cured it is known by the name of *Poor John*. *Tab.* III. *Piſc.* N° 26.

There was formerly a large ſtationary fiſhery of hake on the Nymph bank off the coaſt of Waterford: two ſhoals of theſe fiſh appeared there twice in the year; and they were ſalted and ſent to Spain, particularly to Bilboa.

MERMAID, or MERMAN, a ſea-creature, frequently talked of, and ſuppoſed half human and half a fiſh.

However naturaliſts may doubt of the reality of *mermen* or *mermaids*, if we might believe particular writers, there ſeems teſtimony enough to eſtabliſh it. In the year 1187, as Lavrey informs us, ſuch a monſter was fiſhed up in the county of Suffolk, and kept by the governor for ſix months. It bore ſo near a conformity with man, that nothing ſeemed wanting to it beſides ſpeech. One day it took the opportunity of making its eſcape, and plunging into the ſea, and was never more heard of. Hiſt. d'Angleterre, p. i. p. 403.

In the year 1430, we are told, that, after an huge tempeſt, which broke down the dykes in Holland, and made way for the ſea into the meadows, &c. ſome girls of the town of Edam, in Weſt-Friezland, going in a boat to milk their cows, perceived a *mermaid* embarraſſed in the mud with a very little water. They took it into their boat, and brought it with them to Edam, dreſſed it in women's apparel, and taught it to ſpin. It fed like one of them, but could never be brought to offer at ſpeech. Some time after it was brought to Haerlem, where it lived for ſome years, though ſtill ſhewing an inclination to the water. Parival relates that they had given it ſome notionsof a Deity, and that it made its reverences very devoutly whenever it paſſed by a crucifix. Delices d'Hollande.

In the year 1560, near the iſland of Manar, on the weſtern coaſt of the iſland of Ceylon, ſome fiſhermen are ſaid to have brought up, at one draught of a net, ſeven *mermen* and *mantæ*; of which ſeveral Jeſuits, and among the reſt F. Hen. Henriques, and Dimas Boſquez, phyſician to the viceroy of Goa, are ſaid to have been witneſſes. And it is added, that the phyſician, who examined them with a great deal of care, and made diſſections thereof, aſſerted that all the parts, both internal and external, were found perfectly conformable to thoſe of men. See the Hiſt. de la Compagnie de Jeſus, p. ii. tom. iv. N° 276, where the relation is given at length.

We have another account, as well atteſted, of a *merman*, near the great rock called Diamond, on the coaſt of Martinico. The perſons who ſaw it gave in a preciſe deſcription of it before a notary; they affirmed, that they ſaw it wipe its hand over its face, and even heard it blow its noſe.

Another creature of the ſame ſpecies, was caught in the Baltic, in the year 1531, and ſent as a preſent to Sigiſmund king of Poland, with whom it lived three days, and was ſeen by all the court. And another very young one was taken near Rocca de Sintra, as related by Damian Goes.

The king of Portugal, and the grand maſter of the order of St. James, are ſaid to have had a ſuit at law, to determine which party theſe monſters belonged to. See SEA-*cow*, and SIREN. See Pontoppiddan's Nat. Hiſt. of Norway, vol. ii. p. 186, &c.

MERO *natu*. See EX *mero*.

MEROPS, in *Ornithology*, the name of a bird called alſo *apiaſter*, and in Engliſh the *bee-eater*.

It reſembles the king fiſher in ſhape, and is of the ſize of a black-bird. Its beak is long, black, and a little crooked, and the irides of its eyes are a fine red; its head is long and large; the feathers growing at the inſertion of the upper chap are of a bluiſh green, but thoſe in the middle of the head are white; the crown, however, a little more backward, is of a reddiſh brown, ſometimes with a ſlight admixture of green; and there runs on each ſide a black line from the angle of the beak through the orbit of the eyes; its neck and ſhoulders are green, but with a caſt of redneſs; and its belly and breaſt are blue; the tips of the long wing-feathers are blackiſh, and the reſt are variegated with a bright green and a fine orange-colour; its tail is of a fine blue, and the two middle feathers of it are longer than any of the others. Its legs are very ſhort and thick, and are of the ſame form with the king-fiſher's. It is very common in Italy, and extremely ſo in the iſland of Crete; but it is not known in England. It feeds on bees and other inſects, and ſometimes on ſeeds. Ray. See *Tab.* III. *of Birds*, N° 33.

The entire bird, and its heart, are recommended in cardiac, ictherical, and ſtomachic diſorders: the gall mixed with honey and the juice of rue is ſaid to cure ſuffuſions of the eyes.

In the Linnæan ſyſtem, *merops* forms a genus of *pica*, characteriſed by a bent, compreſſed, carinated beak; a tongue fringed at the apex; and feet formed for walking; and comprehending ſix other ſpecies, beſides the bee-eater above deſcribed. *Tab.* III. *Piſc.* N° 24.

MEROS, in *Ichthyology*, the name of a very large American fiſh, growing to five or ſix feet long, and called by the Braſilians, *cuyapu-guacu*. Its head is very large, and its mouth wide and toothleſs; its eyes have a black pupil and a yellow iris; it hath five fins, one running the whole length of the back and reaching nearly to the tail, the anterior part of this is narrow, and armed with ſmall but ſharp ſpines; the other part is broader, and ſuſtained by ſofter rays; behind the anus is one like the hinder part of that on the back, and two others behind the gills, which are large and broad; the tail-fin is very large and broad, and much more ſo at its extremity than at its origin; the ſcales are ſmall; the *head*, back, and ſides are of a browniſh grey; and its belly white. It is accounted a well-taſted fiſh. Ray. *Tab.* III. *Piſc.* N° 24.

MEROVINGIAN *character* derives its name from Merouée, the firſt king of France of that race, which reigned 333 years, from Pharamond to Charles Martel. This race is ſaid by ſome to have terminated in Childeric III. A. D. 751. There are many MSS in the French libraries ſtill extant in this character. See Spect. de la Nat. vol. vii. p. 192.

MERSION. See IMMERSION, and EMERSION.

MERUIT. *Quantum* MERUIT. See QUANTUM.

MERULA, in *Ornithology*. See BLACK-*bird*, and AMZELL; and *Tab.* III. *Birds*, N° 29 and N° 30.

MERULA, in *Ichthyology*, the name of a ſea fiſh of the turdus or waſſe kind, of a ſhort and flat figure, and all over of a dull and dead bluiſh black. The back, ſides, and belly are all of this colour, as are alſo even the fins and tail. It is a fiſh not much eſteemed, being of an inſipid watery taſte, but is ſold among the poorer ſort in the Italian markets. Rondelet.

MERULA *aquatica*, the name of a bird, called the *water*-OUZEL in Engliſh.

MERULA *fluviatilis*, in *Ichthyology*, a name given by Schoneveldt, and ſome other writers, to the common tench. Theſe are whimſical and arbitrary names, and expreſs nothing. Artedi has much better diſtinguiſhed the fiſh, having taken away even its generical name, and reduced it to the *cyprini*, of which genus it is evidently a ſpecies: he has called it the *black mucous cyprinus*, with an even not forked or invected tail. This is a name by which it can never be miſtaken.

MERULA *ſanatilis*, a name given by ſome to the TORDO *marina*.

MERZENIUS, in *Botany*, a name uſed by ſome authors for MARJORAM.

MES-AIR, or MEZAIR, in the *Manege*, is a manege half TERRE *à terre*, and half COURVET: ſo that the *mezair* is higher than the action of the former, and lower than that of the latter. In this action uſe the ſame AIDS as in working upon *curvets*. Give the aids of the leg with delicacy, and no ſtronger than is juſt neceſſary to carry your horſe forward. Remember when you cloſe your legs to make him go forward, to puſh with the outward in ſuch a degree as to keep your horſe confined, and to aſſiſt

assist the other in driving him forward; as it is not necessary to lay so much stress on the inner leg, because that serves only to guide the horse, and make him cover and embrace the ground that lies before him. Berenger's Horsemanship, vol. ii. p. 116.

MESANGIA, in *Natural History*, the name of a bird common in France and Italy; it is of the size and shape of the ficedula, and differs from it very little, except the having a black spot upon the head. This seems to be the *melanocephas* of the ancients, who supposed, as many do at this time, that the ficedula changed into this bird. The ficedula, or fig-eater, comes into the gardens in France only at the time when the figs, which are its proper food, are ripe: these it devours in an insatiable manner, and, as soon as it has done with them, goes away again. Soon after this the *motacilla* or black-cap appears, and is supposed to be the same bird, with the addition of this beautiful ornament. The ancients were very fond of this imaginary change of one bird into another; and Aristotle tells us, that the upupa is the same bird with the cuckow, only changed in the colour and disposition of its feathers. Æschylus tells us in the same manner, according to the opinion of his times, that the cuckow sings all the summer, and after that disappears; and that soon afterwards it comes again in a new form, with a plume upon its head, and is called the *upupa*.

MESARÆUM, *παραορτιον*, in *Anatomy*, the same with MESENTERY.

MESARÆUM is also used in a more restrained sense, for a part or division of the MESENTERY, being that fastened to the small guts.

That part of the mesentery which is fastened to the thick guts is called MESOCOLON.

MESARAIC *vessels*, in the general sense, are the same with MESENTERIC.

In common use *mesaraic* is more frequently applied to the veins and mesenteric to the arteries of the mesentery.

MESAZONTES, *μεσαζοντες*, officers under the emperors of Constantinople. See MEDIATOR.

MESE, in the *Greek Music*, was the ultimate note of the meson tetrachord, and answers to Guido's *a la mi re*. See DIAGRAM.

MESEMBRYANTHEMUM, in *Botany*, the name by which Dillenius, Linnæus, and others, have called the plants usually named *ficoides*, or *fig-marygold*, a genus of the *icosandria pentagynia* class. Its characters are these: the flower hath a permanent spreading empalement of one leaf, which is cut at the top into five acute parts; it hath one petal, which is cut into many linear segments almost to the bottom, and ranged in several series, but joined together at their base; within these are ranged a great number of hairy stamina; under the flower is situated an obtuse five-cornered germen, supporting sometimes five, and often ten or more styles; the germen afterwards becomes a roundish fleshy fruit, having as many cells as there are styles, filled with small seeds.—Linnæus enumerates forty-five, and Miller forty-seven species.

These plants are most of them natives of the Cape of Good Hope, from whence these seeds were first brought to Holland, and the plants raised in many curious gardens, and have since been communicated to most parts of Europe. Most plants of this genus have beautiful flowers, which appear at different seasons of the year.

All the sorts are perennial plants, except two, which are annual. The perennial sorts are easily propagated by cuttings during any of the summer months; such of them as have thrubby stalks and branches do very readily take root, when planted in a bed of light soil, and covered either with mats or glasses; but when they are covered with the latter, they must be shaded every day when the sun is warm.

When the cuttings are planted, it will be necessary to give them a little water to settle the ground about them, but it should be done with caution, for it is to be observed in general, that too much wet will spoil them.

Those whole stalks and leaves are very succulent, should have their cuttings taken from the plants ten days or a fortnight before they are planted, that their wounded part may heal and dry. They should be guarded from wet by glasses, and require less watering than the others.

The first sort called the Egyptian kali, grows naturally in Egypt, and is burnt for pot-ash: and is esteemed the best sort for making hard sope and the best glass. The second sort is the Ice-*plant*. Miller.

MESENTERIC, or MESARAIC, an epithet given to two arteries arising from the descending aorta, and proceeding to the mesentery.

There is an upper, or superior *mesenteric*, which goes to the upper part of the mesentery; and a lower, or inferior *mesenteric*, which distributes itself through the lower part. See *Tab. Anat. (Angeiol.) fig.* 1. *n.* 43. 45.

We have also a *mesenteric vein*, composed of an infinity of veins, proceeding from the mesentery; which, with the vena splenica, arising from the spleen, forms the vena porta.

Ruysch painted the *mesaraic* arteries and veins as having different courses in the distribution of their branches in the intestines. Albinus attributes this mistake to Ruysch's having injected the arteries at one part of the intestines, and the veins at another; and by a single figure representing the internal cellular membrane of the ilium, with both arteries and veins injected, shows their courses to be the same.

Anatomists also reckon a *mesenteric nerve*, which arises from the intercostal, and sends several branches to the mesentery.

MESENTERIC *plexus*, a plexus, or piece of net-work, formed by the branches or ramifications of the par vagum.

The *plexus mesentericus magnus*, or *great mesenteric plexus*, is formed out of the concurrent branches of several other plexuses, and sends its nervous fibres through the whole mesentery, along with the mesaraic vessels, which, with various circumligations, they accompany to the intestines.

MESENTERIC, *emplast.* See OMPHALO *mesenteric*.

MESENTERICA *febris*. See *Intestinal* FEVER.

MESENTERY, MESENTERIUM, formed of *μεσος*, *middle*, and *εντερον*, *intestine*, or MESARÆUM, in *Anatomy*, a fatty membranous body; thus called as being placed in the middle of the intestines, which it connects to one another.

The *mesentery* is almost of a circular figure, with a narrow production; to which the end of the colon, and the beginning of the rectum, are tied.

It is about four fingers and a half in diameter; its circumference, being full of plaits and foldings, is about three ells in length. The intestines are tied like a border on this circumference of the *mesentery*: there are three inches of the intestines thus fastened.

The *mesentery* itself is strongly tied to the three first vertebræ of the loins. It is composed of three lamina; the inner, upon which the glands and fat lie, and the veins and arteries run, is its own proper membrane; and the other two, which cover each side of the proper membrane, come from the peritonæum. Between the two external lamina of the *mesentery* run the branches of the arteria mesenterica, superior and inferior, which bring the blood to the intestines; and the vena mesaica, which, being branches of the porta, carry the blood back to the liver. Here the large branches of both arteries and veins, communicating with one another, march directly to the guts; where, with the nerves that form the plexus mesentericus, they divide into an infinite number of small branches, which spread themselves extremely fine upon the coats of the intestines. The vena lactea, and lymphatic vessels, run likewise upon the *mesentery*, in which there are also several vesicular glands; the biggest of which, in the middle of the *mesentery*, is called *pancreas Asellii*; these glands receive the lympha and chyle from the lacteal veins.

The *mesentery* has been ordinarily divided into two parts, the mesaræum, and mesocolon: the first appended to the intestina tenuia, and the latter to the crassa: but this is a division of no great moment.

The use of the *mesentery* is, first, to gather the intestines into a narrow compass, that the courses of the chyliferous vessels toward their common receptacle may be but short; next, to cover and protect them and the blood-vessels, and to correct and dispose the intestines, so as to secure them from any entanglement that might hinder their peristaltic motion.

The *mesentery* is subject to inflammation, which is attended with a languid slow fever, without any thirst or other violent symptom, a loss of appetite, a sense of tension and weight below the stomach, with much hardness, and only discoverable by pressing upon it. Inflammations of the *mesentery* generally terminate in abscesses, and bring on a corruption of the membrane; the morbific matter is sometimes translated to other parts, without being removed from the habit; so that the disorder often recurs. The method of cure is the same as that for an inflamed LIVER or SPLEEN.

MESERA, a name given by some medical writers to the Alexandrian tutty.

MESHES *of nets*, the openings or interstices between the threads.

MESIRE, a name given by Avicenna to a distemperature of the liver, attended with a sense of heaviness, rumor, inflammation, and pungent pain, and always with thirst, a dry mouth, and a parched black tongue.

MESTICUM, among the Romans, a toll paid for a place to sell goods in the forum.

MESMARCHURES, in the *Manege*. See PASTERN.

MESN, or MESNE, a term in *Law*, fignifying him who is lord of a manor, and fo hath tenants holding of him; yet he himfelf holds of a fuperior lord.

The word is properly derived from *maifne, quaſi minor natu*; becaufe his tenure is derived from another, from whom he holds.

MESNE alſo denotes a writ, which lieth where there is lord *meſne* and tenant; and the tenant is diſtrained for ſervices due from the *meſne* to the fuperior lord.

This is in the nature of a writ of right; and in this caſe the tenant ſhall have judgment to be acquitted or indemnified by the *meſne* lord; and if he makes default therein, or does not appear originally to the tenant's writ, he ſhall be forejudged of his *meſnalty*, and the tenant ſhall hold immediately of the lord paramount himſelf.

MESNE *proceſs*. See PROCESS.

MESOCHOROS, μεσοχορος, among the ancients. The *meſochori* were muſicians who preſided in concerts, and by beating a deſk in a regular manner with their feet, directed the meaſure of the muſic. For this purpoſe in the theatre they wore wooden clogs on their feet, that they might be better heard, which were called by the Greeks, *cruperia*.

MESOCHORUS, among the Romans, was alſo uſed for a perſon in public aſſemblies, appointed to give the ſignal for ACCLAMATION at the proper time, that all might join in it at once.

MESOCOLON, μεσοκολον, in *Anatomy*, that part of the MESENTERY, which, having reached the extremity of the ileum, contracts and changes its name. At this place the particular lamina, which is turned to the right ſide, forms a ſmall tranſverſe fold, called ligamentum coli dextrum. Afterwards the *meſocolon* aſcends towards the right kidney, where it ſeems to be loſt by the immediate adheſion of the colon to that kidney, and to the firſt incurvation of the duodenum. Then it appears again, and increaſing in breadth, continues its courſe almoſt tranſverſely under the liver, ſtomach, and ſpleen, where it begins to turn downward, under the left hypochondrium, towards the kidney on the ſame ſide. Through the whole courſe the *meſocolon* extends in breadth, and forms nearly a tranſverſe ſemicircular plane, very little plaited at its great circumference. By this circumference or edge, it is connected to the colon, and hides that ligamentary band of this inteſtine, which runs along its ſmall curvature. By its ſhort or ſmall edge, it forms the triangular caſe of the duodenum, and by its great edge, the external coat of the colon, in the ſame manner as the meſentery does that of the ſmall inteſtines. As it paſſes under the large extremity of the ſtomach, it adheres a little to the lower portion of that extremity, as the diaphragm does to the upper. Having got below the left kidney, it contracts and forms another tranſverſe fold, called ligamentum coli ſiniſtrum. Afterwards it expands again, and runs down on the left pſoas muſcle, towards the laſt vertebra of the loins. This deſcending portion is fixed to the convolutions of the colon in the ſame manner as the ſuperior portion is to the arch of that inteſtine. The *meſocolon* by its adheſion to the colon forms a kind of ſeptum tranſverſum, between the ſmall inteſtines and the viſcera contained in the epigaſtrium; and this ſeptum ſupports the liver and ſtomach under the arch of the diaphragm, juſt as much as it is ſuſtained by the inteſtines. Winſlow.

MESOCURUS, μεσοκουρος, in *Antiquity*, an actreſs in tragedies, who had the middle part of her head ſhaven: but others think that *meſocuros* ſignifies a girl or very young woman.

MESOGLOSSI, a name given by ſome writers to the muſcles of the tongue, more uſually called by anatomiſts, the GENIOGLOSSI.

MESOLABE, MESOLABIUM, a mathematical inſtrument, invented by the ancients for finding two mean proportionals mechanically, which they could not come at geometrically. See PROPORTIONAL.

It conſiſts of three parallelograms, moving in a groove to certain interſections. Its figure is deſcribed by Eutocius, in his commentary on Archimedes.

MESO-LOGARITHM, a term uſed by Kepler to ſignify the logarithms of the co-ſines and co-tangents; the former of which lord Neper calls *antilogarithms*, and the latter *differentiales*.

Theſe are alſo called *artificial ſigns and tangents*.

MESO-PLEURII, derived from μεσος, *middle*, and πλευρα, *rib*, in *Anatomy*, the intercoſtal muſcles.

MESO-PLEURII is ſometimes alſo uſed for the intermediate ſpaces between the coſtæ, or RIBS.

MESOPYCNI, μεσοπυκνοι, in the *Ancient Muſic*, was an appellation given to ſuch chords as formed the middle notes of the ſyſtà. There were five *meſopycni* in the ſcale. See PYCNI and SPISSUM.

MESO-RECTUM, in *Anatomy*, is a particular production of the peritonæum, inveſting the inteſtinum rectum.

This production is very narrow, and about the middle of the foreſide of the rectum; it forms a tranſverſe ſemicircular fold, which appears when the inteſtine is empty, but is loſt when it is filled. Winſlow.

MESORO, in *Ichthyology*, a name given by Salvian to that fiſh which we call the butterfly-fiſh, the blennus or BLENNIUS of other authors.

MESORO is alſo uſed by the Italians for the fiſh commonly called the URANOSCOPE, or *ſtar-gazer*.

MESOTHENAR, in *Anatomy*, a flat and nearly triangular muſcle, lying between the firſt phalanx of the thumb and the bottom of the palm of the hand. It is inſerted by a very broad baſis in the ligament which connects the os magnum to that which ſupports the thumb. It is likewiſe inſerted along the internal or angular part of that bone of the metacarpus which ſupports the middle finger, and in the ſmall extremity of that which anſwers to the index; from thence the fibres contracting to an angle, terminate in a flat tendon of different breadths, which is inſerted in that ſide of the head of the firſt phalanx of the thumb, which is turned to the hollow of the hand, and in the neighbouring part of the baſis of the ſecond phalanx, by means of the ſecond ſeſamoide bone belonging to that joint. Winſlow.

MESPILEUS *lapis*, in *Natural Hiſtory*, a name given to ſome ſpecies of the echinitæ, from their reſemblance to the ripe fruit of a medlar. This was a name given them before they were much known, and they were ſome time afterwards called, from their five lines on the ſurface, *pentaenchi*.

MESPILUS, in *Botany*. See MEDLAR.

MESS, in *Sea-Language*, denotes a particular company of the officers or crew of a ſhip, who eat, drink, and aſſociate together, whence *meſs-mate*, denoting one of theſe, with reſpect to another.

MESSALIANS. See EUCHITES.

MESSE, or MASS, *miſſa*. See MASS.

MESSA *baſſa*, ſilent maſs whiſpered by the prieſt during a muſical performance.

MESSE *de capella*, in the *Italian Muſic*, is uſed for maſſes ſung by the grand chorus. In theſe various fugues, double counterpoints, and other ornaments are uſed.

MESSE *concertate*, in the *Italian Muſic*, maſſes wherein the parts reciting are interwoven with choruſes.

MESSENGERS, in the *Engliſh Polity*, are carriers of letters and meſſages; or, more particularly, certain officers, chiefly employed under the direction of the ſecretaries of ſtate, and always in readineſs to be ſent with all manner of diſpatches, foreign and domeſtic.

They are always employed with the ſecretaries warrants, to take up perſons for high treaſon, or other offences againſt the ſtate, which do not ſo properly fall under the cognizance of the common law; and, perhaps, are not proper to be divulged in the ordinary courſe of juſtice. The priſoners they apprehend are uſually kept at their own houſes, for each of which they are allowed by the government 6*s*. 8*d*. per day. When they are diſpatched abroad, they have an allowance for their journey, as ſtated; viz. to Paris, 30*l*. to Holland, 25*l*. to Edinburgh, 30*l*. to Ireland, 30*l*. and ſo to other places in proportion. Part of which money is advanced to them for their journey.

Of theſe *meſſengers* in ordinary there are forty, at 45*l*. a year, beſides daily pay when employed. Their poſts, if purchaſed, are eſteemed worth 300*l*.

MESSENGERS *of the exchequer*, are officers attending the exchequer, in the nature of purſuivants: they are four in number: their buſineſs is to attend the chancellor and auditor, and to carry their letters, preceipts, &c.

MESSENGER *of the preſs*, a perſon, who, by order of the court, ſearches printing-houſes, bookſellers ſhops, &c. in order to diſcover ſeditious books, &c.

There are alſo other officers diſtinguiſhed by this appellation; as the *meſſenger* of the lord chancellor, of the great wardrobe, the two *meſſengers* of the yeomen of the guards, *meſſenger* to the gentlemen penſioners, nine *meſſengers* to the commiſſioners of bankruptcy, &c.

MESSERSMIDIA, in *Botany*, a genus of the *pentandria monogynia* claſs: the corolla of which is infundibuliform, and the fruit a ſubroſe berry, ſeparating into two parts, each of which contains a double ſeed. There is only one ſpecies.

MESSIAH, a term ſignifying *anointed*, or *ſacred*; and, in that ſenſe, applied to kings and prieſts; but, particularly, by way of eminence, to JESUS CHRIST, the Saviour promiſed by the prophets of the old Jewiſh law.

The word comes from the Hebrew מָשִׁיחַ, *maſſiach*, *anointed*, of the verb מָשַׁח, *maſſach*, *to anoint*; whence Jeſus Chriſt claims the title on a manifold account: 1.

As having been anointed king of kings from all ages. 2. As chief of the prophets. 3. As high priest of the law of grace, or priest for ever after the order of Melchizedek.

The prophecies in the Old Testament, which relate to the coming of the *Messiah*, are very numerous: some of which may be found in Gen. iii. 15. xlix. 10. Isaiah, vii. 14. c. xi. c. lii. liii. which the Targum of Jonathan interprets of the *Messiah*, Dan. ix. 25. Micah, iv. 1—5. c. v. 2—4. Haggai, ii. 6, 9. Zech. iii. 8—10. vi. 12, 13. ix. 9—12. Mal. iii. 1—4. iv. 2—6. &c.

It has been also urged, that there are some remarkable passages in Josephus, Philo, Tacitus, Suetonius, and Celsus, which shew that the expectation of the *Messiah*, agreeable to the scripture prophecies, prevailed in some degree among the heathen nations; and many have supposed that there is some reference of this kind in the fourth eclogue of Virgil. We shall only add farther, that the best Christian writers lay little stress on the prophecy of Christ cited by Abulpharagius, out of the books of Zerdusht or Zoroaster, nor on the pretended prophecy of Confucius, among the Chinese; nor on those of the SIBYLLINE oracles, among the Romans.

The Jews still wait for the coming of the *Messiah*, being infatuated with the notion of a temporal *Messiah*, that is to be a mighty conqueror, and to subdue all the world. Most of the modern rabbins, according to Buxtorf, believe that the *Messiah* is already come, but that he keeps himself concealed, and will not manifest himself because of the sins of the Jews. Some of the Jews, however, in order to reconcile those prophecies that seem to contradict each other, as to the character and condition of the *Messiah*, have had recourse to the hypothesis of two *Messiahs*, who are yet to succeed each other; one in a state of humiliation and suffering; the other of glory, splendor, and power. The first, they say, is to proceed from the tribe of Ephraim, who is to fight against Gog, and to be slain by Ammilus, Zech. xii. 10. The second is to be of the tribe of Judah, and lineage of David, who is to conquer and kill Ammilus, and restore the kingdom of Israel, reigning over it in the highest glory and felicity.

Jesus Christ asserts himself the *Messiah*: In St. John iv. 25, the Samaritan woman says to Jesus, *I know that when* Messiah *comes, who is called the* Christ, *he will tell us all things. Jesus answered her, I that speak to thee am he.*

There are several impostors, who have endeavoured to pass for *Messiahs*, as Christ himself predicted. J. Leut, a Dutchman, has written a history of *false Messiahs, De Pseudomessiis*. The first he mentions was one Barcochab, who appeared under the empire of Adrian. The last was rabbi Mordecai, who began to be talked of in 1682. A little before him; viz. in 1666, appeared Sabbethai Sebi, who was taken by the Turks, and turned Mahometan.

MESSIEURS, a French title of honour, or civility, lately introduced into our language; being the plural of *monsieur*, and equivalent to the English sirs, or gentlemen.

The French lawyers always begin their pleadings and harangues with *messieurs*; which word is also frequently repeated in the course of their speeches; on which occasion it answers to our English word *gentlemen*.

The French say, *Messieurs du parlement; du conseil; des comptes*, &c.

MESSUAGE, MESSUAGIUM, in *Law*, a dwelling-house with some land adjoining, assigned for its use.

By the name of *messuage* may a garden, shop, mill, cottage, chamber, cellar, or the like, pass.

In Scotland, *messuage* denotes what we call the *manor-house*; viz. the principal dwelling-house within the barony.

MESUA, called by some *India rose chesnut*, in *Botany*, the name of a genus of plants of the *monadelphia polyandria* class; the characters of which are these: the perianthium is permanent, and consists of four small oval leaves; the flower consists of four large hollow and rounded petals; the stamina are numerous filaments, of the length of the cup; the antheræ are simple; the germen of the pistil is roundish; the style is simple; and the stigma indented in four places. The fruit is a four-cornered single-seeded nut. There is only one species.

MESYMNIUM, a name which the ancients gave to a part of their tragedy, or to certain verses in their tragedies.

The *mesymnium* was a kind of burden, as *Io Paean*; *O Dithyrambe*; *Hymen, O Hymenæe*; or the like; which, when placed at the end of a strophe, was called *ephymnium*; and when inserted in the middle of a strophe, *mesymnium*. See STROPHE, and CHORUS.

METACAL, an Ægyptian weight, used in the weighing of pearls, and consisting either of a carrat and a half, or of two carrats. Sixteen of these carrats make a dram, each of the carrats weighing four grains, and twelve drams an ounce.

METACARPIUS, a small very fleshy muscle, situated obliquely between the large internal annular or transverse ligament of the carpus, and the whole inside of the fourth metacarpal bone.

It is fixed by a small short tendon to the os orbiculare, and to the neighbouring part of the large ligament of the carpus; from thence its fibres run more or less obliquely toward the inside of the fourth metacarpal bone, in the outer edge of which they are inserted. The fibres of this muscle are of unequal lengths, and extend all the way to the articulation of the first phalanx of the little finger, with the fourth metacarpal bone; but they have no manner of relation to that finger. Winslow.

METACARPUS, or METACARPIUM, from μετα, *behind*, and καρπος, *hand*, in *Anatomy*, that part of the hand between the wrist and the fingers. See *Tab. Anat. (Osteol.) fig. 3. n. 10. 10. fig. 7. n. 13.* See CARPUS.

The *metacarpus* consists of four bones, which answer to the four fingers; whereof that which sustains the fore-finger is the biggest and longest. They are all round and oblong, a little convex towards the back of the hand, and concave and plain towards the palm; they are hollow in the middle, and full of marrow; they touch one another only at their extremities, leaving spaces in their middle, in which lie the musculi interossei.

In their upper end there is a sinus, which receives the bones of the wrist; their lower extremity is round, and is received into the sinus of the first bones of the fingers.

The inner part of the *metacarpus* is called the palm, and the outer the back of the hand.

The ancient anatomists reckoned five bones in the *metacarpus*, including that bone which is now looked upon to be the first phalanx of the thumb. These bones are all long, thicker at their extremities than in the middle, and of unequal length and bigness: the two first are sometimes, though very rarely, equal, and the others lessen by degrees from them. Anatomists, in their descriptions, divide each of these bones into a middle and two extremities, or into a basis, body, and head. The bases of them all are angular, and turned toward the carpus, and their head rounded like condyles, and turned towards the fingers. Both extremities are covered with cartilages, and the heads remain for a long time very distinct epiphyses.

The metacarpal bones are moved on the carpus by the muscles called ulnares and radiales, and by all the muscles in general that go to the fingers, as by so many auxiliaries. The number of metacarpal muscles would be increased, if the first phalanx of the thumb were considered as a metacarpial bone. Winslow. See METACARPIUS.

METACARPUS, *fractures of the*. In fractures of the hand or *metacarpus*, the best method of reducing or replacing the bone, is to extend the hand upon a smooth table, and while an assistant holds the whole hand evenly in that posture, the surgeon is to replace the bones; and, when that is carefully and perfectly done, to secure them with a proper bandage. Heister.

METACARPUS, *luxation of the*. The four small bones in the palm of the hand are sometimes luxated from the carpus to which their upper parts are connected; this happens from external violences, not unfrequently, notwithstanding that these bones naturally must much resist such a luxation; for the two carpal bones, which are seated in the middle between the two external ones, cannot be dislocated to either side, as the two external ones, which sustain the first and little fingers, cannot be luxated inwardly, but are very easily driven outward; and each of them may be luxated on the fore or back part of the hand; but whichever of these happens, the particular disorder may be discovered and examined by feeling and inspecting, and the cure may be performed by extending the hand on a flat board or table, and replacing with the thumb whatever of the bones have started from their natural situation. Heister.

METACHORESIS, a word used by Galen to express a recess of a morbid humour from one part of the body to another, a thing very common in many distempers.

METACHRONISM, formed of μετα, and χρονος, *time*, in *Chronology*, an error in computation of time, either on the side of defect or excess.

METACISM, METACISMUS, in *Grammar*, a defect in the pronunciation of the letter *M*.

Isidore represents the *metacism* as a final *m*, followed by a vowel, as *bonum aurum, Bethlehem erat*, &c.

METACOE, in *Botany*, a name given by the people of Guinea to a plant, of which they are very fond, because of its virtues as a balsamic and vulnerary. Its leaves, being bruised and applied to a fresh wound, cure it. They have also another use for it, twisting the dried leaves into a sort of match for their muskets. Phil. Trans. N° 232.

METACONDYLI is used by some authors for the outmost bones, or joints of the fingers, next the nails.

METAGITNION, μετάγειτνιον, in *Chronology*, the second month of the Athenian year. It contained twenty-nine days, and answered to the latter part of our July and beginning of August. The Boeotians called it *Panemus*, and the people of Syracuse, *Carneus*.

It is so called from *Metagitnia*, one of Apollo's festivals kept in it.

METAL, μέταλλον, in *Natural History*, a simple, ponderous, shining, fixed, opake body, that fuses, and becomes fluid, by fire, and by cold coagulates and hardens into a solid mass, capable of being distended under the hammer.

Metal is said to be simple; as it may be affirmed of every the minutest particle of a *metal*, e. g. a grain of gold, that it is gold, or has all the properties of GOLD. *Fusible* by fire; that is, when exposed to a great fire, it dissolves into parts which are easily moveable among themselves, or are in actual motion. See FUSION. *Fixt*, i. e. bearing the fire without flying off in vapours; though it is only up to a certain degree that *metals* are fixed; for, by the large burning-glasses of Meff. Tschirnhausen and Villette, all *metals* are found to evaporate.

Such is the proper idea of *metals*, which is not applicable to any other body in nature; for a diamond, or other stone, though a simple body, is not fusible to the fire, nor capable of being stretched under the hammer. And salt, though dissolvable by fire, is not malleable, but breaks under the hammer.

There are, indeed, certain woods, which yield, in some measure, to the hammer; but then they fall to dust in the fire: and so of the rest.

Authors have commonly reckoned six *metals* in all nature; viz. gold, lead, silver, copper, iron, and tin; to which we may also add a seventh, viz. platina. See the nature, characters, productions, uses, &c. of each, under its proper article.

To these *mercury*, or *quicksilver*, is usually added; but some have objected to the metallic character of MERCURY; though, in reality, it is possessed of the distinguishing properties of *metals*.

The common radical character of *metals* is, that of all known bodies they are the heaviest. By Dr. Halley's experiments, the weight of gold to that of glass is determined to be as 9 to 1; and the weight of tin, the lightest of all *metals*, to that of gold, as 7 to 19; which considerably surpasses the weight of all stones, marbles, gems, and other the most solid bodies, as appears from the tables of specific gravities. Nor is there any body in nature but a *metal* that is one third of the weight of gold: and, therefore, though the natural bodies, from which *metals* differ the least, are earthy and pyritous matters, on account of their solidity and density; yet *metals* and stones are very different; the heaviest stones which are unmetallic being much lighter than the lightest *metals*. A cubic foot of marble weighs 152 pounds, and an equal bulk of tin, the lightest of *metals*, weighs 516 pounds: the difference is much greater when the weight of such a stone is compared with that of gold, a cubic foot of which is 1326 pounds.

The Royal Society furnish us with various experiments of this kind. The weights of the several *metals*, and other solids, they have examined hydrostatically, by weighing them in air, and in water; and the weights of the fluids, by weighing an equal portion of each. By such experiments they find, that taking the same weights of water and gold, the bulk or magnitude of the former, is to the latter, as 1963610 to 100051; consequently, that the weight of gold is to water, nearly, as 19 to 1. See GOLD and *Specific* GRAVITY.

The specific gravity of *metals* can, however, never be very exactly determined, as it varies a little from many causes; first, according to the different heat of the atmosphere, which expands water, and other fluids, infinitely more than it does solid bodies, which it also expands in different degrees; and that unequal diminution of the weight, makes it impossible to assign them a constant proportion, unless the heat be determined with the greatest exactness. Secondly, according to the several degrees of purity in the water, which difference is sometimes found not inconsiderable. Thirdly, according to the different purity of the *metals*; for there is hardly any *metal* found to very pure, but that it may be easily demonstrated to be mixed with some others. Fourthly, according to the different weight of the atmosphere itself; though the effects of its variations be not so considerable as of the rest.

Hence it is that there are, in a manner, as many different accounts of the specific gravities of *metals* as there are authors who have given an account of their experiments on the subject. However, except the *metals* be of a very great impurity, the sum of all the variations, resulting from all these causes, is not sufficient to hinder any *metal* from being certainly distinguished from any other *metal*, by its specific gravity.

Slight variations in hydrostatical experiments are indeed neither few things, nor are they by any means avoidable, either in making these or other experiments of affinity to them. By way of proof to such as may distrust this, from their never having made such experiments themselves, two very eminent testimonies may be produced. That most industrious and diligent mathematician Merfennus candidly acknowledges, that when he has occasion to mention the experiments of the learned Ghetaldus, and of the accurate French engineer Monsieur Petit, with his own, there will be often a variety of weight of some few grains; but he says, it is only like the variety of astronomical observations, which do almost always differ also by a few minutes or seconds; and to this he afterwards adds, that he expected not an exact uniformity between the observations of Ghetaldus, &c. already made, and the trials of any new experimenter, who would go through the work again. And our famous experimenter the lord Verulam confesses, that it is not to be doubted, but that many of the bodies which he has set down in the table he has given, of their dimensions and weights, differ in the same species or denomination, some being heavier than others, and that therefore there is some contingency in the affair; so that it is not necessary that the individuals he made his trials upon should be exact standards of the weight of their respective species, or should, which makes directly to our present purpose, agree altogether to a tittle with the experiments of other men. Boyle, Hydrost. Experim. in Prof. But this scarce evitable imperfection of hydrostatical experiments does not hinder, but that by their help we may make good estimates of the weights and bulks of very many bodies; and these estimates will be found not only preferable to those that can be made of the same bodies by geometrical instruments, but accurate enough to be very useful on a great number and variety of occasions.

Besides the fusibility, malleability, fixedness in the fire, and gravity pertaining to *metals*, in a peculiar degree, as such, and distinguishing them from other substances, they possess also other properties, which we shall here enumerate. Thus, the opacity of *metals* is much greater than that of any unmetallic substances: this results from their density: and these two properties produce a third, peculiar also to *metals*, viz. a capacity of reflecting infinitely more light than any other body, to which they owe their distinguishing lustre, called the metallic lustre: hence *metals*, whose surfaces are polished, form mirrors, representing the images of bodies more clearly than any other matter. It is observed also, that although the several metallic substances differ considerably in hardness and fusibility, yet, in general, they are less hard and less fusible than some earths. Further, *metals* cannot unite with any earthy substance, not even with their own earths, when these are deprived of their metallic flux: hence, when they are melted, they run, as much as possible, into globes; and a *metal*, in a state of fusion, always endeavours to acquire a convex or spherical form. Moreover, all *metals* are, in general, soluble by all acids; and form neutral salts with metallic bases: but the affinity of *metals* to acids is less than that of absorbent earths and alkaline salts; and, therefore, any *metal* may be separated from any acid by these earthy and saline alkalies.

Alkaline salts are also capable of acting upon all metallic substances, and of keeping them dissolved by proper management. *Metals* may, in general, be united with sulphur and liver of sulphur; but they have less affinity with sulphur than with acids, so that sulphur may be separated from them by acids. All *metals* may, under certain restrictions, be united with each other, by which means they form different alloys, possessing peculiar properties. See ALLAY and AMALGAMATION. They have also a strong affinity with the inflammable principles, and are capable of receiving it superabundantly. Lastly, oily substances seem to be capable of acting upon all *metals*.

These several properties agree, in general, to all metallic substances: but, besides the properties peculiar to each *metal*, some properties are common to a certain number of them: and hence they have been divided into several classes. See *Species of* METALS.

However, though all *metals* possess the properties above enumerated, we are by no means to conclude, that they possess them in the same degree. The order, says the ingenious author of the Dictionary of Chemistry, in which *metals*, compared with each other, possess most eminently their principal properties, is as follows, beginning always with that *metal* in which the property is most considerable. 1. Specific gravity and density. Gold, platina,

platina, mercury, lead, silver, copper, iron, and tin. 2. Opacity. If *metals* differ in this reſpect, the ſame order will ſerve for opacity as for denſity. 3. *Metallic* luſtre or brilliancy. Platina, iron, or rather ſteel, ſilver, gold, copper, tin, lead. It is obſerved, however, by the tranſlator, that, if platina, the reflecting power of which cannot eaſily be determined, be excluded, their reflecting powers will be more nearly in the following order: ſilver, quickſilver, tin, gold, iron, copper, lead. 4. Ductility. Gold, ſilver, copper, iron, tin, lead. The ductility of mercury and platina are not yet determined. 5. Hardneſs. Iron, platina, copper, ſilver, gold, tin, and lead. 6. Tenacity. Gold, iron, copper, ſilver, tin, lead. The tenacity of mercury is not known, and that of platina, though probably very conſiderable, not determined. 7. Fuſibility. Mercury, tin, lead, ſilver, gold, copper, iron, and laſtly platina. See *Table of* AFFINITY.

METALS, *as to the origin and formation of*, various are the ſentiments of philoſophers, ancient and modern. M. Tournefort is of opinion, that *metals*, as well as all other minerals, have their origin from ſeeds, like plants; and that they have veſſels with juices circulating in them, &c. See STONE.

Plato will have the cauſe of *metals* to be a humid vapour, incloſed in the bowels of the earth, which, being variouſly intermixed with parts of the earth, produces various metals. Plotin maintains ſulphur to be the father of *metals*; and an oleaginous viſcous humour, the mother. Lidgat endeavours to prove all *metals* generated by a ſubterranean fire; urging, among other reaſons, that many *metals*, when taken out of the earth, are exceedingly hot. Du Hamel ſhews, that *metals* do not take their riſe either from any vaporous exhalation, or from water, or from earth; but are generated of mercury, ſulphur, and ſalt. He adds, that *metals* take their matter and weight from the mercury they contain, and their tincture and form from the ſulphur.

The ſame author owns the firſt rudiment of a *metal* to be a ſaline ſubſtance ſwimming in water, which water is by little and little carried off. By how much the terreſtrial parts are more exquiſitely mixed with the aqueous or humid, by ſo much is the *metal* more heavy and firm, as having fewer and ſmaller pores. Hence its ductility; for its parts being extremely ſmall, denſe, and complicated, may be drawn out into a very ſpacious ſurface: on which account it is, that gold exceeds all other *metals* both in weight and ductility. Hence alſo its fixity, its parts being too cloſe and denſe to be exhaled. The water defends the earth from being burnt, and the earth the water from flying off; neither forſakes the other, but each is bound in an indiſſoluble knot. The moiſture gives ductility, the earth ſolidity. Where the mixture is leſs perfect, whether the earth or the water prevail, the *metal* will neither have ſo much weight, as having larger pores; nor will it bear the fire ſo well. For if the earth prevail, as in iron, or the water, as in lead; heat will ſet the one at liberty from the other; the moiſture evaporates, and the earth is reduced into ſcoria, &c.

Dr. Woodward maintains, that all *metals*, now found in the ſtrata of the earth, owe their preſent condition to the deluge; when he alſo imagines the preſent ſtrata of ſtone, earth, marble, &c. were formed.

The *metallic* and mineral matter, now found in the perpendicular intervals or fiſſures of the ſeveral ſtrata, whereof the earth is compoſed, was, according to him, at the time of the deluge, lodged in the bodies of thoſe ſtrata; and has been brought thence, and tranſmitted into theſe intervals ſince that time; the intervals themſelves not exiſting till the ſtrata were formed, and broken again, to let the water from the earth.

Now the water, which he imagines is conſtantly aſcending from the great abyſs towards the ſurface of the earth, continually pervading the ſtrata, detaches out of their pores and interſtices ſuch *metallic* and mineral corpuſcles as it finds looſe in its way, carrying them along with it to the perpendicular intervals, where having a freer paſſage than before, it deſerts them, and leaves them in thoſe intervals. And this he takes to be the way in which all *metals*, now found in thoſe places, were brought thither, and ſtill continue to increaſe.

Thoſe in the ſtrata, however, he obſerves, do not, nor can increaſe; but, on the contrary, are continually leſſened and diminiſhed, by ſo much as has been conveyed into the perpendicular intervals, and brought forth of the ſurface of the earth by ſprings and exhalations from the abyſs, &c.

The ſame ingenious author complains of the great uncertainty and inconſtancy in the mineral and *metallic* kingdom; neither colour, figure, nor ſituation in the earth, being to be depended on, ſo as to allow any poſitive judgment to be formed from them. A pyrites or mareaſite, for inſtance, ſhall have the colour and brightneſs of gold or ſilver, and yet afford nothing but a little vitriol and ſulphur; while what is but a pebble in appearance ſhall have a mixture of a valuable *metal* in it. It is common too to find the ſame *metal* ſhot into a great number of different forms, as well as to find different kinds of *metal* of the ſame form. And as to their place in the earth, there is the ſame uncertainty; they being ſometimes found in the perpendicular fiſſures or intervals of the ſtrata, ſometimes interſperſed in the bodies of the ſtrata, and ſometimes in both. The ſame *metals* are alſo placed indifferently in all kinds of terreſtrial matter, or in ſtrata of very different natures. They are frequently intermixed with each other, ſo that it is a rare thing to find any of them pure and ſimple; but copper and iron ſhall often be in the ſame maſs, as alſo gold and copper, ſilver and lead, tin and lead; nay, ſometimes all ſix together in the ſame lump.

The French chemiſts have been very curious in their enquiries into the nature and production of *metals*. M. Geoffroy, from a mixture of ſulphur with a vitriolic ſalt, and an argillous earth, brought an iron, which he maintained to be a new production, or a compoſition reſulting from the aſſemblage of certain principles which exiſted ſeparately in the ingredients that formed the *metal*; in a word, that it was an artificial iron. And obſerving that there were parcels of this *metal* in the coloured aſhes of plants, and of moſt other inflammable ſubſtances, he concluded that it might be formed there alſo by the union of the ſame three principles.

This was oppoſed by M. Lemery the younger, who maintained that the iron contained in the aſhes of plants was not formed there by calcination, but was really exiſtent in the plants themſelves; being raiſed in their veſſels along with the juices of the earth; and further, that all the ingredients whereof M. Geoffroy's artificial iron was formed, do really contain iron in themſelves, either in ſmaller or larger quantities; not the argilla only, where the iron is eaſily diſcovered by an animated knife; nor the oil of vitriol, which is drawn from a mineral, the ground whereof is iron; but alſo linſeed-oil, whereof M. Geoffroy's ſulphur was made; and even that of turpentine, ſweet almonds, &c. relating withal the operations whereby each of thoſe oils may be reduced to an earth wherein is iron.

To this it was anſwered, that in what manner ſoever iron be procured from the ſeveral ingredients ſeparately, there will be ſtill found infinitely leſs in them, than when mixed; and that, of conſequence, the mixture produces iron; that as for oils, it is evident they are not ſimple ſubſtances, but are compoſed of an earth, an acid, and a ſulphureous or inflammable part; which are the three preciſe principles required for the formation of iron: ſo that, according to all appearance, it is of an aſſemblage of thoſe ſulphurs, ſalts, and earth, in the oil, that the iron is formed by calcination; and therefore that the means uſed to the iron in the ingredients, are the very ſame with thoſe by which it is compoſed. See IRON.

Hence alſo appears, that vegetable matters contain the principles of minerals. But M. Geoffroy goes farther; and to ſupport his doctrine of the production of *metals*, he undertakes to prove, that the principles of vegetables, and thoſe of minerals, are eſſentially the ſame; and that one may reſolve, and with eaſe, decompound minerals by ſeparating their principles, and compound them again by ſubſtituting principles taken from vegetables in lieu of thoſe taken away.

To clear this point, he examines and compares the principles of mineral and vegetable ſalts. The principal in the mineral claſs are nitre, ſea-ſalt, and vitriol; all which ſalts we find in plants. The eſſential ſalt of the parietaria is wholly nitrous, and melts on the coals like ſalt-petre. The fixt ſalts of the cardous benedictus, abſinthium, kali, &c. contain a great deal of ſea-ſalt, which cryſtallizes in cubes, and decrepitates on the coals. Add, that the greateſt part of the fixt ſalts of plants, calcined to a certain degree, yield a ſtrong ſmell of ſulphur; which can proceed from nothing but a vitriolic ſalt, rarefied and volatilized by the oil of the plant. By theſe ſalts we may be able to judge of all the other ſalts of plants; for the volatile ſalts are nothing elſe but fixt ſalts diſengaged from the groſſeſt part of their earth, and joined with parts of oil.

Farther, there is ſcarce any reaſon to doubt, that the acid juices, drawn from vegetables, are of the ſame nature with the mineral acids; with this only difference, that the acids of plants have been extremely rarefied by fermentation, and united ſo cloſely with ſulphurs, that it is not without a great deal of difficulty that they are ſeparated.

Thus, diſtilled vinegar, which we make no ſcruple of ranking among the vitriolic acids, does only differ from ſpirit of ſulphur, ſpirit of vitriol, or even the cauſtic oil

of vitriol, in that the acids in the vinegar are diffused among a great deal of phlegm, and ſtrongly united to a great deal of oil, which yet may be ſeparated. By diſſolving copper in the acid of vinegar, ſeparated as much as poſſible from its oil, there are formed cryſtals, like in figure to thoſe of blue vitriol. From all which it appears, that the ſalts of plants do not differ eſſentially from thoſe of minerals.

As for ſulphurs, the inflammable or ſulphureous principle is the ſame in vegetables as in minerals. And M. Geoffroy even ſhews, that the principle of inflammability in common ſulphur is the ſame with that which renders the fat of animals, the oils and reſins of plants, and the bitumens of the earth, inflammable. To which he adds, that this ſame ſulphureous principle is not only likewiſe found in metallic ſubſtances, but that it is this which gives them their fuſibility, ductility, and metalline forms. Thus antimony, which is a ſubſtance approaching the neareſt of any to a *metal*, is little elſe but a burning ſulphur. By exhaling this, it loſes its *metallic* form, and turns to a kind of grey aſhes, which, being melted, inſtead of *metal*, becomes glaſs; and by melting this over again, and adding to it ſome inflammable matter, again it returns into a regulus. See the ſequel of this article, and MINERAL.

Stahl maintains, that *metals* have the ſame origin with the earth itſelf, and that theſe and the *metallic* veins that contain them, were formed at the firſt creation of the earth. However, there is reaſon to believe, that *metals* and their mines are continually formed in the bowels of the earth by various proceſſes, ſuch as earthquakes, according to the ſyſtem of Lomonoſow, &c. adapted to this purpoſe.

METALS, *as to the ſpecies of*, there are four which the chemiſts call *imperfect*, becauſe their principles are not bound ſo faſt together, but that the force of a common fire deſtroys them; ſo that by its continued action they are changed into an earth deprived of all the characteriſtic properties of *metals*: theſe are, iron, copper, lead, and tin; the others, which are ductile or malleable, and which alſo remain fixed in the moſt violent and long continued fire, without diminution of weight, or other ſenſible alteration, are gold, ſilver, and platina: theſe, therefore, are called *perfect metals*.

The *metallic* ſubſtances, which, as well as the imperfect *metals*, loſe their *metallic* properties by expoſure to fire, but which alſo have no ductility, or fixity, are diſtinguiſhed from the others by the name of *ſemi-metals*. Of this claſs are five; regulus of antimony, biſmuth, zinc, regulus of cobalt, and regulus of arſenic; to which ſome have added nickel. Laſtly, mercury, which has all the general properties of *metals*, makes a claſs ſeparate from the others; becauſe in purity and gravity it is ſimilar to the perfect *metals*, and in volatility to the *ſemi-metals*. Its fuſibility alſo ſo far ſurpaſſes that of any other *metallic* matter, that it is ſufficient to diſtinguiſh it from all, and to give it a diſtinct claſs. Of the fourteen *metallic* ſubſtances above enumerated, three were unknown to the ancients, viz. platina, regulus of cobalt, and nickel.

In the firſt four, it is eaſy to ſee the principle of inflammability: they become all fuſible by the addition of ſaltpetre, either in a greater or leſs degree. But the principle is more conſpicuous ſtill in the duſt or ſmall filings of the *metals* let fall in the flame of a candle, than in the lump.

In gold and ſilver, the ſulphureous principle is not ſo obvious. No heat, but that of the ſun collected into a focus, is able to decompound them; but, no doubt, even theſe have the ſame principles with the other *metals*, though they are not ſo eaſily ſeen. In gold, as well as in the imperfect *metals*, the baſis is an earth capable of vitrification, as appears by the glaſs remaining after the calcination of gold in a burning-glaſs: and there is reaſon to believe, that the greateſt part of what is exhaled in ſmoke during the operation, is the ſulphureous principle mixed with ſalts.

As to ſilver, there is ſomething in it extremely various. When purified with antimony, it vitrifies by the burning-glaſs; but if purified with lead, it leaves nothing behind it but grey aſhes. The baſis of this *metal* is doubtleſs an earth capable of vitrification; and what exhales in ſmoke, is apparently a mixture of ſulphur, ſalts, and a little earth, volatilized by the fire.

From all theſe, and many more obſervations of the ſame kind, M. Geoffroy ventures to draw the following concluſions; that the ſubſtances whereof *metals* are compoſed, do not differ eſſentially from thoſe which compoſe vegetables: that the imperfect *metals* are compoſed of a ſulphur, vitriolic ſalt, and vitrifiable earth: that this ſulphureous principle is more or leſs ſtrongly joined with the other principles; very ſtrongly in gold and in ſilver, leſs in antimony, and very little in mineral ſulphur; that the principle of inflammability may be ſeparated from *metallic* ſubſtances, either by culinary fire, or by the ſun: that the *metal*, thus deſpoiled of its principle, is converted into aſhes; and that theſe aſhes, purſued farther with a violent fire, vitrify; and that ſuch aſhes or glaſſes, by the application of ſome inflammable matter, again reſume the *metallic* form they had loſt: that it is by theſe means fluxed-oil turns clay into iron: that, if we knew all the other *metallic* earths, they might likewiſe be immediately converted into *metals*, by the projection of ſome proper inflammable matter: that the ſaline and earthy parts, found in proper vitriol, furniſh the earthy vitrifiable part, which makes the baſis or ground of iron; and that it receives the *metallic* form from the ſulphureous principle of the oil: that the iron, found in the aſhes of plants, was produced there in the ſame manner; and that it is a compoſition of the vitrifiable earth of the plants, the acid of thoſe plants, and their oily or inflammable principle. But it has been ſufficiently proved by many writers, that by Mr. Geoffroy's experiments, iron is only reduced or revived, but is not produced.

The ſame author, the better to aſcertain the conſtituent parts of *metals*, made a great number of experiments on them with the duke of Orleans's large burning-glaſs: the reſult whereof ſalls in with, and confirms, the doctrine laid down above. From thoſe experiments, he gathers, that the four *metals*, which we call *imperfect*; viz. iron, copper, tin, and lead, are compoſed of a ſulphur, or oily ſubſtance, capable of burning, and a *metallic* earth, capable of vitrification. That from this ſulphur proceed the opacity, brightneſs, and malleability of a *metal*. That this *metallic* ſulphur does not appear at all different from the oil or ſulphur of vegetables, or even that of animals; and that it is the ſame in mercury, as in the four imperfect *metals*. That theſe four *metals* have for their baſis an earth ſuſceptible of vitrification; that this earth is different in each of the four *metals*, in that it vitrifies differently in each; and that on this difference in vitrifying, depends the difference of *metals*.

The learned Boerhaave, after an accurate ſurvey of the ſeveral *metals*, their characters, properties, preparations, uſes, &c. draws the following concluſions concerning the general nature of *metals*. 1. That which diſtinguiſhes *metals* from all other bodies, as well as from each other, is their heavineſs; though every *metal* has its peculiar weight, which no art is able to imitate, and which depends, as Helmont and the chemiſts expreſs it, on the ſtraiter homogenity of their parts. Now, the later philoſophers have proved, that all corporeal magnitude has juſt ſo much reality in it, as it has weight; and therefore, if you have found the heavineſs of any *metal*, you have, at the ſame time, found its corporeity. Sir Iſaac Newton, treating of gravity, and Huygens of the pendulum, ſhew, that weight and reality are correſpondent. 2. The *metals* appear to be ſimple, yet they are really compounds. Their component principles, according to the ancients, are ſulphur and mercury; to which ſome of the moderns have added ſalt; but it is certain, ſalt is no conſtituent part, or ingredient, of *metals*, but rather ſomething external adhering to them. All *metals* conſiſt of two parts or principles; mercury, as the baſis, or matter; and ſulphur, as the binder, or cement; the firſt, the ſubſtratum, or *metallic* matter; and the ſecond, that which renders it fixed and malleable. The mercury, it is to be noted, is the ſame with our quickſilver, only defecate, and clear of any heterogeneous matter; whereas the common quickſilver is always mixed. As to the ſulphur, it is not the vulgar foſſile ſulphur, but a peculiar ſort of matter ſpecifically denominated *ſulphur of metals*, concluded by ſome of our lateſt and beſt chemiſts, particularly M. Homberg, to be fire; which, being mixed with the mercury, fixes it, and, according to the different degrees of its union and cohеſion therewith, produces different *metals*.

This doctrine of the compoſition of *metals* is confirmed by an experiment of Mr. Boyle, who tells us, that, after having retained mercury a long time in a moderate fire, he took a piece of gold out of it, which, it was apparent, was not in the mercury before it was expoſed to the fire. M. Homberg alſo has an experiment to the ſame effect; from which he concludes, that gold conſiſts of a ſulphureous igneous part, and a heavy mercurial part fixed thereby; and that, upon taking away the ſulphureous or fiery part, the gold muſt be converted into fluid mercury.

3. All *metals* muſt firſt be mercury, before they be gold; and the thing ſuperadded to common mercury, whereby it is prevented from becoming gold, is a ſharp volatile body, which, when heated, becomes corroſive, and emits fumes; which are the true properties of the foſſile ſulphur.

4. If any *metal*, or other body, could be found, that only differed from gold in its wanting weight, it were impoſſible ever to make gold of it; and, on the contrary, if a

body could be had, that is as heavy as gold, all the other properties, as colour, fixity, ductility, &c. might eaſily be added. And hence the more knowing among the alchemiſts hold the primary matter of gold to be quickſilver; which, ſay they, is gold at heart, as coming neareſt to gold in point of ſpecific gravity. Only there is a corroſive body, i. e. ſulphur, adhering to it, which if it were ſeparated, you would have gold; or, if it were only inverted, ſilver.

And accordingly, on ſuch principles, whoever would make gold out of any other foreign matter, muſt remember, that the more his matter differs from mercury in weight, &c. the leſs gold it will make. See PHILOSOPHER's *ſtone*.

5. Therefore *metals* are tranſmutable into one another: for, if mercury be the common matter of all *metals*, and if all the difference lie in the fixing ſpirit or ſulphur, which, as it is leſs or more ſubtile or pure, conſtitutes this or that *metal*, it is no way improbable that they ſhould be tranſmuted by a purer fixing ſulphur taking place of a corroſive one, and fixing the matter into a more perfect *metal*.

6. The pureſt *metals* reſult from the pureſt and moſt defecate mercury, and the ſmalleſt quantity of the ſubtileſt ſulphur. Hence, mercury of gold is heavier than common mercury, and has always ſome impure part that is lighter than gold; and could that be taken away, and the fixing ſpirit be added, it would become heavier than gold.

7. The imperfect *metals* conſiſt of impure mercury, and imperfect ſulphur, with ſome other valuable heterogeneous matter in it: this, fuſed by the fire, emits a fume, which whitens copper; after which, the ſulphur exhales yet farther. The reality of ſuch a third matter is evinced by this circumſtance, that all the baſer *metals* are reſolvable not only into mercury and ſulphur, but alſo into feces or fordes, which are lighter and more earthy than either of the other, and accordingly ſwim therein.

8. Upon the whole, it appears, that in the three nobler *metals*, gold, mercury, and ſilver, it is principally the greater or leſs proportion of the ſulphur to the mercury that determines them to be gold, mercury, or ſilver; that it is by this proportion thoſe ſeveral *metals* are defined and denominated; and that, from this difference of proportion, flow all the ſpecific differences of colour, weight, fixity, ductility, volatility, fuſibility, ſolubility, falubrity, &c.

9. That in the other baſer *metals*, beſides this different proportion of the two principles, there intervenes another cauſe of diverſity; viz. a third principle, or matter of an earthy kind, and very different from either of the reſt; which, adhering to the pure elemental ſulphur, corrupts and adulterates, and variouſly modifies it; and from the different circumſtances of this third principle, conſidered along with thoſe of the ſulphur itſelf, reſult the ſpecific differences of the more imperfect *metals*, as to weight, colour, and their other qualities.

The ſyſtem of *metallization*, which ſuppoſed ſalt, ſulphur, and mercury, to be the conſtituent elements of *metals*, ſubſiſted under various modifications, till Beecher evinced, that theſe three principles are in themſelves compound bodies, and, therefore, could not be properly elements of bodies; and, purſuing his reflexions on this ſubject, he was led to conſider *metals*, and all bodies of the ſame nature, as compounded of three ſubſtances, which he called earths. The firſt is the ſaline or vitrifiable earth; the ſecond is the fat or inflammable earth; and the third the mercurial or volatile earth. According to his theory, theſe three earths enter into the compoſition of all *metals*; the perfection of which depends on their more perfect combination, and their difference on the degree in which one of theſe principles prevails over the others, and the various proportions in which they are combined in various *metals*. Beecher has endeavoured to demonſtrate the exiſtence of theſe three principles by reaſoning and experiment. In proof of the exiſtence of a vitrifiable earth in *metals*, he alleges their calcination by fire, gold and ſilver excepted, or their tranſmutation into an earth or aſhes, which farther urged by fire is changed into glaſs. The inflammable principle or phlogiſton of *metals*, is neceſſary to correct and temper the dryneſs of the former, and is generally admitted. The mercurial earth, according to him, is the moſt eſſential principle of *metals*, and ſerves to give them their *metallic* form. The other two, *metals* poſſeſs in common with ſtones, vegetables, &c. but this mercurial earth, joined to the two others, gives *metals* that ductility which is peculiar to them, and which conſtitutes their *metallic* nature. This theory has been adopted and illuſtrated by Stahl, and many other chemiſts; who maintain, that the mercurial principle above mentioned exiſts copiouſly in mercury; that it alſo exiſts in marine acid, to which it gives its ſpecific character; and that by extracting it from this acid, or from any other body containing it copiouſly, and *combining it with ſimple earths, theſe may acquire a metallic* character, and be rendered capable of receiving phlogiſton, and of being completely *metallized*. Thoſe *metals*, in which the mercurial earth exiſts moſt copiouſly and ſenſibly, are mercury, ſilver, lead, and arſenic. It has been urged as a ſtrong preſumption in favour of the exiſtence of this third principle in *metals*, that no method has yet been diſcovered of producing *metals*, by merely combining phlogiſton with ſome matter which is certainly known to be ſimple earth. Beſides, it is not eaſy to conceive, how from only two certain principles ſo many very different compounds, as the ſeveral *metallic* ſubſtances are, ſhould reſult. On the other hand, the exiſtence of this mercurial principle is only probable, and there are many reaſons to doubt of it. It is agreed, that marine acid, mercury, arſenic, and the other ſubſtances in which the mercurial earth is ſuppoſed to abound, are very volatile; and therefore, that this principle muſt likewiſe be volatile: conſequently, when *metals* are decompoſed by combuſtion, or by detonation with nitre, a conſiderable part of this volatile principle muſt be diſſipated. Hence it muſt be impoſſible to reſtabliſh the calxes of *metals*, without recombining not only their loſt phlogiſton, but alſo their loſt mercurial earth. But it is well known, that by addition of phlogiſton alone theſe calxes may be metallified, and that no mercurial principle is neceſſary. Henkel maintains, that the mercurial earth is not a diſtinct ſubſtance, but conſiſts only in a beginning of union of phlogiſton with earth, or in a diſpoſition which an earth has of uniting intimately with the inflammable principle. Other very conſiderable chemiſts have alſo been of opinion, that two principles, viz. earth and phlogiſton, are ſufficient to form a *metal*, and have rejected the mercurial principle of Beecher. The ſolidity, the conſiſtence, and eſpecially the gravity, which *metals* poſſeſs in a degree ſuperior to all other bodies, will not allow us to doubt, that the earthy element, of which theſe are the characteriſtic properties, enters largely into their compoſition, and makes their baſis. And the facility with which they combine with almoſt all inflammable matters, and with all thoſe which have great affinity with phlogiſton, ſuch as acids, joined to their incapacity of being allayed with meagre matters that are purely earthy or watery, which have no diſpoſition to unite with phlogiſton, furniſh alſo very ſtrong reaſons for believing, that the inflammable principle enters largely into the compoſition of *metals*. But the cleareſt and moſt ſatisfactory demonſtration of the exiſtence of this principle, is the combuſtibility of all *metals* capable of decompoſition in this way, and their ſubſequent reduction with all their properties, by the re-union of the inflammable principle. Beſides, the deſtructible *metals* perfectly reſemble, in the ſtate of COMBUSTION, all bodies containing phlogiſton. When expoſed to fire in cloſe veſſels, they become red-hot, melt or ſublime, according to their nature, but undergo no other alteration. But imperfect *metals*, expoſed to fire, with acceſs of air, burn more or leſs ſenſibly, as their inflammable principle is more or leſs abundant, or more or leſs combined. Beſides, the phlogiſton of *metals* is conſumed by DEFLAGRATION with nitre more quickly and more completely than by ordinary calcination or combuſtion; and nitre is alkaliſed by theſe *metallic* detonations in the ſame manner as in its detonation by coals: and farther, imperfect *metals*, treated with the vitriolic and nitrous acids, which have an affinity with phlogiſton, are more or leſs deprived of their inflammable principle. It is alſo evident, that phlogiſton is one of the conſtituent parts of *metals*, becauſe their eſſential properties are altered in proportion to the quantity of it taken from them: thus, the reſiduum of *metallic* matters, after calcination, departs from the *metallic* character, and approaches to the nature of mere earth. The opacity, brilliancy, ductility, gravity, fuſibility, volatility, and all the properties by which *metallic* ſubſtances differ from ſimple earths, are diminiſhed, or entirely diſappear, by taking from them their inflammable principle; ſo that after the utmoſt calcination they reſemble mere earth: which can no longer be combined with acids or with *metals*, but are capable of uniting with purer earths. In this ſtate they are called calces, or *metallic* earths. See CALX.

Another proof of the exiſtence of the inflammable principle in *metals*, is deduced from the reduction of *metallic* calces into *metal*, by the addition of phlogiſton alone. Thus, if the earth of a *metal* be mixed with any inflammable matter, which either is, or can be changed into the ſtate of coal, together with ſome ſalt capable of facilitating fuſion, but which, from its quantity or quality, is incapable of receiving the inflammable principle; and if the whole be put into a crucible, and the fuſion promoted by a fire gradually raiſed, then an effervescence will happen, accompanied with a hiſſing noiſe, which continues for a certain time, during which the fire is not to be increaſed: afterwards, when the whole has been well fuſed, and the crucible taken from the fire and cooled,

we shall find at the bottom, upon breaking it, the *metal*, the earth of which was employed for the operation, poſſeſſed of all the properties which it had before CALCINATION and REDUCTION. This tranſformation of an earthy ſubſtance into a *metal*, is ſolely cauſed by the phlogiſton paſſing from the inflammable matter to the *metallic* earth; becauſe, in whatever manner, and with whatever ſubſtance, *metallic* earths be treated, they cannot ever be reduced into *metals* without a concurrence of ſome ſubſtance containing phlogiſton; and the nature of this ſubſtance is indifferent, becauſe the inflammable principle is the ſame in all bodies containing it; and farther, if, after the operation, the ſubſtance furniſhing the phlogiſton be examined, we ſhall find that it has loſt as much of that principle as the *metallic* earth has received. Theſe and other facts that might be recited concerning the decompoſition and the recompoſition, or REVIVIFICATION of *metals*, prove inconteſtibly, that they are all compoſed of EARTH and PHLOGISTON. And, in general, if we reflect on the eſſential properties of the earthy and inflammable principles, we ſhall eaſily perceive that theſe properties, being combined and modified by each other, without the ſaline principle of ſome chemiſts, perhaps without the mercurial principle of Beecher, ought to produce the properties of *metals*. Dict. Chem. art. *Metals*. Mem. Acad. Par. 1709. See MINERAL.

The principle which is combined with *metals*, during their CALCINATION, and which augments their weight, ſeems to be nothing more than the pureſt portion of the air we breathe, which, in this operation, paſſes from a ſtate of expanſibility to a ſtate of ſolidity.

METALS *for ſpeculæ*. See SPECULUM.

METALS, *colours from*. As metals have a ſtrong texture in their metalline form, ſo they preſerve their natural colours durably, unleſs corroded or diſſolved by particular menſtruums, after which their ſolutions ſtrike particular durable colours, or afford the ſtrongeſt ſtains.

Iron diſſolved in ſtale ſmall beer gives the beautiful yellow and different ſhades of buff-colour, uſed in printing linens and cottons, &c. When ſublimed with ſal ammoniac it alſo affords a yellow; and the common iron-moulds made by ink are owing to the iron diſſolved in the copperas of which ink is made.

Copper melted with zinc appears of a gold-colour; diſſolved in aqua fortis, it affords a beautiful green; and in any alkali, a beautiful blue. And theſe ſolutions may be reduced to dry colours by cryſtallization or evaporation; and the ſame *metal*, precipitated out of aqua fortis with common ſalts, gives the turquoiſe-colour to white glaſs.

Tin, a white or colourleſs *metal*, affords a light blue colour, when fluxed with antimony and nitre. The ſame *metal* is neceſſary in ſtriking the ſcarlet-dye, with aqua fortis and cochineal; and its calx, by ſtrong infuſion, turns to a glaſs of an opal colour.

Lead, corroded by the fumes of vinegar, gives the fine white cerus; burnt in a ſtrong naked fire, it becomes the ſtrong red-lead or minium; and melted into a glaſs with ſand, is of the hyacinth-colour. Shaw's Lectures, p. 171.

Silver being diſſolved in aqua fortis, if chalk be put to the ſolution, turns of a beautiful purple or amethyſt-colour; and its own ſolution, though pale as water, durably ſtains the nails, ſkin, or hair, brown or black.

Quickſilver mixed with brimſtone makes a black maſs, and thus, by ſublimation, affords the beautiful red pigment, called cinnabar, or vermilion; and the ſolution of quickſilver being precipitated with common ſalt, yields a ſnow-white powder, which alſo turns black by being mixed with ſulphur.

Gold, diſſolved in aqua regia, affords a fine yellow liquor, which ſtains animal ſubſtances beautifully purple; and if the ſolution be ſufficiently weakened with water, and mixed with a ſolution of tin, a fine red or purple powder may be procured, very uſeful for ſtaining of glaſs and paſtes to a beautiful red.

It appears from the experiments of Sir Iſaac Newton, relating to the changes of colour that take place in pellucid colourleſs ſubſtances, that the leſs refrangible COLOURS are exhibited by the greater thickneſs of air, water, and glaſs; and that as the thickneſs of thoſe ſubſtances is diminiſhed, they reflect the more refrangible colours. Hence he infers, that nothing more is requiſite for producing all the colours of natural bodies, than the ſeveral ſizes and denſities of their particles. Accordingly he attributes the colours of permanently coloured bodies to the ſame cauſe by which they were produced in colourleſs ſubſtances, viz. to the various thickneſſes of their component particles. But no experiments were made on permanently coloured bodies, in order to eſtabliſh the truth of Sir Iſaac Newton's opinion, till the ingenious Mr. Delaval directed his attention to this ſubject. From obſerving the circumſtances above recited, and more largely illuſtrated under the article COLOURS, it appeared to him, that, if permanently coloured bodies are ſubject to the ſame laws as tranſparent colourleſs ſubſtances are, all ſuch permanently coloured bodies, whenever the ſize of their particles is diminiſhed, ſhould undergo a change of colour, by aſcending from the leſs refrangible to the more refrangible colours; and that ſuch bodies, when the ſize of their particles is augmented, ſhould undergo a contrary change, their colours in this caſe deſcending from the more refrangible to the leſs refrangible colours. In order to confirm this concluſion, he made a great variety of experiments with vegetable, animal, and mineral ſubjects, whereby the ſize of their particles, upon which their colours depend, might be diminiſhed or increaſed. The methods which he uſed, in order to diminiſh the ſize of the particles of thoſe bodies which were the ſubject of enquiry, were by diſſolving, attenuating, &c. by means of chemical ſolvents, heat, putrefaction, dilution, &c. The contrary effects were brought about by ſuch means as are known to condenſe, incraſſate, or unite the particles of bodies into larger maſſes, as by coagulation, precipitation, evaporation, by diminiſhing the force of the ſolvents, &c. The *metals* afforded him numerous inſtances in confirmation of the doctrine above explained; for almoſt every operation, to which they are ſubject, exhibits a change of colour correſponding to this doctrine. This is particularly the caſe with regard to the imperfect *metals*; for every change of their texture is accompanied by a correſpondent change of colour. We can only enumerate ſome of the principal reſults which Mr. Delaval obtained from a great number of well conducted experiments. Thus, the green vitriol of iron is changed, in proportion as it is deprived of its ſolvent part, by expoſing it to a ſtrong heat, &c. to yellow, orange, red, and purple; and by a contrary proceſs, viz. by a farther attenuation, by means of the phlogiſticated lixivium, in the proceſs of *Pruſſian* BLUE, &c. the colour of the iron aſcends from green to blue; ſo that all the primary colours are produced from the ſame metal, in proportion as its particles are attenuated or incraſſated. It appears likewiſe, that when iron is divided into very ſmall parts by means of a large quantity of glaſs, and by a violent heat, its colour is blue; but in proportion as it is leſs divided, by the mixture of a ſmaller quantity of glaſs, or the application of leſs heat, its colours are green, yellow, and red. From iron diſſolved in its ſeveral menſtrua, colours are produced in proportion as the ſolvent power of thoſe menſtrua is greater or leſs. Thus, iron diſſolved in its ſtrongeſt acid ſolvent, the vitriolic acid, gives green; in its weaker acid ſolvents, the marine and nitrous acids, yellow and orange; and in its weakeſt acid ſolvents, the vegetable acids, red. The colours of the calces of iron precipitated from its ſolution in the vitriolic and nitrous acid, deſcend from green to yellow, and from yellow to red; whereas the changes of colour ariſing from the ſolution of theſe calces, proceed in a contrary order, and aſcend. Mineral ſubſtances are alſo frequently impregnated with iron, and their colours correſpond with the ſtate of the iron contained in them.

In the ſame manner the colours of the ſolution of mercury in the nitrous acid vary, in proportion as the ſolvent is extricated from it, from yellow to orange, and then to red. Thus alſo, thoſe ſubſtances which have the greateſt affinity with the acid of the corroſive ſublimate produced by the ſolution of mercury in the marine acid, diſengage from its ſolution a red precipitate; and thoſe, whoſe affinity with it is leſs, produce a yellow one. But theſe colours are liable to ſome variation, according to the greater or leſs quantity of acid in the ſolution. Mercury diſſolved in the vitriolic and in the vegetable acids, exhibits, in proportion as its ſolvent is taken from it, the ſame colours which, under ſimilar circumſtances, are afforded by that metal diſſolved in the other acids. All theſe mercurial preparations become red, when they are deprived of the principal part of their menſtruum; and mercury calcined by heat, without the addition of any acid, acquires the ſame colour. Its colour, however, is ſubject to variation, from the action of its ſolvents; and thus the phoſphoric acid changes the red to yellow and white. The ſame law obtains in the changes of colour to which the mineral manganeſe is ſubject; for Mr. Delaval found, that by means of the different degrees of power in the ſeveral ſolvents, theſe colours were produced in their regular priſmatic order, viz. yellow, green, blue, purple, and red. The various phenomena of the *ſympathetic* INK of M. Hellot conform to the ſame law, and are urged by Mr. Delaval as arguments to eſtabliſh it. Heat and cold, he obſerves, are not neceſſary agents in the production or ſuppreſſion of the colour. But it appears, that the alterations are effected by the moiſture of the air, attracted by the ſaline matter when cold, and expelled from it when heated. When this ink is expoſed

to a moderate heat, in a white china cup, and when the greater part of the water is evaporated, the faline matter becomes green. This colour arifes from a fuperfluous quantity of the marine acid, which foon flies off, and leaves the remaining part blue, flightly inclining to green. It alfo forms a hard, dry mafs, which, in a few minutes after its removal from the fire, grows moift, and aflumes a light red colour. Thefe alterations may be often renewed, by alternately heating and cooling the colqured matter; which does not again become green, after the fuperfluous marine acid is once evaporated. But a drop of fpirit of falt, added to the red or blue mafs, immediately renders it green. When preparations of cobalt are acted upon merely by heat, the order of the changes of colour effected in them, is fuch as, in other inftances, conftantly arifes from that means of attenuation. Thus, when the yellow folution of this mineral, in the marine acid, is heated, it aflumes a green colour, paffing from a lefs to a more refrangible colour. When this folution is cooled, the yellow is reftored.

Mr. Delaval obferves, that, as the inflammable matter, in the entire *metals*, acts ftrongly on the rays of light, it is neceffary to calcine or to divide them into extremely minute particles, in order to examine feparately the action of the calx, or fixed matter, on the rays of light. In order, therefore, to examine all the *metals* in the like circumftances, by reducing them into the fmalleft particles, and depriving them of their phlogifton as much as poffible, he expofed each of them, united with a proper quantity of the pureft glafs, without any additional ingredient, to the greateft degree of fire which they are capable of bearing, without having all colour whatever deftroyed. In this ftate it appears, from a variety of experiments and facts, that they actually do, without any exception, exhibit colours in the order of their denfities, as follow: gold, red; lead, orange; filver, yellow; copper, green; and iron, blue. He has alfo fhewn, that the other preparations of the *metals*, viz. their folutions, precipitates, cryftals, &c. do for the moft part exhibit the fame colour, in the order of their denfities, though not fo invariably as their glaffes; fome fmall variation of colour happening in the more imperfect *metals*, probably from a change of denfity in their different preparations. Thus, gold acquires a red colour, by a minute divifion of its particles, without any addition. In the procefs of calcining lead in the furnace, the firft of the primary colours which it acquires is yellow; the calx paffing from that colour through orange into red. This variety of colours proceeds from the imperfection of the *metal*; which, probably, during its calcination, receives a fmall portion of phlogifton, as well as air; for the effect of fuch an union muft, probably, be a change of colour from orange to red: as Sir Ifaac Newton has fhewn, that bodies reflect more ftrongly in proportion as they poffefs more phlogifton; and that the lefs refrangible colours require a greater power to reflect them. The preparations of filver are yellow: the two moft imperfect metals, copper and iron, being very eafily acted upon by almoft all menftrua, the colours of their folutions, &c. viz. green and blue, are apt to change into each other's order; the copper in fome folvents becoming blue, and the iron green, and in other folvents *vice verfâ*; which probably depends on the increafe or diminution of their denfities. The preparations, &c. of mercury have been already examined. The fpecific gravity of platina being nearly equal to that of gold, it is found, agreeably to the Newtonian doctrine, confirmed by Mr. Delaval, that the precipitates and cryftals obtained from folutions of this *metal* are red; and that a folution of it in aqua regia to perfect faturation is of a dark red, though when diluted, yellow. Delaval's Experimental Inquiry into the Caufe of the Changes of Colours in opake and coloured Bodies, &c. 1777, paffim. Phil. Tranf. vol. lv. art. 3. p. 10, &c.

METALS, *fluxes of.* See FLUXES.

METALS, *granulation of.* See GRANULATION.

METALS, *medicines from.* All medicines that have LEAD in their compofition, are fcarce to be trufted for internal ufe; for we have numerous inftances of the poifonous nature of this *metal*, in the workers at the white lead or cerufs-houfes, and indeed in all who work on that *metal*; and it were enough to banifh the internal ufe of *faccharum faturni*, and the *tinctura antiphthifica*, to read in the Mifcellanea Curiofa, Decad. 3. Obf. 30. how many men were poifoned at a time by drinking of pricked wine, which had been rendered fweet by litharge.

Metals, however, do not act in the body, unlefs diffolved; whence large quantities of crude mercury being fwallowed, prove harmlefs for want of a proper menftruum to diffolve it in the ftomach; but when crude mercury is diffolved in its proper menftruum, as in the making corrofive fublimate, we fee it becomes one of the ftrongeft poifons. Lead, iron, and copper, being much more eafily diffolved than quickfilver, are feldom taken without fome remarkable effect, which muft always prove the greater, the more of an acid humour, or in cafe of copper, even an alkaline is lodged in the ftomach or inteftines. The internal ufe of the cryftals of filver, though fometimes fucceefully given in dropfical cafes, fhould hardly be trufted, on account of their corrofive acrimony, which has fometimes occafioned bloody ftools, and extreme weaknefs. The common tinctures of copper, and folutions of blue vitriol, can fcarce be taken internally with fafety; as being not only emetic, but in fome degree corrofive and poifonous. Even the *aurum fulminans* cannot be fafely given till thoroughly waflied from its falts; and even then if it meet with an acid folvent in the ftomach, it may do very great mifchief. Iron and tin have not been found fo pernicious in the body, but rather beneficial, efpecially iron, when properly prepared and ufed.

Metallic bodies corroded by acids, generally erode when applied to fores. Some of thefe, fublimate mercury for inftance, and particularly arfenic, have fhaken the whole frame of the body, when applied externally; and mercurial preparations do fometimes enter the blood, and produce a falivation. Med. Eff. Edinb. vol. v. art. 24.

METALS, *falts of.* The falts of the feveral *metals* have been medicines long known in the world, and are of excellent ufe in the cure of many diftafes; but they might be of yet infinitely more fervice to the world, if a happier way of extracting them could be found than the general one now in ufe, of doing it by acids, and fuch ftrong and corrofive menftruums. Befide the mifchiefs thefe menftruums bring as corrofives, which is affuredly much lefs than is vulgarly fuppofed, becaufe they lofe the greater part of this in acting on the *metal*, they produce a great number of bad effects, and render the falts unfit for a great number of ufes, by making them all vitriols, that is, by converting them into falts, which, like the common native vitriols, have a feptic and violently acrimonious quality. The cryftals, or falt of filver, called by the chemifts lunar vitriol, are a plain inftance of this. Borrichius and Kunkel devifed another method to be ufed for obtaining the falts of *metals*. This was the ufe of fire inftead of acids, as the menftruum that fhould prey upon the *metal*, and feeking the falts of all *metals* from the mere action of a reverberatory furnace; but this method, though a very laudable attempt, yet is by no means calculated to be of general ufe, becaufe the quantity of falts thus obtained is very fmall, and that obtained with great pains and expence. Kunkel has given the world an account of the effects of another method of treating *metals*, of which he relates wonders; but he conceals the method. The folemn manner in which he declares the fact, however, feems to imply, that what he relates is truth; and he every where fpeaks from his own perfonal knowlege, and the work of his own hands. The menftruum he ufed was known by himfelf and many others, at Hall in Saxony, under the name of *effentia dulcis*; he facredly affirms, that this was neither acid nor corrofive, even in the flighteft degree; that it left behind it no feces, no faline nor earthy matter on evaporation alone; and that it more approached to the nature of fpirit of wine, than to any other known liquid. He fays, that this liquor diffolved even gold, and that fo perfectly, that it would all rife with the liquor in diftillation. Mercury being diffolved in it, and the folution diftilled in a retort, he fays, that only a fmall quantity of earthy matter remained in the retort, which was white, of a fpongy texture, and fixed in the fire; and that the reft of the body of the quickfilver was converted into a thin colourlefs and pellucid fpirit in the receiver; and that gold, treated in the fame manner, and diftilled with a very gentle heat, was left at the bottom of the retort in form of a refin; and that this refin was foluble in common rectified fpirit of wine, as was alfo the earth of the mercury; and that fome days after the folution of this laft earth, the falt with which this fubftance abounded, would feparate itfelf from the menftruum, and form regular cryftals at the fide of the glafs. This, he fays, is the true falt of mercury, containing all the virtues of that *metal*, and not converted into a vitriol or corrofive fubftance, by means of the menftruum ufed to extract it. When the falt has thus formed as many fhoots as it will yield by this procefs, the remaining liquor is to be evaporated gently, and there will be found a like falt at the bottom of the veffel, of a white colour, an agreeable fmell, and infipid to the taffe: this, he fays, is fo fixed in the fire, that it is no more to be deftroyed or altered by it, like the *metal* from which it is obtained. It readily melts into a mafs in the fire; but if it be not immediately after that taken off from the fire, it will run through whatever veffel it is melted in.

The author attributes to this falt all the wonderful vir-

tues that the *metal* it is made from is known to poſſeſs; and gives inſtances of cures performed by it, which are ſo well atteſted, as ſcarce to leave any doubt of his veracity. He ſays, it works mildly by ſtool, urine, and ſweat. The caſes he gives of cures performed by it, are theſe; two women, who were very bad with the venereal diſeaſe, two men in the laſt ſtages of hectic fevers, ſeveral perſons in bad kinds of the ſmall-pox, and ſome in peripneumonies. The reſin-like ſubſtance into which gold is converted by the ſame operation, he ſays alſo may be tranſformed in the ſame manner into a white and ſubtile ſalt, of a very penetrating taſte; and to this he attributes great virtues in the cure of hæmorrhages and epileptic caſes, and adds, that it is an ingredient of the black compound powder, ſo famed for epileptic caſes, prepared at the public orphan hoſpital at Hall. Kunkel's Diſſert. de Sal. Met.

METAL, *prince's*. Copper, though one of the leſs precious *metals*, has yet been found of ſo great uſe in the common affairs of life, that ſcarce any other has been ſubject to ſo many trials for its improvement, or the rendering it either more beautiful or more fit for certain purpoſes.

One of the firſt diſcoveries in theſe attempts was the making it into braſs, by means of an addition of lapis calaminaris; and though it was not at that time known to be a ſtone which contained any *metal*, yet the braſs was always found to weigh one third more than the copper which had been uſed in the proceſs.

This yellow *metal* gave many people hopes of making copper approach yet nearer to gold, and without knowing that zinc was the ſeparated *metalline* part of lapis calaminaris, the experimenters ſoon found, by happy accident, or repeated chance mixtures, that it would give copper a yet finer and purer yellow; but it was alſo found, that this mixed *metal* was much more brittle than braſs made in the common way. This, however, did not prevent the world from ſtill valuing it for ſuch works as were to be finiſhed by caſting, and did not require the hammer; and we, who firſt had it in perfection, called it *prince's metal*, from prince Rupert, whom ſome ſuppoſed to have been the inventor of it, in 1680. But the greateſt perfection this *metal* was ever brought to, was by two Frenchmen, Mr. La Croix, and Mr. Le Blanc. Their methods of making the compoſition, though both beautiful, were very different. Mr. Le Blanc's was the brighteſt, and of the moſt elegant and lively colour; but Mr. La Croix's was greatly ſuperior to that in ductility and ſoftneſs, ſo that it was very eaſily malleable.

Mr. La Croix invented a ſort of varniſh or lacquer for his *metal*, which added a ſomewhat deeper tinge to it, as it was naturally rather too pale; and had this farther advantage, that while it remained on the *metal*, it preſerved it from ruſt or decay. This is a very material point in regard to a *metal* of which copper is the baſis, ſince that is, of all *metals*, moſt ſubject to be injured by the air, or by the contact of liquids of almoſt any kind. Mr. Le Blanc's *metal* is of a deeper, yet equally lively colour, and remarkably bright; and is of ſuch a temper as to be admirably fitted for working. The whole hiſtory of theſe *metals* is certainly, that they are compoſed of zinc and copper in different proportions the one to the other; but it is not eaſy, without the help of numerous experiments, to determine what is to be the true proportion for either.

The microſcope, however, ſhews a manifeſt difference, which may lead ſomewhat towards it; for the *metal* of La Croix is ſeen to be compoſed merely of a number of irregular ſtrix, while the other is diſcovered to conſiſt of always two regular beds of them, which meet in the center of the piece; hence it is that this is always brittle, and will not well poliſh. The fabric of theſe *metals* was long kept a ſecret; but it was always to be diſcovered by melting it in a crucible in a ſtrong fire, when it always ſent up plain flowers of zinc, and the remaining *metal* appeared no other than copper altered by calamine; that is, common braſs. Mem. Acad. Par. 1732. See GOLD-*coloured metal*.

METALS, *painting on*. See PAINTING.

METALS, *ruſt of*. See RUST.

METALS, *line of*. On Gunter's ſector are ſometimes two lines thus called, and noted with the characters of the ſeven *metals*, ☉, ☾, ☿, ♄, ♀, ♂, and ♃; their uſe is, to give the proportions between the ſeveral *metals*, as to their magnitudes and weights.

METALS, *tincture of*. See TINCTURE.

METAL, *to be laid under*, in *Gunnery*, is when the mouth of a gun lies lower than her breech.

METAL, in *Heraldry*. There are two *metals* uſed in heraldry, by way of colours, viz. gold and ſilver; in blazon called *or*, and *argent*.

In the common painting of arms, theſe *metals* are repreſented by white and yellow, which are the natural colour of thoſe *metals*.

In engraving, gold is expreſſed by dotting the coat, &c. all over; and ſilver, by leaving it quite blank.

It is a general rule in heraldry, never to place *metal* upon *metal*, nor colour on colour; ſo that, if the field be of one of the *metals*, the bearing muſt be of ſome colour, and *vice verſâ*; otherwiſe the arms are falſe: though this rule admits of ſome exceptions.

METALEPSIS, in *Rhetoric*, is a figure in which two or more tropes, and thoſe of a different kind, are contained under one word; ſo that ſeveral gradations, or intervening ſenſes, come between the word that is expreſſed, and the thing deſigned by it. Thus, when Sylla ſays of Julius Cæſar, *In one Cæſar there are many Marius's*. Suet. in Vit. c. 1. This is a *metalepſis*. So when Virgil, deſcribing that part of the African coaſt, where Æneas arrived with his ſhips, ſays, *a dark wood hung over it*. Æn. lib. i. ver. 165; and in the words of Dido, Æn. lib. iv. ver. 664, the ſame figure is uſed.

METALLIC, or METALLINE, an adjective applied to any thing that bears a relation to *metals*.

METALLIC *germination, mines, vegetation*, and *vitriols*. See the reſpective ſubſtantives.

METALLORUM *ovum, water*, and *ſulphur*. See the reſpective articles.

METALLURGY, the art of *metals*, that is, of preparing and working *metals*, from the globe or ore, to the uteníil. See MINERALOGY.

Metallurgy includes what relates to the finding of the metallic globe or ore in the mine; the judging of its kind and richneſs, or the proportion of metal therein; the digging or ſeparating it from the earth, and other matters; and the purifying and diſpoſing it into a complete, pure, malleable metal.

Boerhaave divides *metallurgy* into four parts. The firſt teaches how metals grow in the mines, how they are diſcovered, and how procured out of the ſame; the ſecond, how to ſeparate the metallic from the other matter of the ore; the third, how to reduce the ſeparated matter to its ſimplicity and ductility; the fourth, to work, gild, poliſh, and imitate the finer metals in the coarſer.

Dr. Shaw, however, reſtrains *metallurgy* to thoſe operations required to ſeparate metals from their ores, for the uſes of life. Theſe operations are of two kinds, or ſmaller and large; with regard to which the whole art of *metallurgy* may be divided into two parts, ASSAYING and SMELTING.

Dr. Cramer obſerves, that the art of aſſaying conſiſts in a well-made ſeparation of minerals, eſpecially metals, and in a diviſion of the ſeveral conſtituent parts of them from each other, in order that the quantity and quality of each in particular may be known: it is plain that thoſe operations which belong to the general claſs of ſolution, appertain ſtrictly and primarily to this; and that the others which are performed by the aſſayer, are only ſecondary or auxiliary operations. But there is hardly any chemical operation which is not ſometimes neceſſary to be performed in the art of aſſaying: there are many, on the contrary, which are peculiar to aſſaying alone; therefore we ſhall here give a general view of thoſe which properly belong to it; or of thoſe which, though taken from chemiſtry at large, are nevertheleſs uſed by aſſayers; only firſt obſerving that every primary docimaſtical operation may, on account of its effects, be called ſolution; ſince, in every operation, the menſtrua, among which the air and fire have a right to be claſſed, effect a ſolution, by interpoſing themſelves between the parts of the objects to be changed. See MENSTRUUM and FLUX.

Now a docimaſtical ſolution is either

- Dry
  - Fuſion.
  - Vitrification.
  - Scorification.
  - Cupelling.
  - Reduction. } Theſe may be called almoſt univerſal, becauſe they diſſolve either the whole metals, or, at leaſt, by much the greateſt part of the ſubject in hand.
  - Amalgamation.
  - Sublimation.
  - Cementation.
  - Roaſting.
  - Calcination. } We may call theſe partial, as they all diſſolve but one part of the ſubject in hand.
  - Liquation by fuſion.
- or
- Moiſt
  - Elutriation.
  - Edulcoration.
  - Quartation.
  - Moiſt precipitation. } All theſe are partial, and ſeparate ſome parts from the others.

An account of each of theſe may be found under their proper heads.

Dr. Shaw, after mentioning the manner of extracting metal from the ore, by aſſaying and ſmelting, gives ſeveral axioms and canons of *metallurgy*, among which are the following: that the art of aſſaying is hitherto imperfect, but capable of receiving conſiderable improvement from chemical and mechanical knowledge; that the troubleſome and expenſive method of ſeparating gold from ſilver by quartation, may be advantageouſly ſuperſeded,

or

or ſet aſide, by means of fuſion, or a dexterous management of the fire; that gold and ſilver are ſeldom rendered abſolutely pure, or ſeparated from all other kinds of metallic or mineral matters; and that to purify them in this manner requires the uſe of better methods than thoſe commonly uſed for that purpoſe; though the thing itſelf is ſtill performable by art and a ſuitable proceſs; that ſulphur has different effects upon different metals; which effects being well noted, rules of practice might thence be derived, for the farther improvement of *metallurgy*; that the ignobler metals are ſeparable from each other by the application of proper degrees of heat, ſo as to make the more fuſible melt away from the leſs fuſible, at leaſt with the aſſiſtance of lead; that all metals are reducible by burning or calcination, to terreſtrial powders, which, by being melted with any inflammable matter, aſſume their metallique form; that the great enemies to ductility, or the true metallic nature, are ſulphur, cobalt, and things compounded thereof; but that all unctuous or inflammable bodies are friendly to metals, and promote or reſtore their ductility, when melted therewith; that copper may be made to approach to the colour of gold, and at the ſame time not loſe, but increaſe its ductility, by being amalgamated with, and diſtilled from quickſilver; and that probably many artificial or compound metals are diſcoverable by mixing various metalline and mineral bodies together, ſo as greatly to enrich and improve the art of *metallurgy*; that, in general, ores are no more than a natural looſe mixture of metallic matter with earthy and ſulphureous ones; whence artificial ores may be readily made by calcining a metal with ſulphur, and mixing it with earth, ſo as with heat to form ſolid lumps of ore, reſembling thoſe dug out of the mines; and that numerous experiments remain to be made, and facts of nature or obſervations to be regiſtered, or the relations of bodies to be found, before this uſeful ſubject of *metallurgy* can be brought to perfection.

METAMORPHISTS, a ſect of heretics in the ſixteenth century, whoſe diſtinguiſhing tenet was, that the body of Jeſus Chriſt was, upon his aſcenſion into heaven, changed, and metamorphoſed into God.

METAMORPHOSIS, *Μεταμορφωσις*, formed of *μετα*, *change*, or removal from one place or ſtate to another, and *μορφη*, *form*, or *figure*, *transformation*; the change of a perſon or thing into another form.

The ancients held two kinds of *metamorphoſes*; the one real, the other apparent. The *metamorphoſis* of Jupiter into a bull, and of Minerva into an old woman, were only apparent. That of Lycaon into a wolf, and of Arachne into a ſpider, and the like, they ſay, were of the real kind.

Moſt of the ancient *metamorphoſes* include ſome allegorical meaning, relating either to phyſics or morality. Ovid's *Metamorphoſes* is a collection of hiſtories of ſuch transformations, poetically related. Some authors are of opinion, that a great part of the ancient philoſophy is couched under them; and Dr. Hook has made an attempt to unriddle and lay open the hidden meanings of ſeveral of them.

METAPEDIUM, in *Natural Hiſtory*, a name given by ſome authors to a kind of ſtone, called by others *metatarſum*, and ſuppoſed to imitate a human foot. It is only a *luſus naturæ* in the formation of a common pebble.

METAPHOR, Μεταφορα, *μεταφορα*, *tranſlation*, or *diſplacing*; of *μετα*, *trans*, and *φερω*, *I bear*, or *carry*, in *Rhetoric*, a figure of ſpeech, or a ſpecies of TROPE, whereby a word is transferred from its proper ſignification to another, different from it, by reaſon of ſome ſimilitude between them; or whereby the proper denomination of one thing is applied to another; which other thing is more elegantly explained by this tralatitious or foreign name, than by that which naturally belongs to it. As, when we ſay, the light of the underſtanding; to burn with zeal; to float between hope and deſpair, &c.

The *metaphor* is the moſt common of all the figures of ſpeech; and is that uſually meant, when we ſay a thing is ſpoken figuratively.

The *metaphor* is a ſhort ſimile; or, as Cicero calls it, a ſimilitude reduced to a ſingle word; an image being thereby called from its proper ſubject to give the reſemblance of another. An ALLEGORY is no more than a continued *metaphor*.

Quintilian ſays, that a *metaphor* is a ſhort ſimilitude, and differs from it only in this, that the former is compared to the thing we deſign to expreſs, and the latter is put for it. It is a ſimilitude, when I ſay of a man, he has acted like a lion; and a *metaphor*, when I ſay, he is a lion. But though *metaphors* are uſually taken from a ſimilitude between two things; yet ſometimes they are founded in the ſimilitude which two things bear to each other, in ſome particular reſpect, by means of which, what properly belongs to one of them is transferred to the other: the former of which are called ſimple *metaphors*, and the latter analogous. Hence the rudder of a ſhip may be called its reins; for what the reins are to a horſe, that the rudder is to a ſhip, in guiding and directing it. Again, ſome *metaphors* are reciprocal, in which the ſimilitude holds either way. Thus to ſteer and govern are uſed reciprocally, both of a ſhip and a ſtate; the proper expreſſions being to ſteer a ſhip, and govern a ſtate, and the contrary *metaphorical*. From this account, therefore, of the nature of *metaphors*, it may be defined, the application of a word by way of ſimilitude to ſome other thing than what it properly ſignifies.

Quintilian diſtinguiſhes *metaphors* into four kinds: the firſt, when a word is transferred from one animal to another; as when Livy ſays, that Cato uſed to *bark* at Scipio; or, when our Saviour calls Herod, *fox*. The ſecond, when the word is transferred from one inanimate to another; as *bridle*, for *tower*. The third, when inanimates are applied to animates; as the *flower* of youth. And the laſt, when animates are applied to inanimates; as the river *diſdaining* its bounds. And *metaphors* of this kind, which give life and action to inanimate things, are eſteemed the fineſt and ſtrongeſt.

As the *metaphor* is intended to ſet things before the eyes, it becomes ſo much the more perfect, as it ſhews them the more vividly, by repreſenting them in motion and action. Cicero, ſpeaking of a *metaphor*, calls it, the moſt florid manner of expreſſion, and brighteſt ornament of language, that conſiſts in ſingle words. A *metaphor* ſhould have nothing in it either courſe or ſhocking, or that may raiſe it above the ſimplicity of nature, ſo as to be forced and harſh; nor ſhould it appear a *metaphor* to any, but thoſe who view it very cloſely. A *metaphor* ſhould never be carried too far; for, in that caſe, it degenerates into puerility. *Metaphors* ſhould always be followed in the ſame kind; they become unnatural, when different images are introduced. In all *metaphorical* diction, there ſhould be a kind of ſuitableneſs to each other: different ideas are always abſurd; as in this inſtance, the church was beſieged with a deluge of troubles, where the two images, *ſiege* and *deluge*, have no relation.

There is nothing young writers are more faulty in, than the indiſcreet uſe of *metaphors*: thoſe who affect the marvellous, are eternally on the *metaphorical* ſtrain; nor know any bounds or reſtraint. They, who underſtand them beſt, uſe them with the greateſt reſerve. Mr. Addiſon propoſes it as a rule for writers, to imagine their *metaphors* actually painted before them, and to view and examine the juſtneſs of their application and aſſemblage under thoſe circumſtances; throwing every thing out of the writing, but what might be retained in the picture. Card. Perron preſcribes this general rule for *metaphors*, that they muſt always deſcend from the genus to the ſpecies; and never go backwards from the ſpecies to the genus: thus, we ſay figuratively, the *bonds of ſociety*, and not the *human cords* which tie us together; *bond* being a genus, and *cord* a ſpecies.

METAPHRAST, Μεταφραστης, a tranſlator, or perſon who renders an author in another form, or another language, word for word.

A *metaphraſe*, *μεταφρασις*, uſually ſignifies ſomething more than either a paraphraſe, or a tranſlation: according to Baillet, a *metaphraſt* implies a tranſlator, gloſſator, and interpolator, all at once.

METAPHYSICS, Μεταφυσικα, *tranſnaturalis*; a branch of ſcience, about whoſe nature and idea there is ſome difference among authors.

The word is formed from the prepoſition *μετα*, *trans*, *beyond* or *above*; and *φυσις*, *nature*, or *φυσικος*, *natural*.

Some define *metaphyſics*, that part of ſcience which conſiders ſpirits and immaterial beings; which others chooſe to diſtinguiſh by the name of PNEUMATICS.

Others, keeping cloſer to the etymology of the word, explain *metaphyſics* by *trans-natural*, or *præter-natural*, or even *poſt-natural philoſophy*: becauſe it is ſubſequent in contemplation to the phyſical, though prior to it in the real order of beings.

Others, with more propriety, conceive *metaphyſics* to be what ſome others call ONTOLOGY, or *ontoſophy*, i. e. the doctrine *de ente*, or of being, *quatenus* being.

In the ſame view, ſome philoſophers call this ſcience by the name *philoſophia*, or *ſcientia generalis*, as being the foundation, or, as it were, the ſtamen or root from whence all the other parts of philoſophy ariſe, and wherein they all meet; its object being *being* in the abſtract, or general, not reſtrained to this or that ſpecies of beings; not to ſpirit any more than body: ſo that the doctrines of *metaphyſics* are applicable to all beings whatever.

Philoſophers, again, are divided as to the notion of a ſcience *de ente* in general. Some hold it real, preciſe, and ſolid enough to be demonſtrated; but others judge it too

obſcure, faint, and confuſed, to be admitted into philoſophy.

Being, abſtracted from every ſort or ſpecies of being, is certainly a very vague term, and does not ſeem to give ſcope enough for a ſcience: we do not ſee how it can affect the mind as an object. Add, that the common *metaphyſics* cannot demonſtrate any part of its ſubject, but aſſume the whole: there are no principles or axioms, wherein to demonſtrate *metaphyſics*, which contain the principles of all other ſciences.

The firſt, who wrote profeſſedly on the ſubject of *metaphyſics*, is Ariſtotle. Indeed, he is the firſt who uſes the word: Μεταφυσικα, is the title of one of his books; but this ſome of his commentators will have to ſignify no more than *after the books of phyſics*. M. du Hamel, taking the prepoſition μετα in the ſenſe of *poſt*, is even of opinion, that the word was coined by Ariſtotle's followers; and that it was unknown to Ariſtotle himſelf.

Ariſtotle's *metaphyſics* ſeem to have been intended for a kind of natural theology. The *metaphyſics* of Ariſtotle have been lately illuſtrated by the ingenious Mr. Harris, in his treatiſe intitled, Philoſophical Arrangements, 8vo. 1775. F. Malebranche and Mr. Locke have written much more clearly, and conſiſtently of *metaphyſics*, than any of the ancients.

METAPHYSICAL, ſomething belonging to METAPHYSICS.

The word is alſo uſed to denote ſomething ſubtile, abſtract, and refined. In which ſenſe we ſay, Such a reaſoning, ſuch a proof, is too *metaphyſical*, &c.

A *metaphyſical* caſe is an imaginary or chimerical caſe, which can ſcarce ever happen, or not without much difficulty; and which ought not be laid down as a rule for common occaſions.

METAPHYSICAL *certitude, diſtinction, evidence, form, perfection, univerſality.* See the reſpective ſubſtantives.

METAPHYSICAL *ſect*, in the *Hiſtory of Learning*, is one of the two great ſects into which the philoſophical world was divided about the beginning of the ſeventeenth century. This ſect followed the ſyſtem of Des Cartes, and conſidered truth as attainable by abſtract reaſoning; and from a ſmall number of abſtract truths, deduced a long ſeries of propoſitions in order to arrive at a preciſe and accurate knowledge of God and nature, of body and ſpirit. The *metaphyſical* philoſophers, ſuppoſing that many things are known by man with the utmoſt certainty, diſcovered an undue propenſity to form their opinions and doctrines into a regular ſyſtem. The other ſect was the MATHEMATICAL. See CARTESIANS.

METAPLASM, METAPLASMUS, compounded of μετα, and πλασσω, *fingo*, in *Grammar*, a tranſmutation, or change, made in a word, by adding, retrenching, or altering, a letter or ſyllable thereof.

METAPTOSIS, a word uſed by many phyſical writers to expreſs a change of one diſtemper into another, whether it be by *diadoche* or *diadoxis*, as it is called; when the change is for the better, and the morbid matter removes from a more noble to an ignoble part: or by *metaſtaſis*, when the change is for the worſe, and the morbid matter removes from an ignoble to a more noble part.

METASTASIS, Μεταστασις, in *Medicine*, the removal of a morbid humour from one part to another; frequently obſerved in nervous caſes.

A *metaſtaſis*, or tranſlation, is ſometimes alſo found in the groſſer humours; the refluent blood taking up digeſted matter from one part, and diſpoſing it upon another.

METASTASIS, Μεταστασις, *remotio*, in *Rhetoric*, is uſed for the removing the blame from the perſon accuſed to another perſon, or laying it upon ſomething as a cauſe. Thus Adam's excuſing himſelf by blaming Eve, is an example of the former; and the laying the crime of drunkenneſs upon the wine, is an inſtance of the latter.

METATARSIUS, a fleſhy maſs lying under the ſole of the foot, fixed by one end in the fore-part of the great tuberoſity of the os calcis, and that, running forward from thence, terminates in a kind of ſhort tendon, which is fixed in the tuberoſity, and poſterior part of the lower ſide of the fifth bone of the *metatarſus*. It may move this bone, much after the ſame manner as the metacarpius moves the fourth bone of the metacarpus. Winſlow.

METATARSUM, in *Natural Hiſtory*, a name given by authors to a ſort of ſtone, ſuppoſed to repreſent a human foot. See METAPEDIUM.

METATARSUS, from μετα, *beyond*, and ταρσος, *the inſtep*, in *Anatomy*, that part of the human ſkeleton, containing the middle of the foot. See *Tab. Anat. (Oſteol.) fig.* 3. *n.* 30. *fig.* 7. *lit. e.*

The *metatarſus* conſiſts of five bones, reaching from the heel to the toes; whereof that, which ſuſtains the great toe, is the thickeſt; and that, which ſuſtains the next toe, the longeſt: the reſt grow each ſhorter than the other. They are longer than the bones of the metacarpus; in other things they are like them, and are articulated to the toes, as theſe are to the fingers.

METATHESIS, Μεταθεσις, formed of μετα, *trans*, and θεσις, *poſition*, *tranſpoſition*, a grammatical figure, whereby letters or ſyllables of a word are tranſpoſed, or ſhifted out of their natural ſituation; as *Evander* for *Evander*; *I præ* for *præ*.

METATHESIS, a word uſed by medical writers for a change of place in ſuch humours, or other diſeaſed parts, as cannot be abſolutely removed or ſent off. Thus a *metatheſis* of a cataract is a depreſſion thereof, ſo that it no longer ſhuts out the light.

METATOR, among the Romans, a quarter-maſter. Out of every legion a tribune, and ſome centurions, were appointed to go before the army, in order to chooſe a place for a camp, and aſſign and mark out quarters to each legion.

METAXA, a word uſed by ſome medical writers to expreſs ſilk.

METEGAVEL, in our *Old Writers*, a tribute or rent paid in victuals; which was a thing uſual in this kingdom, as well with the king's tenants as others, till the reign of king Henry the Firſt.

The word is Saxon, *metegavel*, i. e. *cibi gabulum, ſeu vectigal.*

METEL, in *Natural Hiſtory*, the name of a ſort of *nux vomica*, of the ſame ſhape with the common kind, but ſomewhat larger.

METEMPSYCHI, in *Church Hiſtory*, heretics, who, in imitation of the Pythagoreans, maintained the tranſmigration of ſouls. See METEMPSYCHOSIS.

METEMPSYCHOSIS, Μετεμψυχωσις, formed of μετα, *beyond*, and ψυχωσις, *animation*, or *enlivening*, in the *Ancient Philoſophy*, the paſſage or tranſmigration of the ſoul of a man, after death, into the body of ſome other animal.

Pythagoras and his followers held, that, after death, men's ſouls paſſed into other bodies, of this or that kind, according to the manner of life they had led. If they had been vicious, they were impriſoned in the bodies of miſerable beaſts, there to do penance for ſeveral ages; at the expiration whereof, they returned afreſh to animate men. But, if they had lived virtuouſly, ſome happier brute, or even a human creature, was to be their lot.

What led Pythagoras into this opinion was, the perſuaſion he had, that the ſoul was not of a periſhable nature: whence he concluded, that it muſt remove into ſome other body, upon its abandoning this. Lucan treats this doctrine as a kind of officious lye, contrived to mitigate the apprehenſion of death, by perſuading men, that they only changed their lodging; and only ceaſed to live, to begin a new life.

Reuchlin denies this doctrine; and maintains, that the *metempſychoſis* of Pythagoras implied nothing more than a ſimilitude of manners, deſires, and ſtudies, formerly exiſting in ſome perſon deceaſed, and now revived in another alive. Thus, when it was ſaid, that Euphorbus was revived in Pythagoras, no more was meant than that the martial virtue, which had ſhone in Euphorbus at the time of the Trojan war, was now, in ſome meaſure, revived in Pythagoras, by reaſon of the great reſpect he bore the athletæ. For thoſe people wondering how a philoſopher ſhould be ſo much taken with men of the ſword, he palliated the matter, by ſaying, that the ſoul of Euphorbus, i. e. his genius, diſpoſition, and inclinations, were revived in him. And this gave occaſion to the report, that Euphorbus's ſoul, who periſhed in the Trojan war, had tranſmigrated into Pythagoras.

Ficinus aſſerts, that what Plato ſpeaks of the migration of a human ſoul into a brute, is intended allegorically, and is to be underſtood only of the manners, affections, and habits, degenerated into a beaſtly nature by vice. Serranus, though he allows ſome force to this interpretation, yet inclines rather to underſtand the *metempſychoſis* of a reſurrection.

Pythagoras is ſaid to have borrowed the notion of a *metempſychoſis* from the Egyptians; others ſay, from the ancient Brachmans. It is ſtill retained among the BANIANS, and other idolaters, of India and China; and makes the principal foundation of their religion. So extremely are they bigotted to it, that they not only forbear eating any thing that has life, but many of them even refuſe to defend themſelves from wild beaſts. They burn no wood, leſt ſome little animalcule ſhould be in it; and are ſo very charitable, that they will redeem, from the hands of ſtrangers, any animals that they find ready to be killed. See PYTHAGOREANS.

METEMPTOSIS, from μετα, *poſt*, and πιπτω, *to fall*, a term in *Chronology*, expreſſing the ſolar equation, neceſſary to prevent the new moon from happening a day too late.

By which it ſtands contradiſtinguiſhed from *præmptoſis*, which ſignifies the lunar equation, neceſſary to prevent the new moon from happening a day too ſoon.

The

The new moons running a little backwards, that is, coming a day too soon at the end of three hundred and twelve years and a half; by the *proemptosis*, a day is added every three hundred years, and in three every two thousand four hundred years; on the other hand, by the *metemptosis*, a biſſextile is ſuppreſſed each one hundred thirty-four years: that is, three times in four hundred years. Theſe alterations are never made but at the end of each century; that period being very remarkable, and rendering the practice of the calendar eaſy.

There are three rules for making this addition, or ſuppreſſion, of the biſſextile-day, and, by conſequence, for changing the index of the epacts. 1. When there is a *metemptosis* without a *proemptosis*, the next following, or lower index, muſt be taken. 2. When there is a *proemptosis* without a *metemptosis*, the next preceding or ſuperior index is to be taken. 3. When there are both a *metemptosis* and a *proemptosis*, or when there is neither the one nor the other, the ſame index is preſerved. Thus, in 1600, we had D; in 1700, by reaſon of the *metemptosis*, C was taken; in 1800, there will be both a *proemptosis* and a *metemptosis*; ſo the ſame index will be retained. In 1900, there will be a *metemptosis* again, when B will be taken, which will be preſerved in 2000, becauſe there will then be neither the one nor the other. This is as far as we need compute for it: but Clavius has calculated a cycle of 301800 years; at the end of which period, the ſame indices return in the ſame order. See EPACT.

METEOR, in *Phyſiology*, a changeable, moveable, imperfect mixt body, or reſemblance of a body, appearing in the atmoſphere, formed out of the matter that floats there, and exhibiting various appearances.

The Greeks call them, μετεωρα, q. d. *ſublimia*, or *highraiſed*, from μετα, and αειρω, *pro* αιωρω, from αειρω *tollo*; the Latins, *impreſſiones*, as making ſigns or impreſſions in the air.

Meteors are of three kinds:

METEORS, *igneous* or *fiery*; ſuch are lightning, thunder, the Aurora borealis, ignis fatuus, draco volans, falling ſtars, and other fiery phenomena, appearing in the air.

METEORS, *aerial*, or *airy*, conſiſt of flatulent and ſpirituous EXHALATIONS; ſuch are winds, whirlwinds, and hurricanes.

METEORS, *aqueous*, or *watery*, are compoſed of vapours, or watery particles variouſly ſeparated, and condenſed by heat and cold; ſuch are clouds, rainbows, hail, ſnow, rain, dew, and the like. See each in its proper place.

The formation of *meteors* is explained pretty largely by Deſcartes, in a treatiſe expreſs. Ariſtotle and Gaſſendus have alſo handled the ſame ſubject. Dr. Woodward's opinion is, that the matter of many *meteors* is, in great meaſure, of a mineral nature; that the mineral particles, contained in the ſtrata of the earth, are raiſed by the ſubterraneous heat, together with the vapours aſcending from the abyſs, and pervading thoſe ſtrata; eſpecially at ſuch times as the ſun's heat is ſufficient to penetrate the exterior parts of the earth, and to make room for their eſcape into the atmoſphere. Theſe ſulphureous, nitrous, and other active and volatile mineral particles, form various *meteors*, according to the various circumſtances attending their combination. The nature, cauſes, &c. of each are explained under its diſtinct article.

METEOROLOGICAL *journal*, is a table recording the daily ſtate of the air, exhibited by the barometer, thermometer, hygrometer, anemometer, and other *meteorological* inſtruments. We have many journals of this kind, kept at the houſe of the Royal Society, and by different obſervers in other places, in the Philoſophical Tranſactions, the Memoirs of the Academy of Sciences, and ſimilar publications.

METEOROLOGY, the doctrine of meteors; explaining their origin, formation, kinds, phenomena, &c.

METEOROMANCY, a ſpecies of divination by meteors, principally by lightning and thunder: this method of divination paſſed from the Tuſcans to the Romans, with whom, as Seneca informs us, it was held in high eſteem.

METEOROS, μετεωρος, from μετα, and αειρω, *to elevate*, in *Medicine*, elevated, ſuſpended, ſublime, erect, tumid. Thus μετεωρα πλευμαθα, are expounded by Galen, Com. ad Aph. 7. lib. vi. ſublime pains: thoſe which are above the peritonæum, or affect the ſuperficial and external parts of the body. Theſe pains are oppoſed to ſuch as are deeply ſeated, and called τα μη μετεωρα, not ſublime, but deep, and ſeated within the peritonæum.

METEOROSCOPE, from μετεωρος, *high*, and σκοπεω, of σκοπομαι, *I view, obſerve*, a name which the ancient mathematicians gave to ſuch inſtruments as they uſed for obſerving and determining the diſtances, magnitudes, and places of the heavenly bodies; many of which they regarded as meteors.

The name, however, may much more properly be applied to METEOROLOGICAL inſtruments.

METESSIL, an officer of the eaſtern nations, who has the care and overſight of all the public weights and meaſures, and fees that things are made juſtly according to them.

METHEGLIN, a drink prepared of honey; one of the moſt pleaſant and general drinks in the northern parts of Europe afford; and much uſed among the ancient inhabitants.

The word is Welſh, *meddyglin*, where it ſignifies the ſame. There are divers ways of making it; one of the beſt whereof follows: put as much new honey, naturally running from the comb, into ſpring-water, as that, when the honey is throughly diſſolved, an egg will not ſink to the bottom, but be juſt ſuſpended in it; boil this liquor for an hour, or more, till ſuch time as the egg ſwim above the liquor about the breadth of a groat; when very cool, next morning, it may be barrelled up, adding to each fifteen gallons an ounce of ginger, as much of mace and cloves, and half as much cinnamon, all groſly pounded; a ſpoonful of yeaſt may be alſo added at the bung-hole, to promote the fermentation. When it has done working, it may be cloſely ſtopped up; and, after it has ſtood a month, it ſhould be drawn off into bottles.

The duty on *metheglin*, ſold by retail or otherwiſe, is 11*d.* a gallon. See MEAD.

METHOD, METHODUS, from μεθοδος, in *Logic* and *Rhetoric*, the art or rule of diſpoſing things in ſuch a manner, as that they may be eaſily comprehended; either in order to diſcover the truth, which we ourſelves are ignorant of; or to ſhew and demonſtrate it to others when known, or to fix it in the memory. See DISPOSITION.

Gaſſendus diſtributes *method*, with regard to its object, into three kinds, or branches, viz. inventionis, *the method of invention*, or diſcovering a truth unknown.

Methodus judicii, the method of judging or determining of a truth, or propoſition, propoſed.

And *methodus demonſtrationis*, or method of demonſtration; that is, of exhibiting it to another.

Method is diſtributed by others into two general kinds, viz. *natural* and *arbitrary*. *Natural method* is that which obſerves the order of nature, and proceeds in ſuch a manner, as that the knowledge of things which follow depends in a great meaſure on the things which go before. *Arbitrary method* leaves the order of nature, and accommodates itſelf to many purpoſes: as to treaſure up things, and retain them in the MEMORY; to harangue and perſuade mankind to any practice in the religious or civil life; or to delight, amuſe, or entertain the mind. This kind of *method* is chiefly purſued in poetry and oratory.

Natural method is again ſubdivided into two kinds; the one of *reſolution*, which is that we generally uſe in our enquiry after truth. The other of *compoſition*, by which the truth, once found, is taught or imparted to others.

In the *method of reſolution*, called alſo by geometers the *analytic method*, we proceed from ſome general known truths to others, which belong to ſome particular or ſingular thing.

In the *method of compoſition*, called alſo the *ſynthetic method*, we propoſe ſome certain general truths, from which we produce particular truths.

If, in the *method* of reſolution, we lay down any axioms, it is not immediately in the beginning, and all together, but as they are found neceſſary in the diſquiſition: on the contrary, in the *method* of compoſition, they are propoſed all together in the beginning, before there is any abſolute need of them.

The two *methods* differ from each other, as the *methods* of ſearching out a genealogy, either by deſcending from the anceſtors to their poſterity, or by aſcending from the poſterity to the anceſtors: both of them have this in common, that their progreſſion is from a thing known to another unknown. Thoſe things, that are known in each, are ſet in the front, or firſt place, that by them we may be able to arrive at thoſe which are not known.

Dr. Watts, in his excellent Treatiſe on Logic, has compriſed the general requiſites of true *method* in the purſuit or communication of knowledge, under the following heads. It muſt be 1. Safe or ſecure from error: in order to which great care ſhould be uſed in laying the foundations of a diſcourſe, or the ſcheme of our thoughts, on any ſubject; the primary and fundamental propoſitions ſhould not only be evident and true, but made familiar to the mind by dwelling on them before we proceed farther; our ground ſhould be made firm in every ſtep; and we ſhould draw up all our propoſitions and arguments with ſo much caution, and expreſs our ideas with ſuch a juſt limitation, as may preclude or anticipate any objections. 2. Plain and eaſy: for which purpoſe, we ſhould begin always with thoſe things that are beſt known and moſt obvious, and proceed by regular and eaſy ſteps to

things that are more difficult; nor should we affect excessive haste in learning or teaching any science, nor hurry at once into the midst of it; nor again crowd too many thoughts and reasonings into one sentence or paragraph, beyond the apprehension or capacity of our readers or hearers; we should also avoid too many subdivisions; and acquire in early life, a clear and easy way of expressing our conceptions. 3. Distinct: in order to which no needless heterogeneous matter should be introduced; every complicated theme or idea should be divided into its distinct single parts, as far as the nature of the subject, and our present design require; we should call every idea, proposition, and argument, to its proper class, and keep each part of the subject in its own place; and in the partition of our discourse into distinct heads, take heed that particulars do not interfere with the general, nor with each other. 4. Full, or without defect: and this is necessary in explaining a subject; in enumerating its parts or properties; in asserting or proving any truth; in illustrating or arguing a point of difficulty; in drawing up a narrative; and in solving any difficulty. 5. Short, or without superfluity: for this purpose, all needless repetitions, tedious prolixity, long parenthesis, useless explications, proofs, and refutations, and all scholastic forms, should be carefully avoided. 6. Proper to the subject, the design, and the age and place in which we dwell. 7. Connected: in order to this, we should keep our main design always in view, and preserve an apparent tendency in all the parts of our discourse towards it; the mutual relation and dependence of the several branches of our discourse should be so just and evident, that every part may lead onward to the next; and we should acquaint ourselves with all the proper and decent forms of transition from one part of a discourse to another, and practise them as occasion offers.

The *synthetic method* is only practicable in things, whose principles we perfectly know; as in geometry, which is wholly employed in the consideration of abstract modes, of which our mind has clear and adequate ideas. When the inquiry is into substances, as in physics, we cannot make use of the *method of composition*, because their kinds and intimate essences are unknown to us.

This *method* has not been by any so justly and accurately observed, as by the mathematicians, whose principles are perfectly known; its laws, therefore, will be best drawn from their practice: for which, see COMPOSITION.

The supreme law of the philosophical *method* is, to premise that which is necessary towards the understanding or establishing what follows.

The mathematical and philosophical *methods* are the same, as may be seen by the practice of the geometers of antiquity, who constantly observe the law here mentioned.

Several authors, as Ramus, Messrs. de Port-Royal, &c. have accused Euclid of want of *method*. Had these gentlemen attended to the supreme law of all true *method*, they would have been more cautious in their censures.

METHOD, *methodus*, is more particularly used, in *Mathematics*, for divers particular processes for solving problems. In this sense we say

METHOD *of exhaustions*. See EXHAUSTIONS.

METHOD *of fluxions*. See FLUXIONS.

METHOD *de maximis & minimis*, &c. See MAXIMUM.

METHOD *of tangents*. See TANGENTS.

METHOD, *differential*, &c. See DIFFERENTIAL.

METHOD, *exponential*, &c. See EXPONENTIAL.

METHOD, *peristic*. See PORISTIC.

METHODISTS, in *Botany*, persons who have attempted that study upon certain principles, and have bestowed their labours upon the disposition and arrangement of plants, and allotting them proper and distinctive names. See BOTANY.

METHODISTS, in *Ecclesiastical History*, is a denomination applied to different sects, both papists and protestants. The popish *Methodists* were those polemical doctors, of whom the most eminent arose in France towards the middle of the seventeenth century, in opposition to the Huguenots or protestants. The *Methodists*, from their different manner of treating the controversy with their opponents, may be divided into two classes. The one may comprehend those doctors, whose method of disputing with the protestants was disingenuous and unreasonable, and who followed the examples of those military chiefs, who shut up their troops in intrenchments and strong holds, in order to cover them from the attacks of the enemy. Of this number were the Jesuit Veron, who required the protestants to prove the tenets of their church by plain passages of scripture, without being allowed the liberty of illustrating those passages, reasoning upon them, or drawing any conclusions from them; Nihusius, an apostate from the protestant religion; the two Walenburgs, and others, who confined themselves to the business of answering objections and repelling attacks; and cardinal Richelieu, who confined the whole controversy to the single article of the divine institution and authority of the church. The *Methodists* of the second class were of opinion, that the most expedient manner of reducing the protestants to silence, was not to attack them by piecemeal, but to overwhelm them at once, by the weight of some general principle or presumption, some universal argument, which comprehended, or might be applied to all the points contested between the two churches: thus imitating the conduct of those military leaders, who, instead of spending their time and strength in sieges and skirmishes, endeavoured to put an end to the war by a general and decisive action. These polemics rested the defence of popery upon prescription; the wicked lives of protestant princes who had left the church of Rome; the crime of religious schism; the variety of opinions among protestants, with regard to doctrine and discipline; and the uniformity of the tenets and worship of the church of Rome. To this class belong Nicolle, the Jansenist doctor, the famous Bossuet, &c. Moth. Eccl. Hist. vol. iv p. 307, &c. 8vo.

The protestant *Methodists* form a very considerable class, principally of the lower people in this country. They sprung up about fifty years ago, at Oxford, and were soon divided into two parties, the one under the direction of Mr. George Whitefield, and the other under that of the two brothers, John and Charles Wesley. These leaders, and, if we except Mr. William Law, founders of *Methodism*, were educated at Oxford, and received episcopal ordination; and always professed themselves advocates for the articles and liturgy of the established church: though they more commonly practised the dissenting mode of worship. But conceiving a design of forming separate communities, superior in sanctity and perfection to all other Christian churches, and impelled to a very considerable degree by a zeal of an enthusiastic and extravagant kind, they became itinerant preachers, and, being excluded from most of our churches, exercised their ministry in private houses, fields, &c. not only in Great Britain and Ireland, but also in America: thus collecting a very considerable number of hearers and proselytes, both amongst the members of the established church and the dissenters. The theological system of Mr. Whitefield and his followers is Calvinistic: that of Mr. Wesley and his disciples Arminian; and the latter maintains the possibility of attaining sinless perfection in the present state. The subordinate teachers of both these classes of *Methodists* are generally men of no liberal education, and they pretend to derive their ministerial abilities from special communications of the spirit. The *Methodists* of both parties, like other enthusiasts, make true religion to consist principally in certain affections and inward feelings, which it is impossible to explain, but which, when analysed, seem to be mechanical in their spring and operation, and they generally maintain, that Christians will be most likely to succeed in the pursuit of truth, not by the dictates of reason, or by the aids of learning, but by laying their minds open to the direction and influence of divine illumination: and their conduct has been directed by impulse.

METHODISTS, METHODICI, in the *History of Medicine*, a sect of ancient physicians, who reduced the whole art of healing to a few common principles or appearances.

The *Methodists* were the followers of Thessalus; whence they were also called *Thessalici*. They were strenuously opposed by Galen in several of his writings; who scrupled not to assert, that the *methodical sect* ruined every thing that was good in the art.

Quincy mistakenly uses *Methodists*, *Methodici*, for those physicians, who adhere to the doctrine of Galen, and the schools; and who cure with bleedings, purges, &c. duly applied according to the symptoms, circumstances, &c. in opposition to empirics and chemists, who use violent medicines, and pretended secrets or nostrums.

METHONICA, in *Botany*. See *Superb* LILY.

METOCHE, *Μετοχη*, in the *Ancient Architecture*, a term used by Vitruvius, to signify the space or interval between the dentils. See *Tab. Archit. fig.* 28. See DENTICLES.

Baldus observes, that, in an ancient MS. copy of that author, the word *metatome* is found for *metoche*. Hence Daviler takes occasion to suspect, that the common text of Vitruvius is corrupted: and concludes, that it should not be *metoche*, but *metatome*, q. d. section.

METONIC *cycle*, in *Chronology*. See CYCLE, and *Golden* NUMBER.

METONYMY, *Μετωνυμια*, from *μετα*, *trans*, and *ονομα*, *nomen*, *name*; a rhetorical trope, consisting in a transmutation or change of names; or a putting of the effect for the cause, or the subject for the adjunct; and *vice versâ*. The *metonymy* is the most considerable of all the tropes, next

next to a METAPHOR, whether we conſider its force and elegancy, or the frequent uſe of it both in ſpeaking and writing. It is ſometimes alſo called *tranſnominatio*, and differs not much from the HYPALLAGE.

There are four kinds of *metonymies* in principal uſe: the firſt, when we put the inventor for the thing invented; as Bacchus for wine, Ceres for bread. The ſecond, when the effect is put for the cauſe, whether the agent, or only the means and inſtrument: thus Virgil, Æn. vi. v. 844. calls the two Scipios, the deſtruction of Libya, becauſe they were the agents who effected it; and Horace, Carm. i. 1. 2. compliments Mæcenas with the titles of being his guard and honour, that is, his guardian and the author of his honour: and the author is put for his works. The third, when the ſubject is put for the adjunct. By ſubject here in a large ſenſe of the word, may be underſtood that, wherein ſome other thing is contained, or about which it is converſant; as likewiſe the poſſeſſor with reſpect to the thing he poſſeſſes, and the thing ſignified when put for the ſign of it: thus, in the firſt of theſe ways, the ſeat of any faculty or affection is put for the faculty or affection itſelf; as in the phraſes, a man of a clear head or of a warm heart: the place, where any actions are performed, is put for the actions done in it; the country or place of reſidence for the inhabitants; the time for the perſons living in it: in the ſecond way, the object is uſed for the perſon, or thing employed about it: as when Cicero, pro Mil. cap. 4. ſays, in time of battle, the laws, i. e. the judges, are ſilent. By the third way, we ſay to deſtroy or ruin a man, meaning not his perſon but his eſtate. In the laſt way, ſtatues and pictures are called by the names of the perſons which they repreſent.

The fourth kind of *metonymy* is that in which the adjunct is put for the ſubject, which is done in the ſame variety of ways as the former.

Voſſius adds two other ſpecies of *metonymy*, viz. of the antecedent and the conſequent, which bear ſome analogy to the cauſe and effect, as the one does at leaſt give occaſion to the other. By the former, to hear, when ſpoken of a ſuperior, ſometimes ſignifies to grant or comply with: by the latter, it is not unuſual to ſay, I ſubſcribe, or ſet my hand to ſuch a thing, meaning that we aſſent or agree to it, &c.

METOPE, or METOPA, in *Architecture*, the ſquare ſpace or interval between the triglyphs, in the Doric frieze. See *Tab. Archit. fig.* 25. N° 9.

The word, in the original Greek, ſignifies the diſtance between one aperture, or hole, and another, or between one triglyph and another; the triglyphs being ſuppoſed to be ſolives or joiſts that fill the apertures. It is derived from μετὰ, *inter*, *between*, and ὀπὴ, *foramen*.

The ancients uſed to adorn theſe parts with carved works, or paintings, repreſenting the heads of oxen, veſſels, baſons, and other utenſils of the heathen ſacrifices.

As there is found ſome difficulty in diſpoſing the triglyphs and *metopes* in that juſt ſymmetry which the Doric order requires; ſome architects make it a rule, never to uſe this order but in temples.

METOPE, *ſemi*, is a ſpace ſomewhat leſs than half a *metope*, in the corner of a Doric frieze.

Le Clerc obſerves, that the beauty of *metopes* conſiſts in their regularity, on appearing to be perfect ſquares; and yet when they are equally ſquare, they appear to be leſs in height than in breadth, on account of the projecture of the little bandelet; for which reaſon they ſhould be made a minute or two more in height than in breadth, in order to make their appearance uniform.

He alſo obſerves, that when the triglyphs and *metopes* follow each other regularly, the columns muſt only ſtand one by one; excepting thoſe of the inner angles, which ought always to be accompanied by two others, one on each ſide; and here it is worth remarking, that theſe two columns which accompany that of the angle, are not leſs neceſſary on account of the ſolidity of the building, than of the regularity of the intercolumniations.

METOPIUM, in *Botany*, a name given by Pliny to the plant which produces the gum ammoniacum. He ſays that the ancient Greeks called it alſo by this name, but in that he errs. See AMMONIAC.

METOPOSCOPY, Μετωποσκοπία, from μέτωπον, *frons*, *forehead*, and σκοπία, *inſpection*, of σκοπέω, *I view*, the art of diſcovering the temperament, inclinations, and manners of perſons, by inſpecting their features, and the lines in their faces, and eſpecially of their foreheads.

Metopoſcopy, is no more than a branch of phyſiognomy; the latter taking its conjectures from all parts of the body: but both the body and the branch are extremely precarious, not to ſay vain.

Ciro Spontoni, who has written on the ſubject of *metopoſcopy*, obſerves, that there are ſeven principal lines to be conſidered in the forehead; each of which has its peculiar planet. The firſt is the line of Saturn, the ſecond of Jupiter, &c.

METRE, or METER, *Metre*, in *Poetry*, denotes a ſyſtem of feet of a juſt length. Ariſtides defines *metre*, a ſyſtem of feet compoſed of diſſimilar ſyllables, of a juſt extent. In which ſenſe *metre* amounts to much the ſame with genus carminis, or the ſort of verſe, and differs from rhythm.

METRENCHYTES, a name given by chirurgical writers to a ſort of ſyringe, contrived on purpoſe for injecting medicinal ſubſtances into the womb.

METRETES, the name of a meaſure uſed among the ancients, containing ſomewhat more than nine gallons.

METRICAL *verſes* are thoſe conſiſting of a determinate number of long and ſhort ſyllables; as thoſe of the Greek and Latin poets.

Capellus obſerves, that the genius of the Hebrew language is incompatible with *metrical* poetry.

METRICE, or METRICA, among the *Ancients*, was that part of poetry employed about the quantities of ſyllables, feet, ſorts of metre, or verſe, &c.

METROCOMIA, from μήτηρ, *mother*, and κώμη, *town*, or *village*, a term in the *Ancient Church Hiſtory*, ſignifying a borough, or village, that had other villages under its juriſdiction.

What a metropolis was among cities, a *metrocomia* was among country towns. The ancient *metrocomiæ* had each its chorepiſcopus or rural dean, and here was his ſee or reſidence. See METROPOLIS and CHOREPISCOPUS.

METRONOMI, Μέτρονομοι, among the Athenians, officers that inſpected all ſorts of meaſures, except thoſe of corn; there were five of them in the city, and double that number in the Pyræus, in which the greateſt mart in Attica was kept.

METROPOLIS, Μητρόπολις, from μήτηρ, *mother*, and πόλις, *city*; the *mother-city*, &c. the capital of a country, or province: or the principal city, and, as it were, mother of all the reſt.

METROPOLIS is alſo applied to archiepiſcopal churches, and ſometimes to the principal or mother-church of a city.

The Roman empire having been divided into thirteen dioceſes, and one hundred and twenty provinces, each dioceſe, and each province, had its metropolis, or capital city, where the proconſul, or the vicar of the empire, had his reſidence.

To this civil diviſion the eccleſiaſtical was afterwards adapted, and the biſhop of the capital city had the direction of affairs, and the pre-eminence over all the biſhops of the province. His reſidence in the *metropolis* gave him the title of *metropolitan*.

This erection of *metropolitans* is referred to the end of the third century, and was confirmed by the council of Nice. Indeed archbiſhop Uſher, and De Marca, maintain it to be an eſtabliſhment of the apoſtles; but in vain: for it is next to certain, that the eccleſiaſtical government was regulated on the plan of the civil; and that it was hence the name and authority of *metropolitans* were given to the biſhops of the capital cities of the empire, or the provinces that compoſed it. This is ſo true, that, in the conteſt between the biſhop of Arles and the biſhop of Vienne, each of whom laid claim to the *metropolitanſhip* of the province of Vienne, the council of Turin appointed, that whichever of them could prove his city to be the civil metropolis, ſhould enjoy the title and rights of eccleſiaſtical *metropolitan*.

Nothing is more evident than the perfect equality that reigned among the primitive churches; nor does there even appear, in the firſt century, the ſmalleſt trace of that aſſociation of provincial churches, from which, ſays Moſheim, councils and *metropolitans* derive their origin. The order and decency of thoſe aſſemblies which were called councils, and introduced towards the cloſe of the ſecond century, required, ſays this author, that ſome one of the provincial biſhops met in council, ſhould be inveſted with a ſuperior degree of power and authority; and hence, he adds, the rights of *metropolitans* were derived. See PATRIARCHS.

Though the eccleſiaſtical government, however, was modelled on the political, yet, in Gaul, and ſome other countries, the diſtinctions of *metropolitan* and primate were not obſerved till very late. As the præfectus Galliæ reſided by turns at Trevoux, Vienne, Arles, and Lyons, he communicated the rank and dignity of *metropolitan* and primate to each of them in their turn; and yet none of the Gallican biſhops aſſumed to themſelves the rights, nor even the precedence, of *metropolitans*. The epiſcopate levelled them all, and they had no regard but to the privileges of ſeniority. This equality laſted till the fifth century, when the conteſt between the biſhops of Vienne and Arles was ſet on foot.

M. Du

M. Du Pin obſerves, that, in the provinces of Africa, excepting thoſe whereof Carthage was the *metropolis*, the place where the moſt aged biſhop reſided became the *metropolis*: the reaſon of which, without doubt, was this, that neither the proconſul, nor præfectus, ever fixed their reſidence any where.

The ſame author obſerves, alſo, that, in Aſia, there were *metropoliſes* merely nominal; that is, which had no ſuffragan, nor any rights of *metropolitans*. The biſhops of Nice, Chalcedon, and Berytus, had the precedence of the other biſhops, and the title of *metropolitans*, but this without any other prerogative beſides the honour of the appellation; they themſelves being ſubject to their *metropolitans*.

A *metropolitan* has the privilege of ordaining his ſuffragans; and appeals from ſentences paſſed by the ſuffragans are preferred to the *metropolitan*. See ARCHBISHOP.

METROPTOSIS, a word uſed by ſome medical authors to expreſs a falling down of the womb, or prolapſus uteri. There is a plaſter calculated to be of ſervice againſt this caſe, and called, hence, *emplaſtrum metroptoticum*.

METTESHEP, or METTENSCHEP, in our old writers, an acknowledgment paid in a certain meaſure of corn; or a fine or penalty impoſed on tenants, for defaults in not doing their cuſtomary ſervices of cutting the lord's corn.

METUPORANGA, in *Ornithology*, the name of a Braſilian bird, called by ſome *tapetotil*, and by Aldrovand by the too general name *gallus Indicus*.

It much approaches to the gallinaceous fowls, called *mitu* and *pauxi*, of the ſame country, but differs from them in having no tail, if the deſcriptions of authors are accurate, and from the *mitu* in having a protuberance of the ſize of a cherry over the top of its beak. Margrave.

METYS, a word uſed by many of the ancient writers to expreſs a ſubſtance collected by bees, in order to the ſtopping up cracks and crevices in their hives.

The old authors mention three kinds of ſubſtances uſed by the bees on this occaſion, the *metys*, *piſſiceros*, and *propolis*. The moderns uſe only the latter term to expreſs every thing of this kind. The *metys* and *piſſoceros* ſeeming to have been only the ſame PROPOLIS, more or leſs mixed with wax. This ſubſtance is a reſin, of a middle conſiſtence between the hard and the fluid ones. It is uſually of a reddiſh brown on the ſurface, and yellow within, and is collected from ſeveral trees, of which the poplar ſeems to be the principal, and the willow the next.

MEU, in *Botany*. See SPIGNEL.

MEVELEVITES, in *Modern Hiſtory*, a ſort of derviſes, or religious, among the Turks, ſo called from Mevelevia, their founder. They affect to be very patient, humble, modeſt, and charitable; but in reality are very debauched and diſhoneſt.

MEVIUM, a name mentioned by Fallopius and others, as given by ſome medical writers to the venereal diſeaſe.

MEUM, in *Botany*. See SPIGNEL.

MEUTANG, in *Botany*, the name of a flower much eſteemed by the Chineſe, which, on that account, they call the king of flowers. It is larger than our roſe, and imitates its figure, only its leaves are more expanded. As its ſmell comes ſhort of that of the roſe, ſo in beauty the roſe is outdone by it. It has no prickles, and its colour is a mixture of white with purple, but ſo as to incline moſt to white; yet ſometimes there are found reddiſh and yellow ones. The tree it grows on is not unlike our alder-tree, and is cultivated throughout that large empire with great care, being covered in the ſummer time with a ſhade to defend it from the ſcorching heat of the ſun.

MEWING, a diſorder incident to all kinds of birds; being the caſting of their feathers.

MEZAIR, in the *Manege*. See MEZAIR.

MEZANINE, or MEZZANINE, a term uſed by ſome architects to ſignify an Attic, or little ſtory contrived occaſionally over the firſt ſtory, for the conveniency of a wardrobe, or the like.

The word is borrowed from the Italians, who call *mezzanini* thoſe little windows, leſs in height than breadth, which ſerve to illuminate an Attic, or entreſole.

MEZEREAN, in *Botany*. See SPURGE *Laurel*.

MEZUZOTH, in the *Jewiſh Cuſtoms*, certain pieces of parchment, which the Jews fix to the door-poſts of their houſes, taking that literally which Moſes commands them, ſaying, "Thou ſhalt never forget the laws of thy "God, but thou ſhalt write them upon the poſts of thy "houſe, and on thy gates." This expreſſion means nothing elſe, but that thou ſhalt always remember them, whether thou comeſt into thy houſe, or goeſt out. But the Hebrew doctors imagined, that the law-giver meant ſomething more than this. They pretended that, to avoid making themſelves ridiculous, by writing the commandments of God without their doors, or rather to avoid expoſing themſelves to the profanation of the wicked, they ought, at leaſt, to write them on a parchment, and to incloſe it in ſomething. Therefore they wrote theſe words upon a ſquare piece of parchment, prepared on purpoſe with a particular ink, and a ſquare kind of character. Deut. vi. 4, 5, 6, 7, 8, 9. "Hear O Iſrael, "the Lord our God is one Lord, &c." Then they left a little ſpace, and afterwards went on, Deut. xi. 13. "And it ſhall come to paſs, if thou ſhalt hearken dili-"gently to my commandments, &c." as far as. "Thou "ſhalt write them upon the door-poſts of thy houſe, &c." After this they rolled up the parchment, and put it into a caſe of reeds, or other matter; they wrote on the end of the caſe the word *Shadai*, which is one of the names of God; and they put it at the doors of their houſes, chambers, and all places moſt frequented; they fixed it to the knockers of the door, on the right ſide; and as often as they entered in, or went out, they touched it in this place, with the end of their finger, which they afterwards kiſſed out of devotion. The Hebrew word *mezuza* properly ſignifies the door-poſts of a houſe; but it is alſo given to this roll of parchment now mentioned. Leo of Modena may be here conſulted.

MEZZA *pauſa*, in the *Italian Muſic*, *half a pauſe*, intimates that the part wherein it is found muſt lie ſtill the time of a ſemibreve in common time. See PAUSE.

MEZZA *tinta*. See TINTA.

MEZZO *ſoprano*, in the *Italian Muſic*, is the high tenor, which has the cleff C on the ſecond line.

MEZZO-TINTO, in *Sculpture*, a particular manner of engraving figures on copper.

Mezzo-tinto is ſaid to have been firſt invented by prince Rupert, about the year 1649; and Mr. Evelyn, in his Hiſtory of Chalcography, gives us a head, performed by that prince, in this way; though Mr. Le Blond is ſaid to have introduced it into practice, with the greateſt ſucceſs.

The prince laid his grounds on the plate with a channelled roller; but one Sherwin, about the ſame time, laid his grounds with a half-round file, which was preſſed down with a heavy piece of lead. Both theſe grounding tools have been laid aſide, for many years; and a hand-tool, reſembling a ſhoemaker's cutting-board-knife, with a fine erenelling on the edge, was introduced by one Edlin, a ſmith by trade, who afterwards became a *mezzo-tinto* painter.

It is very different from the common way of engraving. To perform it, they rake, hatch, or punch the ſurface of the plate all over with a knife, or inſtrument made for the purpoſe, firſt one way, then the other, acroſs, &c. till the face of the plate be thus entirely furrowed with lines or furrows, cloſe and as it were contiguous to each other; ſo that, if an impreſſion was then taken from it, it would be one uniform blot, or ſmut.

This done, the deſign is drawn, or marked, on the ſame face; after which, they proceed with burniſhers, ſcrapers, &c. to expunge and take out the dents, or furrows, in all the parts where the lights of the piece are to be; and that more or leſs, as the lights are to be ſtronger or fainter; leaving thoſe parts black, which are to repreſent the ſhadows, or deepenings of the draught.

As it is much eaſier to ſcrape or burniſh away parts of a dark ground correſponding with the outline of any deſign ſketched upon it, than to form ſhades upon a light ground, by an infinite number of hatches, ſtrokes, and points, which muſt all terminate with exactneſs on the outline, as well as differ in their force and manner, the method of ſcraping, as it is called, in *mezzo-tinto*, conſequently becomes much more eaſy and expeditious, than any other method of ENGRAVING. The inſtruments uſed in this kind of engraving are CRADLES, SCRAPERS, and BURNISHERS.

In this engraving, the plate muſt be prepared and poliſhed in the ſame manner as for other ENGRAVING (ſee alſo COPPER-*plates*); and afterwards divided equally by lines, parallel to each other, and traced out with very ſoft chalk. The diſtance of theſe lines ſhould be about one third of the length of the face of the CRADLE, which is to be uſed, and theſe lines ſhould be marked with capital letters, or ſtrokes of the chalk. The cradle is then to be placed exactly betwixt the two firſt lines, and paſſed forwards in the ſame direction; being kept as ſteady as poſſible and preſſed upon with a moderate force. The ſame operation muſt be repeated with reſpect to all the other lines; till the inſtrument has thus paſſed over the whole ſurface of the plate. Other lines muſt be drawn then from the extremities of the other two ſides, in the ſame manner; which, interſecting the firſt

at right angles, will with them form ſquares; and the ſame operation muſt be repeated, with the cradle, as in the caſe of the firſt. New lines muſt then be drawn diagonally, and the cradle paſſed betwixt them as before; and when the firſt diagonal operation is performed, the lines muſt be croſſed at right angles as the former, and the cradles paſſed betwixt them in the ſame manner. The plate having undergone the action of the cradle, according to the diſpoſition of the firſt order of lines, a ſecond ſet muſt be formed, having the ſame diſtances from each other as the firſt. But they muſt be ſo placed as to divide thoſe already made into ſpaces one third leſs than their whole extent; i. e. every one after the firſt on each ſide will take in one third of that before it, e. g. beginning at A, of which the firſt third muſt be left out; a third of B will conſequently be taken in; and ſo of the reſt. Theſe lines of the ſecond order muſt be marked with ſmall letters, or leſſer ſtrokes, to diſtinguiſh them from the firſt: and the ſame treatment of the plate muſt be purſued, with reſpect to them, as was practiſed for the others. When this ſecond operation is finiſhed, a third order of lines muſt be made; the firſt of which, e. g. in A, muſt omit two thirds of it, and conſequently take in two thirds of B, &c. By theſe means the original ſpaces will be exactly divided into equal thirds; and the cradle muſt be again employed betwixt theſe lines as before. When the whole of this operation is finiſhed, it is called *one turn*; but, in order to produce a very dark and uniform ground, the plate muſt undergo the repetition of all theſe ſeveral operations, for above twenty times; beginning to paſs the cradle again betwixt the firſt lines, and proceeding in the ſame manner through all the reſt. When the plate is prepared with a proper ground, the ſketch muſt be called on it, by rubbing the paper on the backſide with chalk. It is alſo proper to overtrace it afterwards with black-lead or Indian ink. The ſcraping is then performed, by paring or cutting away the grain of the ground in various degrees; ſo that none of it is left in the original ſtate, except in the touches of the ſtrongeſt ſhade. The general manner of proceeding is the ſame as drawing with white upon black paper. The maſſes of light are firſt begun with; and thoſe parts, which go off into light in their upper part, but are brown below, the reflections are then entered upon; after which the plate is blackened with a printer's blacking-ball made of felt, in order to diſcover the effect; and then the work is proceeded with; obſerving always to begin every part in the places where the ſtrongeſt lights are to be.

The art of ſcraping *mezzo-tinto* has been applied to the printing with a variety of colours, in order to produce the reſemblance of paintings. The inventor of the method of doing this was J. C. Le Blon, a native of Frankfort, and pupil of Carlo Maratta, between the years 1720 and 1730. It was eſtabliſhed by the inventor on this principle, that there are three primitive colours, of which all the reſt may be compoſed, by mixing them in various proportions: that any two of theſe colours being mixed together, preſerve their original power, and only produce a third colour, ſuch as their compound muſt neceſſarily give; but if tranſparent colours be mixed, and three primitive kinds compounded together, they deſtroy each other, and produce black, or a tendency to it, in proportion to the equality or inequality of the mixture; and that, if, therefore, theſe three colours be laid, either ſeparately, or upon each other, by three plates, engraved correſpondently, on theſe principles, to the colouring of the deſign, the whole variety of tints neceſſary may be produced. The requiſites, therefore, to the execution of any deſign in this method of printing, are as follow. 1. To ſettle a plan of the colouring to be imitated; ſhewing where the preſence of each of the three ſimple colours is neceſſary, either in its pure ſtate, or combined with ſome other, to produce the effect required; and to reduce this plan to a painted ſketch of each, in which not only the proper outlines, but the degree of ſtrength ſhould be expreſſed. 2. To engrave three plates according to this plan, which may print each of the colours exactly, in the places where, and proportion in which they are wanted. 3. To find three tranſparent ſubſtances, proper for printing with theſe three primitive colours. The manner in which Mr. Le Blon prepared the plates was as follows: the three plates of copper were firſt well fitted with reſpect to ſize and figure to each other, and grounded in the ſame manner as thoſe deſigned for *mezzo-tinto* prints: and the exact place and boundary of each of the three primitive colours, conformably to the deſign, were ſketched out on three papers, anſwering in dimenſions to the plate. Theſe ſketches were then called on the plates; and all the parts of each plate, that were not to convey the colour, to which it was appropriated, to the print, were entirely ſcraped away, as in forming the light of *mezzo-tinto* prints. The parts that were to convey the colour were then worked upon; and where the moſt light or diluted teints of the colour were to be, the grain in the ground was proportionably taken off; but where the full colour was required, it was left entire. In this regard was had, not only to the effects of the colour in its ſimple ſtate, but to its combined operation, either in producing orange-colour, green, or purple, by its admixture with one alone; and likewiſe to its forming brown, grey, and ſhades of different degree, by its co-operation with both the others. But though the greateſt part of the engraving was performed in the *mezzo-tinto* manner, yet the graver was employed occaſionally for ſtrengthening the ſhades; and for correcting the outline, where it required great accuracy and ſteadineſs. It was found neceſſary ſometimes to have two ſeparate plates for printing the ſame colour, in order to produce a ſtronger effect: but the ſecond plate, which was uſed to print upon the firſt, was intended only to glaze and ſoften the colours in particular parts that might require it. With reſpect to the black and brown teints, which could not be ſo conveniently produced, in a due degree, by the mixture of the colours, umber and black were likewiſe uſed.

With reſpect to the order in which the plates are to be applied, it may be proper to obſerve, that the colour which is leaſt apparent in the picture ſhould be laid on firſt; that which is betwixt the moſt and leaſt apparent, next; and that which predominates, laſt; except where there may be occaſion for two plates, for the ſame colour, as was before mentioned; or where there is any required for adding browns and ſhades.

Mr. Le Blon applied this art to portraits, and ſhewed, by the ſpecimens he produced, the poſſibility of its being brought, by farther improvements, to afford imitations of painting, which might have ſome value. It is nevertheleſs much better adapted to the ſimpler ſubjects, where there are fewer intermixtures of colours; and where the accuracy of the reflections, and demi-teints, are not ſo eſſentially neceſſary to the truth of the deſign, from the greater latitude of form, and diſpoſition of the colour, as in plants, anatomical figures, and ſome ſubjects of architecture. But perhaps plates engraved, or rather finiſhed, with the tool, particularly with reſpect to the outline, would be better accommodated in ſome of theſe caſes, than thoſe prepared only by ſcraping.

Mr. Cochin remarks, at the end of an account he has given of Mr. Le Blon's manner, that though this ingenious artiſt confined his method principally to the uſe of three colours; yet ſhould this invention be again taken up and cultivated, there would be more probability of ſucceſs in uſing a greater variety: and that ſeveral different kinds might be printed by one plate; provided they were laid on in their reſpectively proper places, by printing balls, which ſhould be uſed for that colour only. His hint might however be very greatly improved, by the further aſſiſtance of pencils, accommodated to the plates, for laying on the colours in the proper parts.—Handmaid to the Arts, vol. ii. p. 182, &c. Encyclopedie, Art. GRAVURE *en Couleurs*, &c.

For the method of taking off *mezzo-tinto* prints on glaſs, ſee BACK-*painting*.

MIASMA, *miaſmata*, is uſed to ſignify ſuch particles, or atoms, as are ſuppoſed to ariſe from diſtempered, putrefying, or poiſonous bodies; and to affect people at a diſtance.

MICA, in *Natural Hiſtory*, a name given by authors who have written of foſſils to many of the bractearia, or ſmall ſmall-ſpangled TALCS, whether in pure maſſes of themſelves, or immerſed in the matter of other foſſils. It conſiſts of thin, flexible, ſhining plates; which by expoſure to fire become brittle and crumble, and by violent heat are vitrifiable. *Mica* is either colourleſs and tranſparent, or it is coloured, red, brown, green, or black, and ſemi-tranſparent.

The principal kinds of theſe are the white and the yellow, from their colour and ſplendid appearance, called the ſilver and gold glimmer, or *mica aurea* and *mica argentea*.

Theſe have frequently led people of ſanguine imaginations, who have met with them in different places, to ſuppoſe they had found ores of gold and ſilver, but they in reality contain not the leaſt grain of either of thoſe metals, and are mere talc in ſmall flakes, accidentally coloured. The yellow kind is found in many parts of the world, but no where ſo plentifully as in Arabia and Ægypt. In Germany and France there is alſo conſiderable plenty of it, and in our American plantations it is found in great abundance; nor is England without it even in various forms.

We have some of it in pure homogeneous masses; some mixed among stony matter, and some among sand. The white is very plentiful in Silesia and Bohemia, and also in France, Italy, and England. It is like the former; found either pure, or mixed among the matter of stone, and makes a very glittering and beautiful appearance. The coloured *micæ* generally contain some metallic matters, chiefly iron, and are much more fusible than these which are pure and colourless: and Mr. Justi pretends that he has discovered a new metallic substance in yellow *micæ*, which was of a blackish grey colour, but when mixed with gold heightened the lustre, without destroying the malleability of that metal, though itself is brittle.

The *micæ* have a soft touch resembling that of unctuous substances; they are not soluble by acids; they are incapable of yielding sparks, when struck by steel, as flints do; or of forming a tenacious paste, with water, as clay does; or of hardening, when calcined and mixed with water, as gypsum does. *Micæ* is, therefore, neither a calcareous, siliceous, argillaceous, nor gypseous earth. The colourless transparent *micæ* called Muscovite glass, is used as panes for windows. Dr. Hooke has described the beautiful colours that appear in thin plates of Muscovy glass, in his Micrographia, p. 48.

In Jemptland, a crumpled kind of *micæ* is manufactured into kettles and other vessels, and also for hearths. The powder of this stone is mixed with sea-salt, and from the mixture a marine acid is obtained by distillation.

MICAH, in *Scripture History*, one of the minor prophets, who was contemporary with Isaiah, and whose prophecy, foretelling the captivity of the ten tribes, and the advancement and establishment of the Christian church, very much resembles his.

MICARAGUÆ *pomum*, a name given by some authors to the Spanish pear.

MICHAELMAS, the feast of St. Michael the archangel; held on the 29th of September.

MICHAEL's *wing*. See WING.

MICHAH, a word used by some of the chemical writers to express copper.

MICHALALATLI, in *Ornithology*, a name by which Nieremberg informs us some of the Mexicans call the ACHALALACTLI.

MICHELIA, in *Botany*, the name of a genus of plants, of the *polyandria polyginia* class, the characters of which are these: that the calyx is composed of three leaves; that the flowers have fifteen petals; and that the fruit are berries containing four seeds.

MICROCOSM, μικροκοσμος, formed from μικρος, *little*, and κοσμος, *world*, a Greek term, literally signifying *little world*; chiefly understood of *man*, who is so called by way of eminence, as being an epitome of all that is wonderful, in the great world or microcosm.

MICROCOSMETER, a name given by Dolœus to an imaginary being, which he supposes to reside in the brain, and direct all the actions.

MICROCOUSTICS, the same with MICROPHONES.

MICROGRAPHIA, MICROGRAPHY, compounded of μικρος, *small*, and γραφη, *description*, a description of the parts and proportions of objects that are too small to be viewed without the assistance of a microscope.

MICROMETER, an astronomical machine, which, by means of a very fine screw, serves to measure extremely small distances in the heavens; as the apparent diameters of the planets, to a great degree of accuracy.

The word comes from the Greek, μικρος, *parvus*, and μετρον, *mensura*: in regard a small length, e. g. an inch is hereby divided into vast numbers of parts, e. g. in some, 2800, and in others, more.

This instrument is so contrived as to move a fine wire parallel to itself, in the plane of the picture of an object, formed in the focus of a telescope, and with great exactness to measure its perpendicular distance from a fixed wire in the same plane; and thus are measured small angles, subtended by remote objects at the naked eye. E. g. Let a planet be viewed through the telescope; and when the parallel wires are opened to such a distance as to appear exactly to touch two opposite points in the circumference of the planet, it is evident, that the perpendicular distance between the wires is then equal to the diameter of the picture of the planet, formed in the focus of the object-glass. Let this distance, whose measure is given by the mechanism of the *micrometer* hereafter described, be represented by the line $p\,q$, *Tab. III. Optics, fig.* 44. then since the measure of the focal distance $q\,L$ may be also known, the ratio of $q\,L$ to $p\,q$, that is, of the radius to the tangent of the angle $q\,L\,p$, will give the angle itself by a table of lines and tangents; and this angle is equal to the opposite angle P L Q, which the real diameter of the planet subtends at L, or at the naked eye. There is some controversy about the invention of the *micrometer*. Mess. Auzout and Picard have the credit of it in common fame, as being the first who published it, in the year 1666; but Mr. Townley, in the Philosophical Transactions, reclaims it for one of our own countrymen, Mr. Gascoigne. He relates, that, from some scattered papers and letters of this gentleman, he had learnt, that, before our civil wars, he had invented a *micrometer*, of as much effect as that since made by M. Auzout, and had made use of it for some years, not only in taking the diameters of the planets, and distances upon land, but in determining other matters of nice importance in the heavens; as the moon's distance, &c.

Mr. Gascoigne's instrument fell into the hands of Mr. Townley, who says, that by the help of it, he could make above forty thousand divisions in a foot. This instrument being shewn to Dr. Hooke, he gave a drawing and description of it, and proposed several improvements in it, which may be seen in the Philosophical Transactions Abr. vol. i. p. 227. Mr. Gascoigne divided the image of an object, in the focus of the object-glass, by the approach of two pieces of metal, ground to a very fine edge, in the place of which, Dr. Hooke would substitute two fine hairs, stretched parallel to one another. Two other methods of Dr. Hooke, different from this, are described in his Posthumous Works, p. 497, &c. An account of several curious observations which Mr. Gascoigne made by the help of his *micrometer*, particularly in the mensuration of the diameter of the moon and other planets, may be seen in the Phil. Trans. vol. xlviii. p. 190. where Dr. Bevis refers to an original letter of Mr. Gascoigne, to Mr. Oughtred, written in 1640-1. for an account given by the author of his own invention, &c.

Mons. de la Hire, in a discourse on the æra of the inventions of the *micrometer*, pendulum clock, and telescope, read before the Royal Academy of Sciences in 1717, makes M. Huygens the inventor of the *micrometer*. That author, he observes, in his Observations on Saturn's Ring, &c. published in 1659, gives a method of finding the diameters of the planets by means of a telescope; viz. by putting an object, which he calls *virgula*, of a proper bigness to take in the distance to be measured, in the focus of the convex object-glass: in this case, says he, the smallest object will be seen very distinctly, in that place of the glass. By such means, he adds, he measured the diameters of the planets, as he there delivers them.

This *micrometer*, M. De la Hire observes, is so very little different from that published by the marquis De Malvasia, in his Ephemerides, three years after, that they ought to be esteemed the same: and the *micrometer* of the marquis differed yet less from that published four years after by Auzout and Picard. Hence, M. De la Hire concludes, that it is to M. Huygens the world is indebted for the invention of the *micrometer*; without taking any notice of the claim of our countryman Mr. Gascoigne, which, however, is prior by many years to any of them.

M. De la Hire says, that there is no method more simple or commodious for observing the digits of an eclipse, than a net in the focus of the telescope. These, he says, were generally made of silken threads, and for this particular purpose six concentric circles had also been made use of, drawn upon oiled paper; but he advises to draw the circles on very thin pieces of glass, with the point of a diamond. He also gives several particular directions to assist persons in using them. In another memoir he shews a method of making use of the same net for all eclipses, by using a telescope with two object-glasses, and placing them at different distances from one another. Ac. Par. 1701, and 1717.

MICROMETER, *construction and use of the*. Wolfius describes a *micrometer* of a very easy and simple structure, first contrived by Kirchius, thus:

In the focus of a telescope fit a brass or iron ring A B (*Tab. Astron. fig.* 11.) with female screws diametrically opposite to each other; into these insert male screws C E and F B, of such length, as that they may be turned in the tube, so as to touch each other: and with this instrument very small spaces in the heavens may be accurately measured.

For when any objects, viewed through a tube, appear contiguous to the screws, if these be turned till they just touch two opposite points, whose distance is to be measured, it will be evident how many threads of the screw they are apart. To determine how many seconds answer to each thread, applying the tube towards the heavens, turn the screws, till they touch two points, whose distance is already accurately known; and observe the number of threads corresponding to that interval; thus, by the rule of three, a table may be made of the seconds corresponding to the several threads; by means whereof, without greater labour, the distances of any points may be determined.

The

The ſtructure of another *micrometer*, with the manner of fitting it to the teleſcope, and applying it, is as follows: A B C *(Tab. Aſtron. fig. 12.)* is a rectangular braſs frame, the ſide A B being about three inches long, and the ſide B C, as likewiſe the oppoſite ſide A *g*, about ſix inches; and each of the three ſides about eight tenths of an inch deep: the two oppoſite ſides of this frame are ſcrewed to the circular plate, to be mentioned hereafter.

The ſcrew P, which has exactly forty threads in an inch, being turned round, moves the plate G D E F, along two grooves made near the tops of the two oppoſite ſides of the frame; and the ſcrew Q, having the ſame number of threads in an inch as P, moves the plate R N M Y along two grooves, made near the bottom of the ſaid frame, in the ſame direction as the former plate moves, but with only half the velocity of that other: theſe ſcrews are turned both at once, and ſo the plates are moved along the ſame way, by means of a handle turning the endleſs ſcrew S, whoſe threads fall in between the teeth of the pinions on the ſcrews P and Q. And note, that two half revolutions of the endleſs ſcrew S carry the ſcrew P exactly once round.

The ſcrew P turns the hand *a*, faſtened thereto, over a hundred equal diviſions, made round the limb of a circular plate, to which the above named two oppoſite ſides of the frame are ſcrewed at right angles: the teeth of the pinion on the ſcrew P, whoſe number is 5, take into the teeth of a wheel on the backſide of the circular plate, whoſe number is 25. Again, on the axis of this wheel is a pinion of two, which takes into the teeth of another wheel, moving about the centre of the circular plate, on the outſide thereof, and having fifty teeth; this laſt wheel moves the leſſer hand *b* once round the above mentioned circular plate, in the $\frac{1}{25}$th part of the time the hand *a* is moving round: for becauſe the number of teeth in the pinion of the ſcrew P are 5, and the number of teeth of the wheel this pinion moves, are 20; therefore the ſcrew P moves four times round in the time that wheel is moving once round. Farther, ſince there is a pinion of two which takes into the teeth of a wheel, whoſe number is 50; therefore this wheel with 50 teeth will move once round in the time that the wheel of 20 teeth moves 25 times round; and, conſequently, the ſcrew P, or hand *a*, muſt move a hundred times round in the ſame time as the wheel of 50 teeth, or the hand *b*, has moved once round.

Hence it follows, that if the circular plate W, which is faſtened at right angles to the other circular plate, be divided into two hundred equal parts, the index *x*, to which the handle is faſtened, will move five of thoſe parts in the ſame time in which the hand *a* moves one of the hundred diviſions round the limb of the other circular plate. Thus, by means of an index *x*, and plate W, every fifth part of each of the diviſions round the other plate may be known.

Farther, ſince each of the ſcrews P and Q have exactly forty threads in an inch; therefore the upper plate G D E F will move one inch while the hand *a* moves forty times round: the four thouſandth part of an inch while the hand moves over one of the diviſions round the limb; and the twenty thouſandth part of an inch while the index *x* moves one part of the two hundred round the limb of the circular plate W: and the under plate R N M Y will move half an inch, the two thouſandth part of an inch, and the ten thouſandth part of an inch, the ſame way, in the ſaid reſpective times.

Hence, if the under plate, having a large round hole therein, be fixed to a teleſcope, ſo that the frame is moveable, together with the whole inſtrument, except the ſaid lower plate; and the ſtrait ſmooth edge H I, of the fixed plate A B I H; as likewiſe the ſtrait ſmooth edge D E, of the moveable plate G D E F, be perceivable through the round hole in the under plate, in the focus of the object-glaſs; then, when the handle of the *micrometer* is turned, the edge H I, of the narrow plate A B I H, fixed to the frame, and D E, of the moveable plate, will appear through the teleſcope equally to approach to, or recede from, each other.

By theſe edges we ſhall be able to meaſure the apparent diameters of the ſun, moon, &c. the manner of doing which take as follows:

Suppoſe, in looking at the moon through the teleſcope, you have turned the handle till the two edges D E and H I are opened, ſo as juſt to touch or claſp the moon's edges; and that there were twenty-one revolutions of the hand *a*, to complete that opening: firſt ſay, as the focal length of the object-glaſs, which ſuppoſe ten feet, is to radius, ſo is one inch to the tangent of an angle ſubtended by one inch in the focus of the object-glaſs; which will be found twenty-eight minutes thirty ſeconds: again, becauſe there are exactly forty threads of the ſcrews in one inch; ſay, if forty revolutions of the hand *a* give an angle of 28′ 30″, what angle will twenty-one revolutions give? The anſwer will be, fifteen minutes eight ſeconds; and ſuch was the moon's apparent diameter. And ſo may the apparent diameters of any other objects be taken. It muſt be here obſerved, that the diviſions on the top of the plate G D E F are diagonal diviſions of the revolutions of the ſcrews, with diagonal diviſions of inches againſt them: thus, as the ſaid plate ſlides along, theſe diagonals are cut by diviſions made on the edge of the narrow plate K L, fixed to the oppoſite ſides of the frame by means of two ſcrews. Theſe diagonal diviſions ſerve for a regiſter to count the revolutions of the ſcrews, and to ſhew how many there are in an inch, or the parts of an inch.

Dr. Derham tells us, that his *micrometer* is not, as uſually, to be put into a tube, but to meaſure the ſpectres of the ſun on paper (of any radius), or to meaſure any part of them. By this means he can eaſily, and very exactly, with the help of a fine thread, take the declination of a ſolar ſpot at any time of the day; and, by his half-ſeconds watch, meaſure the diſtance of the ſpot from the ſun's eaſtern and weſtern limb.

A *micrometer* of the beſt ſort is made in this manner: in the middle of an oblong plate of braſs, A B, *Tab. III. Optics, fig. 45*, there is cut an oblong hole, *a b c d e f*, (to be placed in the focus of a teleſcope,) having a fine wire *b e* extended lengthways over the middle of it, at right angles to two ſlender braſs bars or ſights *g h*, *i k* lying croſs the hole; of which *g h* is fixt to the plate A B by ſcrews at *g* and *h*, but *i k* is moved parallel to *g h* by twiſting a round knob C fixt upon one end of a long iron ſcrew D E, which turns upon a tapering point at its end D, while its other end turns round in a hole at E in the centre of an index-plate E F, fixt at right angles to the main plate A B. The long ſcrew D E works through two hollow ſcrews in two cubical blocks of braſs fixt behind the plate *l m*, bent ſquare to the plate *n s*, that ſlides upon the main plate A B, either backward or forward, and carries a perpendicular arm *o p* extended over the hole *b e*; while *p* the extremity of the arm *o p* ſlides under a braſs ledge *q r*, ſcrewed to the main plate A B, along the ſide of the hole. One ſide *i t*, of the moveable ſight-plate *i k t*, lies over the arm *o p*, being fixt to it by the flat-headed ſcrews at *t* and *t*, the holes in the plate *i t* being oblong or larger than the ſhanks of the ſcrews, to give liberty for placing the edge *i k* coincident with *g h*, when carried up to it by turning the ſcrew D E by the knob C; the part *i k*, which projects over the arm *o p*, being hammered down to lie flat upon the main plate A B. The edge *i k*, after this adjuſtment, will always move parallel to the edge *g h*; its inclination to the ſcrew D E being every where the ſame, provided the ſcrew be ſtraight, and the interval of the concave ſcrews behind *l m* be ſufficiently great and their motion ſteady. For this purpoſe about a quarter-round of a third concave ſcrew preſſes upon the long ſcrew D E at *v*, the block of it being fixt to the middle of a ſpringing plate *w x y*, whoſe extremities lying behind the blocks at *l*, *m*, not ſo near as to touch them, are preſſed towards them with ſcrews at *w* and *x*; which occaſions the block at *v* to ſpring upon the ſcrew D E, and to hold it right to the oppoſite ſides of the concave ſcrews at *l*, *m*. To prevent any motion lengthways in the ſcrew D E, its tapering point D turns in a hollow point at the end of an oppoſite ſcrew *z*, which working through a fixt block at *z*, holds up the ſhoulder of the long ſcrew D E, againſt the back of the index-plate, where its neck is inſerted.

The two indexes upon the plate E F ſhew the number of revolutions and parts of a revolution of the ſcrew D E, anſwering to the interval of the ſights *g h*, *i k*. In the outward plate there is a circular ſlit *α β γ*, which diſcovers part of the diviſions upon the circumference of an inner plate, turned about a centre by two wheels and pinions within: ſo that for every revolution of the ſcrew and index E F, which ſhews the parts of it, one diviſion upon the plate *α β γ*, paſſes by a fixt pointer at *β*; which ſhews the number of revolutions anſwering to the interval of the ſights *g h*, *i k*.

This *micrometer* has lately received a very great improvement by an ingenious contrivance of the reverend Mr. James Bradley, profeſſor of Aſtronomy, at Oxford, for turning it in its own plane about the interſection *δ* of the fixt ſight *g h* and of the tranſverſe wire *b e*, without ſtirring the teleſcope: which is thus executed. Upon the backſide of the main-plate turned upwards, and here repreſented by the parallelogram G H I K, *fig. 46.* there is laid ſuch another plate L M N O, of the ſame breadth and thickneſs but ſomewhat ſhorter; in the middle of which there is an oblong hole, anſwering to that other in the lower plate, but ſomewhat larger; being terminated at its ſides by the ſtraight lines *ε ζ*, *π ϱ*, and at its ends by the concave arches *ε π*, *ζ ϱ*, whoſe common centre is the

the point δ abovementioned. The concave arch $\iota\theta$ slides round this centre againſt a concentric convex arch of an annular plate $\lambda\mu\nu$; ſomewhat longer than the concave arch, of the ſame thickneſs as the upper parallelogram, and ſtrongly ſcrewed to the under one, round that end of the hole which is neareſt to the centre δ: and at the ſame time the other concave arch $\xi\kappa\eta$ ſlides alſo againſt another concentric convex arch $\circ\pi$, of another annular plate juſt as thick as the upper parallelogram, and ſtrongly ſcrewed to the under one. This convex arch $\circ\pi$ is ſhorter than the contiguous concave one $\xi\kappa\eta$, to give room for the circular motion of the plates; which are held together by two annular plates ſimilar to $\lambda\mu\nu$ and $\circ\pi$, but ſomewhat broader, to cover the coincident arches, when laid over them, and ſcrewed down to the reſpective annular plates underneath. The circular motion upon theſe arches about their centre δ, is gradually given to the upper parallelogram by an endleſs ſcrew $\rho\sigma$, having an axis $\sigma\tau$ laid croſs the end of the under parallelogram, and turning upon a point at one end, and in a collar at the other, both fixt to the under plate; while the ſpiral thread ρ, moves the teeth of a braſs arch fixt at τ, to the end of the upper parallelogram.

To hold the micrometer in the tube of a teleſcope, along each ſide of the upper parallelogram there is fixt a long braſs plate about an inch broad; having its oppoſite ſides bent contrary ways, ſo as to form two oppoſite ledges, about one-eighth of an inch broad, at right angles to the intermediate part of the plate, as repreſented in the figure. One of the ledges of each plate is placed inwards along the ſides of the upper parallelogram, and is firmly fixt to it by ſeveral ſcrews. The figure $\phi\chi\psi\omega$ repreſents one of the equal and oppoſite holes cut in the ſides of a ſquare tube, through which the *micrometer* is put; the notches $\phi\chi$ being made to receive the ledges of the ſide-plates, to keep the plane of the *micrometer* perpendicular to the tube at a juſt diſtance from the object-glaſs. Which diſtance being once determined by trials, as above explained, muſt be kept invariable in all obſervations, by ſtops or pins, if the tube conſiſts of two or more joints that draw in and out.

The meaſures of the *micrometer*.

	Inches.
The length of the plate AB	8,0
Its breadth MN	3,9
Its thickneſs	0,$\frac{1}{4}$
Length of the hole be	3,5
Its breadth $gh=\delta\varepsilon$	2,2
Breadth of the hole in the other plate at $\xi\kappa$	2,6
Length of the ſcrew DE	5,5
Its thickneſs	0,3
The line Ab	1,0
The interval $lm=wx$	3,0
Length of the ſide cheeks	4,5
Their breadth	0,8
Their ledges	0,2
Diameter of the index-plate	3,1
Its thickneſs (being double with two wheels within)	0,3
The greateſt opening of the ſights gh, $ik=\delta\varepsilon$	2,2

Threads of the ſcrew in an inch, 40

The inch is divided by the index-plates into 40 times 40, or 1600 equal parts. Inſtead of the braſs ſights gh, ik, two others, with parallel wires may be ſcrewed on at pleaſure.

When the ſight-plates are made to coincide, the two indexes of the revolutions and their parts muſt be ſet to the beginning of the numerations upon the index-plates. Then as the ſights are opened, it is evident from the make of a ſcrew, that the numbers of revolutions will be as the intervals of the ſights, and conſequently as the angles ſubtended by them at the centre of the object-glaſs; the intervals being inſenſibly different from the arches that meaſure theſe ſmall angles. Therefore, when any one angle correſponding to a given number of revolutions, is determined by experiment, an angle correſponding to any other number of revolutions may be found by the rule of three. And thus may tables be made to ſhew by inſpection the number of minutes and ſeconds in an angle anſwering to any given number of revolutions and parts.

To determine ſome one angle, the larger the better, becauſe the ſame error in the determination will be proportionably ſmaller in a given angle deduced from it; fix the teleſcope upon any known ſtar in the equator, or very near it, and open their ſights to their utmoſt limit and note the number of revolutions of the ſcrew. Then by a pendulum-clock obſerve the interval of time in the ſtar's tranſit over the given interval of the ſights, and having turned it into minutes and ſeconds of an arch, they are the meaſure of the angle required. But if the ſtar be remote from the equator, the number of minutes and ſeconds thus found, muſt be diminiſhed in the ratio of the radius to the ſine of the ſtar's diſtance from the pole. To this *micrometer* Dr. Bradley applied an ingenious contrivance, whereby it is adapted for taking the difference of right aſcenſion and declination of ſuch objects as are at a greater diſtance than the teleſcope will take in at once, but which paſs through the aperture of it at different times. Let ABC, *fig.* 47. repreſent a flat ring of braſs, fixed in the focus of the teleſcope; and *abc* a ſmaller concentric ring lodged in a circular groove turned within the larger, and kept in the groove by three ſmall plates of braſs fixed to the outward ring, and extended over the edge of the inner one. Upon the inner ring is fixt a concentric arch of a wheel *de*, having teeth cut in its convexity, which are driven round by the threads of an endleſs ſcrew, whoſe axis DEF turns in a collar at E and upon a point at F, both fixt to the outward ring. The hairs gh, ik croſs at right angles in f the centre of the rings; and when the teleſcope is ſo fixt that the image of the ſtar falls upon f, let it move along any line fg, and by turning the ſcrew DEF, and by conſequence the hair fk, about the fixt point f till it touches the ſtar at g, it will then coincide with the tract of the ſtar's motion; and then all other ſtars will move parallel to it as was required. To find the difference of declination of two ſtars, he obſerves the times of their appulſes to the edges of two ſlender braſs bars gio, gkp, fixt to the inner ring, and equally inclined to its diameter gb in ſuch angles that the perpendiculars fi, fk, on each ſide of fg, ſhall be ſeverally equal to half fg; and conſequently that the whole baſe ik, of the equicrural triangle igk, ſhall be equal to its perpendicular height fg; and by conſequence that the difference of any two baſes if, km ſhall be equal to fm, the difference of their heights; ſo that the difference of the times of the tranſits of two ſtars over theſe baſes, may give the difference of their declinations. Smith's Optics, art. 876, &c.

Mr. Caſſini firſt made uſe of four croſs hairs or threads, interſecting one another at half right angles, for determining the difference of right aſcenſions and declinations of objects near the ſame parallel: but the *micrometer*, according to its later improvements, will anſwer this purpoſe with greater exactneſs. Mr. Maſkelyne has publiſhed directions for the uſe of it, extracted from Dr. Bradley's papers, in the Philoſ. Tranſ. vol. lxii. art. 6. p. 46, &c.

A conſiderable improvement with regard to the *micrometer*, was communicated to the Royal Society, in 1743, by Mr. Servington Savery, an account of which, extracted from the minutes by Mr. Short, was publiſhed in the Phil. Tranſ. for 1753, vol. xlviii. art. 26. The firſt hint of ſuch a *micrometer* was ſuggeſted by M. Roemer, in 1675: and M. Bouguer propoſed a ſimilar conſtruction to that of Mr. Savery, in 1748, for which ſee HELIOMETER. The late Mr. Dollond made a farther improvement in this kind of *micrometer*, an account of which was given to the Royal Society by Mr. Short, and publiſhed in the Phil. Tranſ. vol. xlviii. art. 27. Inſtead of two object-glaſſes, he uſed only one, which he neatly cut into two ſemi-circles, and fitted each ſemi-circle in a metal frame, ſo that their diameters ſliding in one another, by means of a ſcrew, may have their centers ſo brought together as to appear like one glaſs, and ſo form one image; or by their centers receding, may form two images of the ſame object: it being a property of ſuch glaſſes, for any ſegment to exhibit a perfect image of an object, although not ſo bright as the whole glaſs would give it. If proper ſcales are fitted to this inſtrument, ſhewing how far the centers recede, relative to the focal length of the glaſs, they will alſo ſhew how far the two parts of the ſame object are aſunder, relative to its diſtance from the object-glaſs; and conſequently give the angle under which the diſtance of the parts of that object are ſeen. This divided object-glaſs *micrometer*, which was applied by the late Mr. Dollond to the object end of a reflecting teleſcope has been with equal advantage adapted by his ſon to the end of an achromatic teleſcope, is ſo eaſy of uſe, and affords ſo large a ſcale, that it is generally looked upon by aſtronomers as the moſt convenient and exact inſtrument for meaſuring ſmall diſtances in the heavens. However, the common *micrometer* is peculiarly adapted for meaſuring differences of right aſcenſion, and declination of celeſtial objects, but leſs convenient and exact for meaſuring their abſolute diſtances; whereas the object-glaſs *micrometer* is peculiarly fitted for meaſuring diſtances, but has been generally ſuppoſed improper for meaſuring differences of right aſcenſion and declination. But Mr. Maſkelyne has found that the latter may be applied with very little trouble, and ſmall additional expence, to this other purpoſe as well as the former; and he has furniſhed the directions neceſſary to be followed when it is uſed in this manner. The addition

requiſite

requiſite for this purpoſe is a cell, containing two wires, interſecting each other at right angles, placed in the focus of the eye-glaſs of the teleſcope, and moveable round about, by the turning of a button. For the deſcription of this apparatus, together with the method of applying and uſing it, we ſhall refer to Mr. Maſkelyne's paper on the ſubject, in the Phil. Tranſ. vol. lxi. part ii. art. 49, p. 536, &c.

After all, the uſe of the object-glaſs *micrometer* is attended with difficulties, ariſing from the alterations in the ſocus of the eye, which are apt to cauſe it to give different meaſures of the ſame angle at different times. In order to obviate theſe difficulties, Mr. Maſkelyne, in 1776, contrived a priſmatic *micrometer*, or a *micrometer* conſiſting of two achromatic priſms, or wedges, applied between the object-glaſs and eye-glaſs of an achromatic teleſcope, by moving of which wedges nearer to or farther from the object-glaſs, the two images of an object produced by them appeared to approach to or recede from each other, ſo that the focal length of the object-glaſs becomes a ſcale for meaſuring the angular diſtance of the two images. The rationale and uſe of this *micrometer* are explained in the Phil. Tranſ. vol. lxvii. part ii. art. 36. p. 799, &c. A ſimilar invention by the abbé Rochon, and improved by the abbé Boſcovich, was alſo communicated to the Royal Society, and publiſhed in the ſame volume of the Tranſactions, art. 35, p. 789, &c. Mr. Ramſden, an ingenious optician, has lately deſcribed two new *micrometers*, which he has contrived with a view of remedying the defects of the object-glaſs *micrometer*. One of theſe is a catoptric *micrometer*, which, beſide the advantage it derives from the principle of reflection, of not being diſturbed by the heterogeneity of light, avoids every defect of other *micrometers*, and can have no aberration, not any defect ariſing from the imperfection of materials, or of execution; as the extreme ſimplicity of its conſtruction requires no additional mirrors or glaſſes to thoſe required for the teleſcope; and the ſeparation of the image being effected by the inclination of the two ſpecula, and not depending on the ſocus of any lens or mirror, any alteration in the eye of an obſerver cannot affect the angle meaſured. It has peculiar to itſelf the advantages of an adjuſtment, to make the images coincide in a direction perpendicular to that of their motion; and alſo of meaſuring the diameter of a planet on both ſides of the zero, which will appear no inconſiderable advantage to obſervers who know how much eaſier it is to aſcertain the contact of the external edges of two images than their perfect coincidence. A (*Tab.* III. *Optics*, *fig.* 48.) repreſents the ſmall ſpeculum of a reflecting teleſcope of Caſſegrain's conſtruction, to which this *micrometer* is adapted, divided into two equal parts; one of which is fixed on the end of the arm B; the other end of the arm is fixed on a ſteel axis X, which croſſes the end of the teleſcope C. The other half of the mirror A is fixed on the arm D, which arm at the other end terminates in a ſocket *y*, that turns on the axis X; both arms are prevented from bending by the braces *aa*. G repreſents a double ſcrew, having one part *e* cut into double the number of threads in an inch to that of the part *g*; the part *e* having a hundred threads in one inch, and the part *g* fifty only. The ſcrew *e* works in a nut F in the ſide of the teleſcope, while the part *g* turns in a nut H, which is attached to the arm B; the ends of the arms B and D, to which the mirrors are fixed, are ſeparated from each other by the point of the double ſcrew preſſing againſt the ſtud *b*, fixed to the arm D, and turning in the nut H on the arm B. The two arms B and D are preſſed againſt the direction of the double ſcrew *e g* by a ſpiral ſpring within the part *m*, by which means all ſhake or play in the nut H, on which the meaſure depends, is entirely prevented.

From the difference of the threads on the ſcrew at *e* and *g* it is evident, that the progreſſive motion of the ſcrew through the nut will be half the diſtance of the ſeparation of the two halves of the mirror, and conſequently the half mirrors will be moved equally in contrary directions from the axis of the teleſcope C.

The wheel V fixed on the end of the double ſcrew has its circumference divided into 100 equal parts, and numbered at every fifth diviſion with 5, 10, &c. to 100, and the index I ſhews the motion of the ſcrew with the wheel round its axis, while the number of revolutions of the ſcrew is ſhewn by the diviſions on the ſame index. The ſteel ſcrew R may be turned by the key S, and ſerves to incline the ſmall mirror at right angles to the direction of its motion.

The other *micrometer* invented and deſcribed by Mr. Ramſden, is ſuited to the principle of refraction. This *micrometer* is applied to the erect eye-tube of a refracting teleſcope, and is placed in the conjugate ſocus of the firſt eye-glaſs; in which poſition, as the image is conſiderably magnified before it comes to the *micrometer*, any imperfection in its glaſs will be magnified only by the remaining eye-glaſſes, which in any teleſcope ſeldom exceeds five or ſix times; and beſides, the ſize of the *micrometer* glaſs will not be the $\frac{1}{1000}$th part of the area which would be required, if it were placed at the object-glaſs; and yet the ſame extent of ſcale is preſerved, and the images are uniformly bright in every part of the field of the teleſcope. This *micrometer* is repreſented *Tab.* III. *Optics*, *fig.* 49. A is a convex or concave lens divided into two equal parts by a plane acroſs its center; one of theſe ſemi-lenſes is fixed in a frame B, and the other in the frame E, which two frames ſlide on a plate H, and are preſſed againſt it by thin plates *a a*: the frames B and E are moved in contrary directions by turning the button D; L is a ſcale of equal parts on the frame B; it is numbered from each end towards the middle with 10, 20, &c. There are two verniers on the frame E, one at M, and the other at N, for the conveniency of meaſuring the diameter of a planet, &c. on both ſides of the zero. The firſt diviſion on both theſe verniers coincides at the ſame time with the two zeros on the ſcale L, and, if the frame is moved towards the right, the relative motion of the two frames is ſhewn on the ſcale L by the vernier M; but if the frame B be moved towards the left, the relative motion is ſhewn by the vernier N. This *micrometer* has a motion round the axis of viſion, for the conveniency of meaſuring the diameter of a planet, &c. in any direction, by turning an endleſs ſcrew F, and the inclination of the diameter meaſured with the horizon is ſhewn on the circle *g* by a vernier on the plate V. The teleſcope may be adjuſted to diſtinct viſion by means of an adjuſting ſcrew, which moves the whole eye-tube with the *micrometer* nearer or farther from the object-glaſs, as teleſcopes are generally made; or the ſame effect may be produced in a better manner, without moving the *micrometer*, by ſliding the part of the eye-tube *m* on the part *n*, by help of a ſcrew or pinion. The *micrometer* is made to take off occaſionally from the eye-tube, that the teleſcope may be uſed without it. Phil. Tranſ. vol. lxix. part ii. art. 27.

The *micrometer* has not only been applied to teleſcopes, and employed for aſtronomical purpoſes; but there have been various contrivances for adapting it to microſcopical obſervations. Mr. Leeuwenhoek's method of eſtimating the ſize of ſmall objects was by comparing them with grains of ſand, of which a hundred in a line took up an inch. Theſe grains he laid upon the ſame plate with his objects, and viewed them at the ſame time. Dr. Jurin's method was ſimilar to this; for he found the diameter of a piece of fine ſilver wire, by wrapping it as cloſe as he could about a pin, and obſerving how many rings made an inch; and he uſed this wire in the ſame manner as Leeuwenhoek uſed his ſand. Dr. Hooke uſed to look upon the magnified object with one eye, while, at the ſame time, he viewed other objects, placed at the ſame diſtance, with the other eye. In this manner he was able, by the help of a ruler, divided into inches and ſmall parts, and laid on the pedeſtal of the microſcope to caſt, as it were, the magnified appearance of the object upon the ruler, and thus exactly to meaſure the diameter which it appeared to have through the glaſs; which being compared with the diameter as it appeared to the naked eye, eaſily ſhewed the degree in which it was magnified. A little practice, ſays Mr. Baker, will render this method exceedingly eaſy and pleaſant.

Mr. Martin, in his Optics, recommends ſuch a *micrometer* for a microſcope as had been applied to teleſcopes; for he adviſes to draw a number of parallel lines on a piece of glaſs, with the fine point of a diamond, at the diſtance of $\frac{1}{20}$ of an inch from one another, and to place it in the focus of the eye-glaſs. By this method, Dr. Smith contrived to take the exact draught of objects viewed by a double microſcope; for he adviſes to get a lattice, made with ſmall ſilver wires or ſquares, drawn upon a plain glaſs by the ſtrokes of a diamond, and to put it into the place of the image, formed by the object-glaſs. Then by tranſferring the parts of the object, ſeen in the ſquares of the glaſs or lattice upon ſimilar correſponding ſquares drawn on paper, the picture may be exactly taken. Mr. Martin alſo introduced into compound microſcopes another *micrometer*, conſiſting of a ſcrew. See both theſe methods deſcribed in his Optics, p. 277.

The moſt minute and accurate diviſion of any ſcale which the editor has ever ſeen, is performed by Mr. Coventry of Southwark. The *micrometers* of his conſtruction are parallel lines drawn on glaſs, ivory, or metal, from the 10th to the 100th of an inch. Theſe may be applied to microſcopes, for meaſuring the ſize of minute objects, and the magnifying power of the glaſſes; and to teleſcopes, for meaſuring the ſize and diſtance of objects,

and the magnifying power of the inſtrument. For meaſuring the ſize of an object in a ſingle microſcope, lay it on a *micrometer*, whoſe lines are ſeen magnified in the ſame proportion with it, and give at one view the real ſize of the object. For meaſuring the magnifying power of the compound microſcope, the beſt and moſt ready method is the following. On the ſtage in the focus of the object glaſs, lay a *micrometer*, conſiſting of an inch divided into one hundred equal parts; count how many diviſions of the *micrometer* are taken into the field of view; then lay a two-foot rule parallel to the *micrometer*: fix one eye on the edge of the field of light, and the other eye on the end of the rule, which move, till the edge of the field of light and the end of the rule correſpond; then the diſtance from the end of the rule to the middle of the ſtage will be the half of the diameter of the field: e. gr. if the diſtance be ten inches, the whole of the diameter will be twenty, and the number of the diviſions of the *micrometer* contained in the diameter of the field, is the magnifying power of the microſcope. Thus, ſuppoſe the number of diviſions ſeen in the *micrometer* to be $\frac{1}{40}$ths, and that the diameter of the field meaſures with the rule twenty inches; the $\frac{1}{40}$th of 20 inches is 40, which is the diameter of the field; $40 \times 40 = 1600$ the ſuperficies, and $1600 \times 40 = 64000$, the magnified cube of the object: in like manner each object-glaſs or magniſier muſt be proved, and a table kept of their ſeveral magnifying powers. For meaſuring the height and diſtance of objects by a *micrometer* in the teleſcope, ſee TELESCOPE.

Mr. Adams has applied a *micrometer*, which inſtantly ſhews the magnifying power of any teleſcope.

MICROPHONES, inſtruments contrived to magnify ſmall ſounds, as *microſcopes* do ſmall objects.

MICROPUS, in *Botany*. See *Baſtard* CUDWEED.

MICROSCOPE, *Μικροσκοπιον*, formed of *μικρος*, *ſmall*, and *σκεπτομαι*, *I conſider*; an optical inſtrument, by means whereof very minute objects are repreſented exceedingly large, and viewed very diſtinctly, according to the laws of refraction or reflection.

Microſcopes are properly diſtinguiſhed into ſimple, or *ſingle*; and compound, or *double*.

MICROSCOPES, *ſingle*, are thoſe which conſiſt of a ſingle lens, or a ſingle ſpherule.

MICROSCOPES, *compound*, conſiſt of ſeveral lenſes duly combined. As optics have been improved, other varieties have been contrived, in the ſorts of *microſcopes*: hence *reflecting microſcopes*, *water microſcopes*, &c.

When, and by whom, *microſcopes* were firſt invented, is not certainly known. Huygens tells us, that one Drebbell, a Dutchman, had the firſt *microſcope*, in the year 1621, and that he was reputed the inventor of it: though F. Fontana, a Neapolitan, in 1646, claims the invention to himſelf, but dates it from the year 1618. As a teleſcope inverted is a *microſcope*, the diſcovery might eaſily enough have ariſen from thence.

Nothing more is certain concerning *microſcopes*, than that they were firſt uſed in Germany about the year 1621. According to Borellus, they were invented by Zacharias Janſen, in conjunction with his ſon, who preſented the firſt *microſcopes* they had conſtructed to prince Maurice, and Albert, archduke of Auſtria. William Borell, who gives this account in a letter to his brother Peter, ſays, that when he was ambaſſador in England, in 1619, Cornelius Drebell ſhewed him a *microſcope*, which he ſaid, was the ſame that the archduke had given him, and had been made by Janſen himſelf. Borellus de vero Teleſcopii inventore. p. 35. See LENS.

MICROSCOPES, *foundation and theory of ſingle*. If an object AB (*Tab.* IV. *Optics*, *fig.* 50.) be placed in the focus of a ſmall convex lens, or a ſimple *microſcope* DE, and the eye be applied cloſe to the other ſide of the *microſcope*, *the object will be ſeen diſtinct, in an erect ſituation, and magnified in the ratio of the diſtance of the focus to the diſtance wherein objects are to be placed to be ſeen diſtinctly by the naked eye.*

For the object AB being placed in the focus of the convex lens DE, the rays iſſuing from the ſeveral points thereof, after refraction, will be parallel to each other: conſequently, the eye will ſee it *diſtinctly*, by virtue of what is proved under the word TELESCOPE.

Farther, ſince one of the rays AF, proceeding from the point A, after refraction, becomes parallel to the incident ray; and therefore, ſetting aſide the thickneſs of the lens, is found directly againſt it; and the ſame holds true of all the other rays carried to the eye; the rays AF and BF, to which the reſt coming from A and B are parallel, will enter the eye in the ſame manner as if they entered without paſſing through the lens; and will therefore appear erect, as if the lens were away.

Laſtly, it is manifeſt, that the object AB will be ſeen under the ſame angle as if viewed by the naked eye: but ſince it appears very diſtinct, whereas to the naked eye, at the ſame diſtance, it would appear extremely confuſed; it is the ſame thing as if the object ſhould ſeem removed to the diſtance FH, wherein it is viewed with equal diſtinctneſs, and under the ſame angle: the diameter of the object AB, therefore, will be to the apparent diameter IK, as FC to FH, i. e. as the diſtance of the focus of the lens to the diſtance wherein an object is to be placed, in order to view it diſtinctly. Since, therefore, the interpoſition of the glaſs has no other effect than to render the appearance diſtinct, by helping the eye to increaſe the refraction of the rays in each pencil, it is plain that the greater apparent magnitude is entirely owing to a nearer view than could be taken by the naked eye.

Huygens, in Dioptrics, prop. lix. p. 222, takes it for granted, that an object, ſeen with the naked eye, is then in its utmoſt diſtinctneſs when ſeen at the diſtance of eight digits, or tenths of a foot; which agrees pretty near with the obſervations of others; who make the neareſt limit of diſtinct viſion to be eight inches. So that if the glaſs be a ſmall round globule, whoſe focal diſtance is $\frac{1}{20}$ of an inch, this globule will magnify as 8 to $\frac{1}{20}$, or as 160 to 1.

MICROSCOPES, *laws of ſingle*. 1. Simple *microſcopes* magnify the diameter of the object AB in the ratio of the diſtance of the focus FC to an interval of eight digits: v. gr. if the ſemidiameter of a lens, equally convex on both ſides, be half a digit, and conſequently its focal diſtance the ſame: AB : IK :: $\frac{1}{2}$: 8 :: 1 : 16; that is, the diameter of the object will be increaſed in a ſedecuple proportion, or as ſixteen to one. 2. Since the diſtance FH is conſtant, viz. eight digits; by how much the diſtance of the focus FC is ſmaller, ſo much the ſmaller ratio will it have to FH; conſequently, the diameter of the object will be ſo much the more magnified. 3. Since, in plano-convex lenſes, the diſtance of the focus is equal to the diameter; and, in lenſes equally convex on both ſides, to the ſemidiameter: ſimple *microſcopes* will enlarge the diameter ſo much the more, as they are ſegments of ſmaller ſpheres. 4. If the diameter of the convexities of a plano-convex lens, and a lens convex on both ſides, be the ſame, viz. = 1; the diſtance of the focus of the firſt will be 1, of the ſecond $\frac{2}{3}$: conſequently, the ſemidiameter of the object AB will be to the apparent one, in the firſt caſe, as 1 to 8; in the latter, as $\frac{2}{3}$ to 8; i. e. as 1 to 16. A lens, therefore, convex on both ſides, magniſies twice as much as a plano-convex lens.

As the whole depends on the juſt and ſteady ſituation of objects with regard to the lens, various methods have been contrived to that end; whence we have ſeveral different kinds of ſingle *microſcopes*. The moſt ſimple is as follows.

1. AB (*fig.* 51.) is a little tube, to one of whoſe baſes, BC, is fitted a plain glaſs, to which an object, viz. a gnat, wing of an inſect, down, or the like, is applied; to the other baſe, AD, at a proper diſtance from the object, is applied a lens convex on both ſides, whoſe ſemidiameter is about half an inch; the plain glaſs is turned to the ſun, or the light of a candle, and the object is ſeen magnified; and, if the tube be made to draw out, lenſes of different ſpheres may be uſed.

Again, a lens, convex on both ſides, is incloſed in a cell AC, (*fig.* 52.) and by a ſcrew H is there faſtened through the pedeſtal CD paſſes a long ſcrew, by means whereof, and the female ſcrew I, a ſtyle or needle, fixed perpendicular to its extreme, is kept firm at any diſtance from the lens: in E is a little tube, on which, and on the point G, the various objects are to be diſpoſed: thus there may be lenſes of various ſpheres applied.

2. But the *microſcope* which is found to anſwer the end beſt, is Mr. Wiſſon's pocket *microſcope*, which has nine different magnifying glaſſes, eight of which may be uſed with two different inſtruments, for better applying them to various objects. One of theſe inſtruments is repreſented at AABB (*fig.* 53.) and is made of ivory or braſs; it has three thin braſs plates at E, and a ſpiral ſpring of ſteel-wire H within it; to one of the thin plates of braſs is fixed a piece of leather F, with a ſmall furrow, G, both in the leather and braſs to which it is fixed: in one end of this inſtrument there is a long ſcrew D, with a convex glaſs C, placed in the end of it: in the other end of the inſtrument there is a hollow ſcrew *e o*; wherein any of the magnifying glaſſes, M, are ſcrewed, when they are to be made uſe of. The nine different magnifying glaſſes are all ſet in ivory, eight of which are ſet in the manner expreſſed at M. The greateſt magniſier is marked upon the ivory, wherein it is ſet, with N° 1, the next N° 2, and ſo on to N° 8; the ninth glaſs is not marked, but is ſet in the manner of a little barrel box of ivory, as at *b*. At *ee* is a flat piece of ivory, whereof there are eight belonging to this ſet of microſcopes (though any one

who has a mind to keep a regiſter of objects may have as many of them as he pleaſes; in each of them there are three holes *fff*, wherein three or more objects are placed between two thin glaſſes, or talcs, when they are to be uſed with the greater magnifiers.

The uſe of this inſtrument AABB is this. Having taken the handle W from the inſtrument in *fig.* 54. and ſcrewed it upon the button S, take one of your flat pieces of ivory *ee*, or fliders (if you pleaſe to call them ſo), and ſlide it betwixt the two thin plates of braſs at E, through the body of the *microſcope*, ſo that the object you intend to look upon be juſt in the middle; remarking that you put that ſide of the plate *ee*, where the braſs rings are, fartheſt from the end AA; then you are to ſcrew into *oo* (the hollow ſcrew in the end of the body of your *microſcope*) the 3d, 4th, 5th, 6th, or 7th magnifying glaſs M; which being done, put the end AA cloſe to your eye, and while you are looking through your magnifying glaſs upon the object, you are to ſcrew in or out the long ſcrew D, which moving round upon the leather F, held tight to it by the ſpiral wire H, will bring your object to the true diſtance; which you will know by ſeeing it clearly and diſtinctly: but ſince in the greater magnifiers you can ſee but a ſmall part of the object, viz. the legs or claws of a flea; while you are looking upon any part of the object, if you take hold of the end of the plate or ſlider *ee*, whereon the object lies, and move it gently, you may ſee the whole object ſucceſſively, or any part of the object you pleaſe; and if that part of the object you deſign to look upon be out of the true diſtance, remember your end ſcrew D, can always bring it in, by ſcrewing it one way or the other.

After this manner may be ſeen all tranſparent objects, duſts, liquids, chryſtals of ſalts, ſmall inſects, ſuch as fleas, mites, &c. If they be inſects that will creep away, or ſuch objects as one intends to keep, they may be placed between the two regiſter glaſſes *ff*. For by taking out (with the point of a pen-knife or ſmall plyers) the ring that keeps in the glaſſes *ff*, where the object lies, they will fall out of themſelves; ſo you may lay the object between the two hollow ſides of them, and put the ring in as it was before; but if the objects be duſts or liquids, a ſmall drop of the liquid, or a little of the duſt laid on the outſide of the glaſs *ff*, and applied as before, will be ſeen very eaſily.

As to the firſt, ſecond, and third magnifying glaſſes, being marked with a + upon the ivory wherein they are ſet, they are only to be uſed with thoſe plates or fliders that are alſo marked with a +, wherein the objects are placed between two thin tales; becauſe the thickneſs of the glaſſes in the other plates or fliders, hinder the object from approaching to the true diſtance from theſe greater magnifiers. But the manner of uſing them is the ſame with the former; only remember to be careful when you put in or pull out the plate or ſlider *ee*, whereon the object lies, or move it from one object to another, not to let it rub your magnifying glaſs; which is done by unſcrewing a little the end ſcrew D, when you put in or pull out your plate, or move it from one object to another.

For ſeeing the circulation of the blood at the extremities of the arteries and veins, in the tranſparent parts of fiſhes tails, &c. there are two glaſs tubes, the one bigger and the other leſſer, as expreſſed at *g g*, wherein the fiſh is to be put; when theſe tubes are to be uſed, you are to unſcrew the end ſcrew D in the body of the *microſcope*, until the tube *g g* can be received eaſily into that little cavity G of the braſs plate faſtened to the leather F, under the other two thin plates of braſs at E. When the tail of your fiſh lies flat to the glaſs tube, ſet it oppoſite to your magnifying-glaſs, and by ſcrewing in or out your end ſcrew D, as is ſaid before, you may eaſily bring it to the true diſtance, and ſee the blood circulate with great pleaſure.

If you would ſee the blood circulate in a frog's foot, chooſe ſuch a frog as will juſt go into your tube; then with a little ſtick expand the hinder foot of the frog, and apply it cloſe to the ſide of the tube, obſerving that no part of the frog hinders the light from coming on its foot; and when you have it at the juſt diſtance, by means of the ſcrew D, as aboveſaid, you will ſee the rapid motion of the blood in its veſſels, which are very numerous, in the tranſparent thin membrane that is between the frog's toes. For this object the 4th and 5th magnifiers will do very well; but you may ſee the circulation in the tails of water-newts with the 6th and 7th glaſſes, becauſe the globules of the blood of thoſe newts are as big again as the globules of the blood of frogs or ſmall fiſh, as has been taken notice of in N° 280 of the Philoſophical Tranſactions, p. 1184.

The circulation cannot ſo well be ſeen by the firſt, ſecond, and third magnifiers, becauſe the thickneſs of the glaſs tube wherein the fiſh lies, hinders the approach of the object to the focus of the magnifying glaſs.

The other inſtrument (*fig.* 54.) is made of braſs or prince's metal, with joints PPP to turn eaſily any way, and with a ſmall pair of tongs G G, which open at the points K, by preſſing together the two heads of the pins II, for taking up of objects. At the other end of theſe tongs G G, is ſcrewed on a round piece of black wood H, with a piece of ivory let into it, for placing opake objects on, according to their difference of colour. Upon the end L there is a ſcrew, upon which the glaſs *b* ſet in the barrel-box may be ſcrewed. When the other glaſſes are to be uſed, there is a ring R of braſs to be ſcrewed on the end L, into which ring all the other glaſſes M, may be ſcrewed. So when any object is taken up in the points of the tongs K, or laid upon the other end H, it may very eaſily (as one who ſees the inſtrument will perceive) be applied to the true focal diſtance of any of the glaſſes M, by the help of the joints PPP, and by means of the ſcrew C, with the wheel D, which being regulated by a ſpring N, will bring the object to the exact diſtance for diſtinct viſion.

The glaſs placed in the manner of a barrel-box at *b*, is only to be uſed with the braſs inſtrument (or in your hand) being the leaſt magnifier for greater objects, ſuch as flies and common inſects, &c. remembering to put the hole *b* next to your eye.

In the viewing objects, one ought to be careful not to hinder the light from falling upon them, by the hat, peruke, or any other thing, eſpecially in looking at opake objects; for nothing can be ſeen with the beſt of glaſſes, unleſs the object be at a due diſtance, with a ſufficient light. The beſt lights for the plates or fliders, where the object lies between the two glaſſes, is a clear ſky-light, or where the ſun ſhines on any white thing, or the reflection of the light from a looking-glaſs. The light of a candle is likewiſe good for the viewing of very ſmall objects, though it be a little uneaſy to thoſe who are not practiſed in *microſcopes* to find it out. The only uſe of the convex lens at C is to collect the light into a narrower compaſs where it falls upon the object, after it has paſſed through a moderate hole in the leather F.

For the convenience of thoſe who would draw, or make any ſketches or deſigns of *microſcopical* objects, they may alſo have a pedeſtal to fix the two inſtruments above deſcribed, and make them ſtationary to any convenient light. This pedeſtal may be placed on a table, and after the object and light are fixed, as many perſons as pleaſe may view the object, without any trouble or difficulty in finding the light. Phil. Tranſ. abr. vol. iv. p. 199, &c. What has been ſaid hitherto, is to be underſtood of *lenticular microſcopes*; for *ſpherical* ones, their doctrine will be underſtood from what follows.

If an object AB (*fig.* 55.) be placed in the focus of a glaſs ſpherule F, and the eye be behind it, v. gr. in the focus G; the object will be ſeen diſtinct, in an erect ſituation, and magnified, as to its diameter, in a ratio of $\frac{1}{4}$ of the diameter EI, to the diſtance at which objects are to be placed to be ſeen diſtinctly with the naked eye.

The firſt part of the propoſition is proved in the ſame manner of ſpheres, as of lenſes. As, then, a good eye ſees an object diſtinctly at the diſtance of eight digits, a glaſs ſpherule will enlarge the diameter of an object in a ratio of $\frac{1}{4}$ of the diameter to 8 digits. Suppoſe, then, the diameter of the ſpherule EI $= \frac{1}{20}$ of a digit, CE will be $= \frac{1}{20}$, and FE $= \frac{1}{16}$; and therefore FC $= \frac{1}{16} + \frac{1}{16} = \frac{1}{8}$. Conſequently, the true diameter of an object to its apparent one is in the ratio of $\frac{1}{20}$ to 8; i. e. as 3 to 320, or as 1 to 106 nearly.

Now a lens, convex on both ſides, increaſes the diameter in a ratio of the ſemidiameter to the ſpace of eight digits; wherefore $\frac{1}{4}$ having a leſs ratio to 8 than $\frac{1}{3}$, if a lens and a ſphere have the ſame diameter, the former will magnify more than the latter; and, pretty much after the ſame manner, it may be ſhewn, that a ſphere, of a leſs diameter, magnifies more than another of a large one.

For the methods of caſting little glaſs ſpherules for MICROSCOPES, there are various. The firſt perſon who improved ſingle *microſcopes* by uſing ſmall globules of glaſs, made by melting them in the flame of a candle, was Hartſocker, who thus diſcovered the animalcula in ſemine maſculino, and laid the foundation of a new ſyſtem of GENERATION. Wolfius deſcribes the following method of making globules of this kind: a ſmall piece of very fine glaſs, ſticking to the wet point of a ſteel needle, is to be applied to the extreme bluiſh part of the flame of a lamp, or, which is better, to the flame of ſpirit of wine, to prevent its being blackened: being there melted, and run into a little round drop, it is to be removed from the flame, upon which it inſtantly ceaſes to be fluid; folding, then, a thin plate of braſs, and making very ſmall

ſmooth

smooth perforations, ſo as not to leave any roughneſs on the ſurfaces; and, farther, ſmoothing them over, to prevent any glaring, fit the ſpherule between the plates againſt the apertures, and put the whole in a frame, with objects convenient for obſervation.

Mr. Adams gives another method, thus: take a piece of fine window-glaſs, and raiſe it, with a diamond, into as many lengths as you think needful, not exceeding an eighth of an inch in breadth; then holding one of theſe lengths between the fore-finger and thumb of each hand, over a very fine flame, till the glaſs begins to ſoften, draw it out till it be as fine as a hair, and break; then, applying each of the ends into the pureſt part of the flame, you have two ſpheres preſently, which you may make larger, or leſs, at pleaſure: if they ſtay long in the flame, they will have ſpots; ſo they muſt be drawn out immediately after they are turned round. As to the ſtem, break it off as near the ball as poſſible; and, lodging the remainder of the ſtem between the plates, by drilling the hole exactly round, all the protuberances are buried between the plates: and the *microſcope* performs to admiration.

Mr. Butterfield, in the Phil. Tranſ. N° 141, recommends, for making glaſs globules clear and without ſpecks, the flame of a lamp, made with rectified ſpirit of wine, and inſtead of a cotton wick fine ſilver-wire, doubled like a ſkain of thread; then having beaten ſome fine glaſs to powder, and waſhed it clean, he directs to take a little of it upon the ſharp point of a ſilver needle, wetted with ſpittle, and to hold it in the flame, turning it about till it melts, and becomes quite round. When many globules are thus formed, he rubs them with ſoft leather; and having ſeveral ſmall pieces of thin braſs plates, twice as long as they are broad, he doubles them up into the form of a ſquare, and puſhes a fine hole through the middle of them; and having rubbed off the burr about the holes with a whetſtone, and blackened the inſide of the plates with the ſmoke of a candle, he places a globule between the two holes, and tacks the plates together with two or three rivets.

After theſe manners may ſpheres be made much ſmaller than any lens; ſo that the beſt ſingle *microſcopes*, or thoſe which magnify the moſt, are made thereof. For ſuppoſe the diameter of a ſpherule to be $\frac{1}{72}$ of a digit, the diſtance of its focus will be $\frac{1}{144}$; and therefore its real diameter to its apparent one, as $\frac{1}{144} + \frac{1}{144}$ that is, as $\frac{1}{144}$ to 8, or as 3 to 512; or, laſtly, as 1 to 170. The ſurface of an object, therefore, will be increaſed by it in the proportion of 1 to 28900, and its bulk in a ratio of 1 to 4913000.

M. Leeuwenhoeck and M. Muſchenbroeck have ſucceeded very well in ſpherical *microſcopes*; and the apparatus of the latter is much commended: but we forbear any deſcriptions thereof; it being eaſy for any, who conſiders the ſtructure of thoſe conſiſting of lenſes, to conceive how thoſe of ſpheres may be contrived.

M. Leeuwenhoeck's *microſcopes* were all ſingle ones; each of them conſiſting of a ſmall double convex glaſs ſet in a ſocket, between two ſilver plates, rivetted together, and pierced with a ſmall hole; and the object was placed on the point of a needle, ſo contrived, as to be placed at any diſtance from the lens. If the objects were ſolid, he faſtened them with glue; and if they were fluid, or, on other accounts, required to be ſpread on glaſs, he placed them on a ſmall piece of Muſcovy tale, or glaſs blown very thin, which he afterwards glued to his needle. He had, however, a different apparatus for viewing the circulation of the blood, which he could fix to the ſame *microſcopes*. Thoſe which he bequeathed to the Royal Society were contained in a ſmall Indian cabinet, in the drawers of which were thirteen little boxes or caſes, in each of which were two *microſcopes*, neatly fitted up in ſilver; and both the glaſs and the apparatus were made with his own hands. The greateſt magnifier among theſe enlarged the diameter of an object about 160 times. Phil. Tranſ. abr. vol. vi. p. 129, &c. Id. vol. viii. p. 121, &c.

The ſmalleſt globules, and conſequently the greateſt magnifiers for *microſcopes* that have yet been executed, were made by P. Di Torre of Naples, who, in 1765, ſent four of them to the Royal Society. The largeſt of them was only two Paris points in diameter, and is ſaid to magnify the diameter of an object 640 times; the ſecond was the ſize of one Paris point, magnifying the diameter 1280 times, and the third no more than one half of a Paris point, or the 144th part of an inch in diameter, and was ſaid to magnify the diameter of an object 2560 times, and conſequently the ſquare of ſuch diameter 6,553,600 times. But ſince the focus of a glaſs globule is at the diſtance of one-fourth of its diameter, and, therefore, that of the third globule of Di Torre, above mentioned, only the 576th part of an inch diſtant from the object, it muſt be with the utmoſt difficulty that globules ſo minute as theſe can be employed to any purpoſe: and Mr. Baker, to whoſe examination they were referred, conſiders them as matters of curioſity rather than of real uſe. Phil. Tranſ. vol. lv. p. 240. vol. lvi. p. 67, &c. For an account of obſervations made with theſe globules on the blood, ſee BLOOD.

MICROSCOPE, *water*. Mr. S. Gray, and, after him, Wolfius, and others, have contrived *water-microſcopes*, conſiſting of ſpherules, or lenſes of water, inſtead of glaſs, fitted up ſomewhat after the manner of thoſe above mentioned (as ſpheres of water may be likewiſe uſed inſtead of glaſs in any of the common *microſcopes*.) But ſince the diſtance of the focus of a lens or ſphere of water is greater than that of one of glaſs, (the ſpheres whereof they are ſegments being the ſame), *water-microſcopes* magnify leſs, and are therefore leſs eſteemed than thoſe of glaſs. The ſame Mr. Gray firſt obſerved, that a ſmall drop or hemiſpherule of water, held to the eye by candle-light or moonlight, without any other apparatus, magnified the animalcule contained in it, vaſtly more than any other *microſcope*. The reaſon is, that the rays, coming from the interior ſurface of the firſt hemiſphere, are reflected ſo as to fall under the ſame angle on the ſurface of the hind hemiſphere, to which the eye is applied, as if they came from the focus of the ſpherule; whence they are propagated to the eye in the ſame manner as if the objects were placed without the ſpherule in its focus.

Hollow glaſs ſpheres, of the diameter of about half a digit, filled with ſpirit of wine, are frequently uſed for *microſcopes*; but they do not magnify near ſo much.

MICROSCOPES, *theory of compound, or double*. Suppoſe an object glaſs ED, *fig.* 56. N° 1.) the ſegment of a very ſmall ſphere, and the object AB placed without the focus F.

Suppoſe an eye-glaſs GH, convex on both ſides, and the ſegment of a ſphere greater (though not too great) than that of DE; and ſet it be ſo diſpoſed behind the object, as that if CF : CL :: CL : CK; the focus of the eye-glaſs may be in K.

Laſtly, ſuppoſe LK : LM :: LM : LI.

If, then, O be the place wherein an object is ſeen diſtinct with the naked eye; the eye, in this caſe, being placed in I, will ſee the object AB diſtinctly, in an inverted ſituation, and magnified in a compound ratio of MK to LK, and LC to CO; as is proved from the laws of dioptrics; i. e. the image itſelf is larger than the object, and we are able to view it diſtinctly at a leſs diſtance. E. gr. If the image be twenty times larger than the object, and by the help of the eye-glaſs we are able to view it five times nearer than we could have done with the naked eye, it will, on both theſe accounts, be magnified 5 times 20, or 100 times.

MICROSCOPES, *laws of double*. 1. The more an object is magnified by the *microſcope*, the leſs is its *field*, i. e. the leſs of it it takes in at one view.

2. To the ſame eye-glaſs may be ſucceſſively applied object-glaſſes of various ſpheres, ſo as that both the entire objects, but leſs magnified, and their ſeveral parts, much more magnified, may be viewed through the ſame *microſcope*. In which caſe, on account of the different diſtance of the image, the tube LK, in which the lenſes are fitted, ſhould be made to draw out. For the proportion of the object-glaſs to the eye-glaſs, ſome commend the ſubduple ratio, and ſome the ſubſeſquitertile. De Chales will have the ſemidiameter of the convexity of the object-glaſs to be $\frac{1}{4}$ of a digit, or, at moſt, $\frac{1}{3}$; in the eye-glaſs an entire digit, or even $1\frac{1}{4}$. Cherubin makes the ſemidiameter of the object-glaſs $\frac{1}{2}$, $\frac{1}{3}$, or $\frac{1}{4}$ of a digit; the ſemidiameter of the eye-glaſs $1\frac{1}{2}$, or $1\frac{1}{3}$ of a digit.

3. Since it is proved, that the diſtance of the image LK from the object-glaſs DE will be greater, if another lens, concave on both ſides, be placed before its focus; it follows, that the object will be magnified the more, if ſuch a lens be here placed between the object-glaſs DE, and the eye-glaſs GH. Such a *microſcope* is much commended by Conradi, who uſed an object-lens, convex on both ſides, whoſe ſemidiameter was two digits, its aperture equal to a muſtard-ſeed; a lens, concave on both ſides, 12, or at moſt 16 digits; and an eye-glaſs, convex on both ſides, of 6 digits.

4. Since the image is projected to the greater diſtance, the nearer another lens, of a ſegment of a larger ſphere, is brought to the object-glaſs; a *microſcope* may be compoſed of three lenſes, which will magnify prodigiouſly.

5. From theſe conſiderations it follows, that the object will be magnified the more, as the eye-glaſs is the ſegment of a ſmaller ſphere; but the field of viſion will be the greater, as the ſame is a ſegment of a larger ſphere. If, then, two eye-glaſſes, the one a ſegment of a larger, the other of a ſmaller ſphere, be ſo combined, as that the object appearing very near through them, i. e. not

farther diſtant than the focus of the firſt, be yet diſtinct; the object, at the ſame time, will be exceedingly magnified, and the field of viſion much greater than if only one lens was uſed; and the object will be ſtill more magnified, and the field enlarged, if both the object and eye-glaſs be double. But in regard an object appears dim, when viewed through ſo many glaſſes, part of the rays being reflected in paſſing through each, the multiplying of lenſes is not adviſeable; and the beſt, among compound *microſcopes*, are thoſe which conſiſt of one object-glaſs, and two eye-glaſſes.

Dr. Hooke tells us, in the preface to his Micrography, that in moſt of his obſervations he uſed a *microſcope* of this kind, with a middle eye-glaſs of a conſiderable diameter, when he wanted to ſee much of the object at one view, and took it out when he would examine the ſmall parts of an object more accurately; for the fewer refractions there are, the more light and clear the object appears.

For a *microſcope* of three lenſes, De Chales commends an object-glaſs of $\frac{1}{3}$ or $\frac{1}{4}$ of a digit; and the firſt eye-glaſs he makes 2, or $2\frac{1}{2}$ digits; the diſtance between the object-glaſs and eye-glaſs about twenty lines. Conradi had an excellent *microſcope*, the object-glaſs whereof was half a digit, and the two eye-glaſſes (which were placed very near) four digits; but it anſwered beſt, when, in lieu of the object-glaſs, he uſed two glaſſes, convex on both ſides, their ſphere about a digit and a half, or at moſt two, and their convexities touching each other within the ſpace of half a line. Euſtachius de Divinis, inſtead of an object-glaſs, convex on both ſides, uſed two plano-convex lenſes, whoſe convexities touched; Grindelius did the ſame, only that the convexities did not quite touch. Zalmius made a binocular *microſcope*, wherein both eyes were uſed.

It is obſerved, that compound *microſcopes* ſometimes exhibit a fallacious appearance, by repreſenting convex objects concave, and *vice verſâ*. See Phil. Tranſ. N° 476, p. 387.

MICROSCOPE, *ſtructure or mechaniſm of a double.* The induſtry and addreſs of our countryman, Mr. Marſhal, here deſerves to be remembered: the moſt commodious *double microſcope* is of his contrivance. In this, the eye-glaſs is at W (*fig.* 57.) the object-glaſs at C, the middle glaſs at A 1; B is the cover or lid, to keep out the duſt from the eye-glaſs W; X is the place of the eye, W a ſcrew where the eye-glaſs lies; A a ſcrew where the middle glaſs lies; A the draw, where the outermoſt tube A 1 A 2 is diſjoined from the inner one, of the ſame length; Z the frame or baſis on which the *microſcope* ſtands firm; T a ſmall drawer in the frame or baſis, with a ledge or till in it, having ſix partitions to hold ſo many ſeveral object-glaſſes, one magnifying more than another, and fixed in braſs cells ready to ſcrew on at C, and marked 1, 2, 3, 4, 5, 6; theſe partitions are alſo marked 1, 2, 3, 4, 5, 6; the other part of the drawer ſerves to hold the object-plate *a*; a pair of ſmall nippers *b*, to take up, or handle any object conveniently; another object-plate *d*, having one ſide white and the other black, to fix your objects upon, as black upon white, and white objects on black. L, M, is a braſs ball and ſocket, on which the whole body of the *microſcope* is moveable, ſo as to lie in any poſition for the light. K, O, a ſquare braſs pillar, on which the *microſcope* is moveable up and down, by means of the collar E, into which the arm D (holding the *microſcope*) is continued. G another braſs collar ſliding up and down on the pillar KO, having a ſmall ſcrew H, by which it is, as occaſion ſerves, fixed faſt to the ſaid pillar, at any height. I a large braſs nut, in whoſe center is a female ſcrew, fitted to the male ſcrew F, which is fixed in the collar E; by the turning of which nut I (the collar G being firſt fixed to the pillar by the ſcrew H) the *microſcope* is raiſed up or down on the pillar, and made to come nearer or go farther from the object P *c*; and, which is alſo a very great advantage, the axis of the *microſcope* is always kept perpendicular to that point of the object, over which it was firſt placed; ſo that here is not the inconvenience which occurs in other glaſſes, of often loſing the ſight of the object, by ſcrewing the glaſs C higher or lower. PQ is a glaſs object-plate fixed in a braſs frame, whoſe arm NN is fixed to the pillar by means of the nut O. The arm NN hath in it a ſlit, by which it is eaſily put on, or taken off the pillar, and by which it may be fixed upon it at any diſtance. P a ſmall diſh lying on the glaſs-plate, that the circulation of the blood may be ſeen in the end of the tail-fiſh at *c*. R a convex glaſs, by whoſe help a bright ſpot of light is brought from a candle at S, ſtanding on the ground, while the *microſcope* ſtands on the edge of a table or ſtool, which ſpot of light *c* ſerves to render the circulation more conſpicuous. V a lead coffin to be put on the fiſh, to hinder it from ſpringing away, and moving his tail out of the light. 1, 2, 3, 4, 5, 6, are marks on the pillar KO, to ſhew the reſpective diſtances of the object-glaſs from the object you look upon, according as the object-glaſſes you make uſe of magnify more or leſs: Thus, for inſtance, if you uſe the object-glaſs 5 or 6 (either of which will ſhew the circulation of the blood) you muſt fix the upper edge of the collar E, at the mark 5 or 6 on the pillar. And then the *microſcope* will be very near its exact diſtance from the object; ſo that by a ſmall turn or two of the nut I one way or the other, to be found by trial, you may ſoon fit it exactly to your own eye.

By this *microſcope* liquors alſo may be very commodiouſly examined; for if you place a ſmall drop of any liquor on the glaſs-plate juſt in the middle of the ſpot of light *c*, the parts of it will become very viſible, and its animalcula, if it have any, will be diſcovered. And thus may the eels in vinegar, the ſmall creatures in black-pepper water, or in waters where wheat, barley, &c. has been infuſed, the eels and other ſmall living creatures in puddle-water, be as plainly ſeen as by almoſt any other *microſcope*.

In the *microſcope*, in which the objects are illuminated by reflection, made by Mr. Culpeper and Mr. Scarlet, as an improvement of Mr. Marſhal's, the inner tube *ab*, (*fig.* 58.) which ſlides in the outer *cd*, holds all the glaſſes. The eye-glaſs is at *a a*, the broad middle glaſs at *bb*, and the object-glaſs, being fixt in a button at *e*, is ſcrewed upon the end of a narrower tube *fg*; which being fixed in the baſe of the inner tube, paſſes freely through a hole in the baſe of the outer. The buttons that contain the ſeveral object-glaſſes are marked 1, 2, 3, &c. and the convexity of the inner tube is alſo marked with dotted circles, numbered 1, 2, 3, &c. in order to bring that circle to coincide with the mouth *ee* of the outer tube, whoſe number is the ſame as that of the object-glaſs then made uſe of. But if the object does not yet appear quite diſtinct, the button *e* upon the ſnout *fg* muſt be gradually unſcrewed, to bring the glaſs nearer to the object placed below it. Of theſe glaſſes the greater magnifiers are known by their having ſmaller apertures.

The baſe *dd* of the outer tube is ſupported by three braſs pillars, fixed into a wooden pedeſtal *hh*; and a little below the object-glaſs *f*, a circular plate *iii* is lodged like a ſtage between the pillars, three ſemicircular notches being cut in its circumference to receive the pillars, and to reſt upon three rings that ſurround them. Three ſmall braſs circles *mm*, with holes through the middle of them, are to be placed over the hole *k* in the middle of the ſtage; and then the ivory plate *o* may be put between the two uppermoſt of theſe circles, which are preſſed together by a ſpiral ſpringing wire lodged between the two undermoſt; the two outermoſt being held together by three ſmall pillars paſſing through three holes in the circumference of the middle circle. For viewing the circulation of the blood, the button *p*, on the under ſide of the frame of a broad plane glaſs *qr*, being put through a ſlit *i*, made in the ſtage, a ſmall braſs plate *s*, under the ſtage, muſt be moved inwards, till a ſmaller ſlit in it embraces the neck of the ſaid button; and then the fiſh being laid upon this glaſs, and covered with the coffin *t*, its tail may be brought exactly under the object-glaſs by turning the glaſs *pq* about the button, or by ſhoving it inwards or outwards along the ſlit *i* in the ſtage. The circular object-plate *uu* has a like button in its center, to be put into the ſame ſlit as before; and then the different objects, placed between two tales in the holes made round the circumference of the plate, may be viewed ſucceſſively by turning the plate about its center.

All theſe tranſparent objects are illuminated extremely well in this *microſcope*, either by candle-light or ſky-light reflected upwards from a concave looking-glaſs *vz*, placed in a frame upon the center *b* of the pedeſtal. While you are viewing the object through the *microſcope*, turn this concave upon its horizontal poles *y*, *z*, and you will ſoon find out that poſition of it wherein it reflects the moſt light through the hole *k* upon the object; and this happens when it reflects the rays very obliquely. Opake objects, when laid upon a black ebony or a white ivory plate, put into the hole *k* upon the ſtage, may be illuminated by candle-light tranſmitted through a double convex lens *aa*; the foot *y*, of the frame *ay*, in which it turns, being put into the hole *l* in the ſtage. The candle muſt be placed in a line drawn from the object through the middle of this lens, at ſuch a diſtance from it as ſhall cauſe the ſpot of light upon the object-plate to be the narroweſt. By day-light this lens gives little or no advantage to the direct ſky-light.

To fit *microſcopes*, as well as TELESCOPES, to ſhort-ſighted eyes, the object-glaſs and the eye-glaſs muſt be placed a little nearer together, ſo that the rays of each pencil may not emerge parallel, but may fall diverging upon the eye.

MICROSCOPE, *reflecting*, is, properly, that which magnifies by reflection, as the above mentioned ones do by refraction.

The ſtructure of ſuch a *microſcope* may be conceived thus: near the focus of a concave ſpeculum, AB (*fig.* 59.) place a minute object C, that its image may be formed larger than itſelf in D; to the ſpeculum join a lens, convex on both ſides, EF, ſo as the image D may be in its focus.

The eye will here ſee the image inverted, but diſtinct, and enlarged; conſequently, the object will be larger than if viewed through the lens alone.

The inventor of this *microſcope* is the great Sir I. Newton; but the objects appear dim in it.

Any teleſcope is converted into a *microſcope*, by removing the object-glaſs to a greater diſtance from the eye-glaſs. And ſince the diſtance of the image is various, according to the diſtance of the object from the focus; and it is magnified the more, as its diſtance from the object-glaſs is greater; the ſame teleſcope may be ſucceſſively converted into *microſcopes*, which magnify the object in different degrees.

The conſtruction of this *microſcope* is more particularly explained in *fig.* 60. in which, inſtead of the lens d e f, there is placed a ſmall ſpeculum *d e f*; ſo that the object *a c b* being placed above it, at a little greater diſtance from the focus *g*, has its image ACB, formed by reflexion, as in the other caſe it was by refraction, through the lens d f. Now if we ſuppoſe the focal diſtance of the object ſpeculum *d e f*, and lens d e f the ſame, the effect of the *microſcope* will, in other reſpects, be the ſame alſo.

For the diſtance of the object *a b* above the ſpeculum, will be equal to the diſtance of the object a b below the lens, in order that the image may be formed at the ſame diſtance C*c*. The poſition of the object will be inverted; for all the rays flowing from the point *a*, will be reflected by the ſpeculum to the point A, in the ſame manner as if they came by refraction through the lens from the point *a*. Thus the part *b* in the object will be reflected to the focus B in the image, which, therefore, is inverted. The power of magnifying will alſo be the ſame in this and in the reflecting TELESCOPE of a ſimilar conſtruction. For ſince the image AB and the object *a b* are ſeen under equal angles from the vertex *e* of the ſpeculum, the triangles *a e b*, and A*e* B will be ſimilar, and therefore A B : *a b* :: C*e* : *e e*; but in the other it is AB : a b :: C*e* : *e e*. But the latter ratio of theſe analogies is the ſame in both, and conſequently the firſt is ſo too. This *microſcope* is not ſo eaſy to manage as the common ſort. For viſion by reflexion, as it is much more perfect, ſo it is far more difficult than that by refraction. Nor is this *microſcope* ſo uſeful for any but very ſmall, or tranſparent objects. For the object, being between the ſpeculum and image, would, if it were large and opake, prevent a due reflexion.

In Dr. Smith's reflecting *microſcope* there are two reflecting mirrors, one concave and the other convex, and the image is viewed by a lens. To explain it, let AD, (*fig.* 61.) be a large concave ſpeculum, and *a d* a ſmall convex one, each perforated in the middle with the holes BC, *b c*. Both theſe are ſegments of the ſame ſphere, or ground on tools of an equal radius, viz. of two inches, that ſo the focal diſtance of each ſpeculum may be juſt one inch.

Theſe two ſpeculums are placed at the diſtance of about 1⅝ inch from each other, that ſo an object OPQ, being placed a little below the ſmaller ſpeculum, might be between the focus F and center E of the larger ſpeculum. Things thus circumſtanced, the rays PA, PD, which flow from the point P in the object, on the ſpeculum AD, will be reflected towards a focus *p*, where an image *o p q* would be formed, if the rays were not intercepted by the convex ſpeculum *a d*; and the point *p* being nearer than its focus *f*, the rays A*o*, D*d*, which tend or converge towards it, will be reflected to a focus *P*, where the laſt image, *OPQ*, will be formed, to be viewed through the eye-glaſs G, by the eye at I.

This *microſcope*, though far from being executed in the beſt manner, performed, Dr. Smith ſays, nearly as well as the very beſt refracting *microſcopes*; ſo that he did not doubt but that it would have excelled them, if it had been executed properly. Dr. Smith's own account of this inſtrument may be ſeen in his Opticks Remarks, p. 94.

MICROSCOPE, *ſolar*, called alſo the camera obſcura *microſcope*, was invented by Mr. Lieberkuhn in 1738 or 1739, and is compoſed of a tube, a looking-glaſs, a convex lens, and a Wilſon's *microſcope*. The tube (*fig.* 62.) is braſs, near two inches in diameter, fixed in a circular collar of mahogany, with a groove on its periphery on the outſide, denoted by 2, 3, and connected by a cat-gut to the pulley 4 on the upper part; which turning round at pleaſure, by the pin 5 within, in a ſquare frame, may be adjuſted eaſily to a hole in the ſhutter of a window, by the ſcrews 1, 1, in ſuch a manner that no light can paſs into the room but through the aforeſaid tube. Fattened to the frame by hinges, on the ſide that goes without the window, is a looking-glaſs G, which, by means of a jointed braſs-wire, 6, 7, and the ſcrew H 8, coming through the frame, may be moved either vertically or horizontally, to throw the ſun's rays through the braſs tube into the darkened room. The end of the braſs tube without the ſhutter has a convex lens, 5, to collect the rays, thrown on it by the glaſs G, and bring them to a focus in the other part, where D is a tube ſliding in and out, to adjuſt the object to a due diſtance from the focus; and to the end G of another tube F, is ſcrewed one of Wilſon's ſimple pocket *microſcopes*, containing the object to be magnified in a ſlider; and by the tube F, ſliding on the ſmall end E of the other tube D, it is brought to a true focal diſtance.

The ſolar *microſcope* has been introduced into the ſmall and portable, as well as the large CAMERA *obſcura*; and if the image be received upon a piece of half-ground glaſs, ſhaded from the light of the ſun, it will be ſufficiently viſible. M. Lieberkuhn made conſiderable improvements in his ſolar *microſcope*, particularly in adapting it to the view of opake objects; and M. Æpinus, Nov. Com. Petrop. vol. ix. p. 326, has contrived, by throwing the light upon the foreſide of any object, before it is tranſmitted through the object lens, to repreſent with equal advantage all kinds of objects by it. In this improvement, the body of the common ſolar *microſcope* is retained, and only an addition made of two braſs plates, C A and B A (*fig.* 63.) joined by a hinge, and kept at a proper diſtance by a ſcrew. A ſection of theſe plates, and of all the neceſſary parts of the inſtrument, may be ſeen in *fig.* 64. where *r*, *a*, repreſent rays of the ſun converging from the illuminating lens, and falling upon the mirror *d b*, which is fixed to the nearer of the braſs plates. From this they are thrown upon the object at *e f*, and thence are tranſmitted through the object lens at *k*, and a perforation in the farther plate, upon a ſcreen, as uſual. The uſe of the ſcrew *n* is to vary the diſtance of the two plates, and thereby to adjuſt the mirror to the object with the greateſt exactneſs. For Mr. Euler's method of introducing viſion by reflected light into this *microſcope*, ſee MAGIC *lantern*.

The MICROSCOPE *for opake objects* was alſo invented by M. Lieberkuhn about the ſame time with the former, and remedies the inconvenience of having the dark ſide of an object next the eye; for by means of a concave ſpeculum of ſilver, highly poliſhed, in whoſe center a magnifying lens is placed, the object is ſo ſtrongly illuminated, that it may be examined with eaſe. A convenient apparatus of this kind, with four different ſpeculums and magnifiers of different powers, was brought to perfection by Mr. Cuſſ. Phil. Trans. N° 458. § 9.

MICROSCOPIC *objects*. All things too minute to be viewed diſtinctly by the naked eye, are proper objects for the *microſcope*. Dr. Hooke has diſtinguiſhed them to be exceeding ſmall bodies, exceeding ſmall pores, or exceeding ſmall motions.

Exceeding ſmall bodies muſt either be the parts of larger bodies, or things, the whole of which is exceedingly minute, ſuch as ſmall ſeeds, inſects, ſands, ſalts, &c.

Exceeding ſmall pores are the interſtices between the ſolid parts of bodies, as in ſtones, minerals, ſhells, &c. or the mouths of minute veſſels in vegetables, or the pores in the ſkin, bones, and other parts of animals.

Exceeding ſmall motions are the movements of the ſeveral parts or members of minute animals, or the motion of the fluids, contained either in animal or vegetable bodies. Under one or other of theſe three heads, almoſt every thing about us affords us matter of obſervation, and may conduce both to our amuſement and inſtruction.

An examination of theſe objects, however, ſo as to diſcover truth, requires a great deal of attention, care, and patience, with ſome ſkill and dexterity, to be acquired chiefly by practice, in the preparing, managing, and applying them to the *microſcope*.

Whatever object offers itſelf as the ſubject of our examination, the ſize, contexture, and nature of it, are firſt to be conſidered, in order to apply it to ſuch glaſſes, and in ſuch a manner as may ſhew it beſt. The firſt ſtep ſhould always be to view the whole together, with ſuch a magnifier as can take it in all at once; and after this the ſeveral parts of it may the more fitly be examined, whether remaining on the object, or ſeparated from it. The ſmaller the parts are which are to be examined, the more powerful ſhould be the magnifiers employed; the tranſparency or opacity of the object muſt alſo be conſidered, and the glaſſes employed accordingly ſuited thereto; for a tranſparent object will bear a much greater magnifier than one which is opake, ſince the nearneſs

that

that a glass must be placed at, unavoidably darkens an object if in its own nature opake, and renders it very difficult to be seen, unless by the help of the apparatus contrived for that purpose, which has a silver speculum. Most objects however become transparent by being divided into extremely thin parts.

The nature of the object also, whether it be alive or dead, solid or a fluid, an animal, a vegetable, or a mineral substance, must likewise be considered, and all the circumstances of it attended to, that we may apply it in the most advantageous manner. If it be a living object, care must be taken not to squeeze or injure it, that we may see it in its natural state and full perfection. If it be a fluid, and that too thick, it must be diluted with water; and if too thin, we should let some of its watery parts evaporate. Some substances are fitteſt for observation when dry, others when moiſtened; ſome when freſh, and others after they have been kept ſome time.

Light is the next thing to be taken care of; for on this the truth of all our obſervations depends; and a very little obſervation will ſhew how very different objects appear in one degree of it to what they do in another; ſo that every new object ſhould be viewed in all degrees of light, from the greateſt glare of brightneſs to perfect obſcurity, and that in all poſitions to each degree, till we hit upon the certain form and figure of it. In many objects it is very difficult to diſtinguiſh between a prominency and a depreſſion, a black ſhadow and a black ſtain, and in colour between a bright reflection and whiteneſs. The eye of a fly in one kind of light appears like a lattice drilled full of holes, in the ſun-ſhine like a ſolid ſubſtance covered with golden nails; in one poſition like a ſurface covered with pyramids, in another with cones, and in others with ſtill different ſhapes.

The degree of light muſt always be ſuited to the object; if that be dark, it muſt be ſeen in a full and ſtrong light; but if tranſparent, the light ſhould be proportionably weak; for which reaſon there is a contrivance both in the ſingle and double microſcope to cut off abundance of the rays, when ſuch tranſparent objects are to be examined by the largeſt magnifiers. The light of a candle for many objects, and eſpecially for ſuch as are very bright and tranſparent, and very minute, is preferable to day-light; for others a ſerene day-light is beſt; but ſun-ſhine is the worſt light of all, for it is reflected from objects with ſo much glare, and exhibits ſuch gaudy colours, that nothing can be determined from it with any certainty. This, however, is not to be extended to the ſolar, or *camera obſcura microſcope*; for in that nothing but ſun-ſhine can do, and the brighter that is the better; but in that way we do not ſee the object itſelf on which the ſun-ſhine is caſt, but only the image or ſhadow of it exhibited on a ſcreen; and therefore no confuſion can ariſe from the glaring reflection of the ſun's rays from the object to the eye, which is the caſe in other *microſcopes*. But then in that ſolar way we muſt reſt contented with viewing the true form and ſhape of an object, without expecting to find its natural colour; ſince no ſhadow can poſſibly wear the colour of the body it repreſents.

Moſt objects require alſo ſome management, in order to bring them properly before the glaſſes. If they are flat and tranſparent, and ſuch as will not be injured by preſſure, the beſt way is to incloſe them in ſliders between two Muſcovy tales or iſinglaſſes. In this way the feathers of butterflies, the ſcales of fiſhes, and the farinæ of flowers, may be very conveniently preſerved, as alſo the parts of inſects, the whole bodies of minute ones, and a great number of other things. Theſe are to be kept in ſliders, each containing three, four, or more holes, and theſe muſt not be filled promiſcuouſly; but all the things preſerved in one ſlider ſhould be ſuch as require one and the ſame magnifying power to view them, that there may not be a neceſſity of changing the glaſſes for every object; and the ſliders ſhould be marked with the number of the magnifier it is proper to be viewed with. In placing the objects in the ſliders, it is always proper to have a ſmall magnifier, of about an inch focus, in your hand, to examine and adjuſt them by, before they are fixed down with the rings.

Small living objects, ſuch as lice, fleas, bugs, mites, minute ſpiders, &c. may be placed between theſe tales without injuring them, if care be taken to lay on the braſs rings without preſſing them down, and they will remain alive many weeks in this manner; but if they are too large to be treated thus, they ſhould be either preſerved between two concave glaſſes, or elſe viewed immediately, by holding them in the pliers, or ſticking them on the point at the other end of that inſtrument.

If fluids come under examination, to diſcover the animalcules in them, a ſmall drop is to be taken with a hair-pencil, or on the nib of a clean pen, and placed on a plate of glaſs; and if they are too numerous to be thus ſeen diſtinctly, ſome water warmed, by holding it in the mouth, muſt be added to the drop, and they will then ſeparate, and be ſeen diſtinctly. This is particularly neceſſary in viewing the animalcules in the *ſemen maſculinum* of all creatures; which, though extremely minute, are always ſo numerous, that without this caution their true form can ſeldom be ſeen. But if we are to ſee the ſalts in a fluid, the contrary method muſt be obſerved, and the plate of glaſs muſt be held gently over the fire, till part of the liquor is evaporated.

The diſſection of minute animals, as lice, fleas, &c. requires patience and care; but it may be done very accurately by means of a needle and a fine lancet, placing the creature in a drop of water, for then the parts will readily unfold themſelves, and the ſtomach, guts, &c. be very diſtinctly ſeen.

Theſe ſeem the beſt ways of preſerving tranſparent objects; but the opake ones, ſuch as ſeeds, woods, &c. require a very different treatment, and are beſt preſerved and viewed in the following manner.

Cut cards into ſmall ſlips about half an inch long, and a tenth of an inch broad; wet theſe half way of their length in gum-water, and with that faſten on ſeveral parcels of the object, and as the ſpots of cards are of different colours, ſuch ſhould be choſen for every object as are the moſt different from its own colours. Theſe are very convenient for viewing by the *microſcope* made for opake objects with the ſilvered ſpeculum; but they are proper for any *microſcope* that can view opake bodies.

A ſmall box ſhould be contrived for theſe ſlips, with little ſhallow holes for the reception of each; and this is conveniently done, by cutting pieces of paſte-board, ſuch as the covers of books are made of, to the ſize of the box, ſo that they will juſt go into it, and then cutting holes through them with a ſmall chiſſel, of the ſhape of the ſlips of card, theſe paſte-boards having then a paper paſted over their bottom, are cells very proper for the reception of theſe ſlips, which may be taken out by means of a pair of plyers, and will be always ready for uſe.

Great caution is to be uſed in forming a judgment on what is ſeen by the *microſcope*, if the objects are extended or contracted by force or drineſs.

Nothing can be determined about them, without making the proper allowances; and different lights and poſitions will often ſhew the ſame object as very different from itſelf. There is no advantage in any greater magnifier than ſuch as is capable of ſhewing the object in view diſtinctly; and the leſs the glaſs magnifies, the more pleaſantly the object is always ſeen.

The colours of objects are very little to be depended on, as ſeen by the *microſcope*; for their ſeveral component particles being by this means removed to great diſtances from one another, may give reflections very different from what they would, if ſeen by the naked eye.

The motions of living creatures alſo, or of the fluids contained in their bodies, are by no means to be haſtily judged of, from what we ſee by the *microſcope*, without due conſideration; for as the moving body, and the ſpace wherein it moves, are magnified, the motion muſt be ſo too; and therefore that rapidity with which the blood ſeems to paſs through the veſſels of ſmall animals muſt be judged of accordingly. Suppoſe, for inſtance, that a horſe and a mouſe move their limbs exactly at the ſame time, if the horſe runs a mile while the mouſe runs fifty yards; though the number of ſteps are the ſame in both, the motion of the horſe muſt notwithſtanding be allowed the ſwifteſt; and the motion of a mite, as viewed by the naked eye, or through the *microſcope*, is perhaps not leſs different. Baker's Microſcope, p. 52. 62. See *Table of* MICROSCOPIC *objects*.

MICTUS *cruentus*. See *Bloody* URINE.

MID, or MIDDLE, in *Philoſophy* and *Mathematics*. See MEAN, and MEDIUM.

MIDDLE *latitude*, in *Navigation*, is half the ſum of two given latitudes.

MIDDLE *latitude ſailing*, is uſed for a method of working the ſeveral caſes in ſailing, nearly agreeing with Mercator's way, but without the help of meridional parts. See SAILING.

MIDDLE *region*. See REGION.

MID-*feather*, in the Engliſh *Salt-Works*, the name given to a ſort of partition placed in the middle of the furnace, over which the pan is ſet for boiling the ſea-water or brine into ſalt.

This partition divides the body of the furnace into two chambers. See SALT.

MID-HEAVEN, *medium cœli*, in *Aſtronomy*, is that point of the ecliptic which culminates, or is in the meridian. See CULMINATION.

MIDA, in *Natural Hiſtory*, the name of a worm or maggot,

got, of which is produced the purple-fly, found on bean-flowers, and thence called the bean-fly.

MIDAD *nlbendi*, in the *Materia Medica of the Arabians*, a name given to the common indigo blue.

The express meaning of the words is India ink; but this is an erroneous name, founded on Pliny's misunderstanding the words of Dioscorides. The Greeks in general have called the common writing ink *melan*; but they have also used this word *melen* as an adjective, expressive not only of black, but of deep blue. Thus Theophrastus has called both the violet flowers and the fine deep blue sapphires, *melanes*. Pliny, finding him call the indigo when of a very fine and deep colour, *melan Indicon*, thought it to be different from the common indigo, and thence supposed it a sort of Indian ink. Thus Indian ink has become a sort of name for this blue.

MIDAS's *ear-shell*, in *Conchyliology*. See TRUMPET-*shell*.

MIDDLING-*teeth*, in the *Manage*, are the four teeth of a horse that come out at three years and a half, in the room of other four foal-teeth, seated between the nippers and the corner-teeth; from which situation they derive the title of *middling*. There is one of them above, and one below, on each side of the jaws. See TEETH.

MIDRIFF, in *Anatomy*. See DIAPHRAGM.

MIDSHIP, is a term of distinction, applied by shipwrights to several pieces of timber which lie in the broadest part of the vessel.

MIDSHIP-*beam*, is the beam upon which the extreme breadth of the ship is formed, and which is situated in the *midship* frame, nearly in the middle of her length, serving as a standard from whence the dimensions and proportions of the masts and yards are to be taken. See BEAM.

MIDSHIP-*frame*, is a name given to that timber, or combination of pieces, formed into one timber, which determines the extreme breadth of the ship, as well as the figure and dimension of all the inferior timbers.

MIDSHIP-*men*, are officers on board a ship of war, whose station, when they are on duty, is, some on the quarter-deck, others on the poop, &c.

Their business is, to mind the braces, to look out, and to give about the word of command from the captain, and other superior officers. They all assist, on occasion, both in sailing the ship, and in stowing and rummaging the hold; and in performing the necessary business of the vessel, either aboard or ashore. The number of *midshipmen*, like that of all other officers, is always in proportion to the size of the ship to which they belong. Thus, a first-rate man of war has twenty-four, and the inferior rates a suitable number in proportion. No person can be appointed a LIEUTENANT, without having previously served two years in the royal navy in this capacity, or in that of MATE, besides having been at least four years in actual service at sea, either in merchant-ships, or in the royal navy.

MIDSUMMER-*day*, is the festival of St. John the Baptist, held on the 24th of June. See QUARTER-*day*.

MIDYON, a word used by Theophrastus, as the name of a species of oak. It is prescribed by some of the old physicians, in their compositions; but is usually supposed to stand there by an error of the copies; the word meant being *misy*.

MIERES, a name by which some writers have called ASPHALTUM.

MIGRATION, or TRANSMIGRATION, the passage or removal of any thing out of one state, or place, into another; particularly of colonies of people, birds, &c. into other countries.

The *migration of the souls of men* into other animals after death, is the great doctrine of the Pythagoreans, called the METEMPSYCHOSIS.

The *migration of birds*, as the swallow, quail, stork, crane, fieldfare, woodcock, nightingale, and other birds of PASSAGE, is a very curious article in natural history, and furnishes a notable instance of the powerful instinct impressed by the Creator. Dr. Derham observes two things remarkable therein; the first, that these untaught, unthinking creatures, should know the proper times for their passage, when to come, and when to go; as also, that some should come when others go. No doubt, the temperature of the air, as to heat and cold, and their natural propensity to breed their young, are the great incentives to those creatures to change their habitation. But why should they at all shift their habitation? and why is not some certain place to be found, in all the terraqueous globe, affording them convenient food and habitation all the year round?

The second, that they should know what way to steer their course, and whither to go? What instinct is it, that moves a poor foolish bird to venture over vast tracts of land and sea? if it be said, that, by their high ascents up into the air, they can see across the seas; yet what should teach or persuade them, that another land is more proper for the purpose than this? that Britain, for instance, should afford them better accommodation than Egypt? than the Canaries? than Spain? or any other of the intermediate countries? Physico-Theol. p. 234.

Lud. de Beaufort remarks, that birds, in their *migrations*, observe a wonderful order and polity: they fly in troops, and steer their course through vast unknown regions without the compass. Cosmol. Divin. It is to be added, that the birds of passage are all peculiarly accommodated, by the structure of their parts, for long flights.

Naturalists are divided as to the places whither birds of passage retire when they leave us. Mr. Willughby thinks the swallows fly into Egypt and Ethiopia.

Olaus Magnus says, they lurk in holes, or under water; which is confirmed by Bemuller, who assures us, that he saw a bushel of them taken out of a frozen fish-pond, all hanging together, head to head, feet to feet, &c. in one cluster. Disert. n. c. 10. Olaus adds, that this is a common thing in the northern countries; and that such a cluster being carried accidentally by some boys into a stove, the swallows, after thawing, began to fly about, but weakly, and only for a very little time.

A farther confirmation of this account was given by Dr. Colas, a person very curious in such things, to the Royal Society. Speaking of the way of fishing in the northern parts, by breaking holes, and drawing their nets under the ice, he related, that he saw fifteen swallows so drawn out of the lake of Samrodt, and about thirty out of the king's great pond in Rofnellen; and that at Schlebitten, near a house of the earl of Dohna, he saw two swallows just come out of the waters that could scarce stand, being very wet and weak, with their wings hanging on the ground. He added, that he had often observed the swallows to be weak, for some days, after their first appearance.
